"SALUS POPULI SUPREMA LEX."

VOL. CXXXIX.

WEDNESDAY, JULY 7, 1909.

No. I.

## NOTES AND COMMENTS.

Messrs.  
Cadbury—

ONE of the great difficulties that confronts those who are interested in the public health is the problem how to procure proper health conditions for workers in factories. The "urban-trend" of the population of these isles is a great fact which has to be faced, and though the excellent Small Holdings Act, passed two years ago by the Government, may do something to keep agricultural labourers *in situ*, and to attract to the land the more sturdy of town-workers, the fact remains that industrial pursuits and town life continue to draw an enormous number of workers to the great centres of industry. It is all very well, and it is certainly very proper, to make regulations for the sanitary conduct of factories, schools and other large buildings, but the problem of the home remains to be solved, and even the most ardent local administrator cannot succeed in providing healthy houses and healthy conditions of life for workers who have not the instinct of cleanliness and decent living. An admirable example of what may, and has been, done through private enterprise by a firm which has its servants' interests at heart is shown by a little pamphlet issued by Messrs. Cadbury on the growth of their business in the last thirty years, and the way in which they have simultaneously coped with allied difficulties in keeping their staff well provided for in the matter of home life. In this pamphlet is set forth a table showing the growth of the number of workers employed in the factories, which is little less than astonishing. In 1879, 66 men, 140 women, and 24 clerks, travellers, &c., were employed, and in spite of improved machinery, which did away with the necessity of much manual labour, the numbers have steadily risen, till they now reach the gigantic total of 1,563 men, 2,913 women, and 447 travellers, clerks, &c.—4,923 employees in all, as compared with 230 thirty years ago.

And their  
Workers.

MESSRS. CADBURY'S principles with regard to their business is that the efficiency of workers is largely determined by their conditions of living, and consequently they have built a "model" town with "model" houses for the residence of those attending at Bourneville, and have instituted a system of pay whereby the workers have a margin over the necessary "living wage"; no man over twenty-three, married or unmarried, receiving less than 24s. a week for a definite number of hours' work and appropriate holiday conditions, fines being altogether eliminated. A medical officer is attached to the staff, and he is able to show that the sickness-rate is exceedingly low, at present barely 1½ per cent., the first quarter

of this year—considered a heavy one—showing 2.3 weeks per sick worker, against 8.4 weeks per sick member of the leading friendly society. The mortality-rate last year was but 2 per 1,000, and the phthisis mortality but .4 per 1,000—rates which we believe are vastly lower than those existing in any other community. Accidents are very few, only 6, 8 and 7 serious ones having occurred in the last three years, a result largely due to proper inspection of machines and machine-guards. Another point which strikes us forcibly is the abolition of the employment of married women, which was carried out many years ago, and we heartily congratulate Messrs. Cadbury in having secured this most beneficent reform. When we remember that all members get Sundays, Bank Holidays and half Saturdays for holidays, that the hours for women is kept below 42 hours per week, and that the contracts for buying cocoa from the Portuguese islands where cruelties were carried on have been abolished, we may fairly say that Messrs. Cadbury seem to have attained that point in hygiene and healthiness among their workers which all sanitarians are striving for through the whole country.

Medical  
Responsibilities.

AS application of unusual importance to medical men was made in the Divisional Court last week on behalf of a retired greengrocer to compel Dr. Willey to disclose the present address of his (the applicant's) wife. It seems that the woman in question had been a patient at Dr. Willey's establishment suffering from delusions, and on her recovery she had been sent to a farm in the country to get rest and quiet, which she could not obtain at home. An affidavit was read from the wife accusing her husband of cruelty, and saying that it would kill her to return home, and that she was happy and well cared for. Counsel asserted that the real reason the husband wished to get at her was because she possessed money, out of which, it was announced, she made her husband an allowance. It was submitted on behalf of Dr. Willey that an independent medical man should be appointed by the Court to say whether or not the wife was still suffering from delusions. However, the Court refused the application, saying that Dr. Willey could not be ordered to produce the woman who was not in his custody, and that there was no evidence that he had behaved otherwise than perfectly properly. This is an encouraging result, for if the reasons were as stated in the wife's affidavit, it would have been cruel to have allowed the husband access to her, and Dr. Willey showed great courage and sense of duty in protecting his patient by resisting an unreasonable demand.

**The Edinburgh Chair of Surgery.**

THE resignation by Professor Chiene of the Chair of Surgery in Edinburgh University removes a figure that has been familiar to many generations of students. Professor Chiene is now 66 years of age, and his teaching career may be said to have begun in 1866, when he was Demonstrator of Anatomy under Mr. Goodsir and Mr., now Sir William, Turner, and he was closely connected for many years with Mr. Joseph—now Lord, Lister. In 1870 he was appointed Lecturer on Practical Surgery in the Extra-Mural School, and he was later chosen for the Chair of Surgery in the University, on the death of Mr. Spence. In 1900 he was appointed Consulting Surgeon to His Majesty's Forces in South Africa, and for his services in the Boer War he was mentioned in despatches and made a C.B. During this long and distinguished career Professor Chiene has always been extremely popular with students, and it is safe to prophesy that any proposal to create a testimonial fund will meet with hearty support wherever Edinburgh medical graduates and diplomates are to be found, that is to say, from all parts of the world. We doubt if John Chiene has an enemy in the wide world, while it would be hard to find a man with a larger circle of friends and admirers.

## LEADING ARTICLES.

### THE ANNUAL MEDICAL REPORT OF THE LOCAL GOVERNMENT BOARD.

THE Supplement to the Thirty-seventh Annual Report of the Local Government Board, containing the Report of the Medical Officer, has been issued for 1907-08. This is the second Report of the kind signed by Dr. Arthur Newsholme, who succeeded Sir William Power, K.C.B., F.R.S., on his retirement in January, 1908. We are told that the present report, like its immediate predecessor, is concerned almost entirely with work carried out by the predecessor of the present medical officer, whose comments are consequently brief. The Report, indeed, consists chiefly of a summarised statement of what has been done at home as well as in various other parts of the world directly or indirectly concerned with public health progress. Apart from the medical officer's short communication, the bulk of the Report is made up of 254 pages of reports of medical inspectors in appendix, and of a further 191 pages of special bacterial investigations. Turning to the work of the medical inspectors, we find much that is of interest and practical value. A report by Dr. Deane Sweeting deals with enteric fever in the Borough of Leigh, Lancashire, where this disease is endemically prevalent, and produces a death-rate more than twice the mean death-rate for the seventy-six great towns of England and Wales. The official inquiry showed a much greater incidence upon the colliers than upon the rest of the population, and subsequently disclosed most unsatisfactory arrangements for sewage-disposal at the local collieries, both above- and underground. Dr. Theodore Thomson, in his report upon the sanitary circumstances and administration of Yeovil, has drawn attention to many unwholesome conditions in that borough that might readily be removed. Curiously, though, there is an undue prevalence of scarlet fever and diphtheria; the

death-rate in 1908 was 14.80, and the mean annual death-rate for the preceding decade, 1896-1905, 15.01 per 1,000 of the population. A report that demands serious attention is that by Dr. Johnstone on the rural district of Sherborne, in Dorset. The chief local industry is dairy-farming, and about 1,000 gallons of milk are sent out daily to London, Aldershot and other places, besides about 1,000 gallons a day converted into milk powder at a factory. As to sewers and sewage-disposal, no proper system exists in any of the villages of this rural district. The neighbouring river Yeo is seriously polluted with sewage, while the drinking-water supply in three of the constituent parishes "constitutes a serious danger to health." As to the dairy farms, no register is kept of the dairies and cowsheds. The majority of the sheds are ill-lighted and ventilated, their walls filthy, paving deficient, while many of the bartons are in such a condition of filth, caused by manure and mud and stagnant water, as to constitute a nuisance. As a rule, milkers neither wash their hands nor cleanse the cows' udders before milking. "The dairy farmers," Dr. Johnstone remarks, "were more opposed to reform in the personal methods of their milkers than to any proposition in the way of improved ventilation and drainage in the cowsheds. It was said by some farmers that the milkers would not submit to regulations for their personal cleanliness, and that milkers were very difficult to get. Other farmers said that if such regulations were insisted upon they would abandon dairy-farming." After reading this passage, our readers will probably agree with the terse comment of the medical inspector to the effect that the sooner men with these ideas give up dairy-farming the better it will be for the health of children and others who consume the milk. To this may be added the reflection that the sooner the practical control of local sanitary administration is taken away from such men the better for society. Under present conditions they constitute the local authority appointing a medical officer who is removable at will. Lastly, it is open to speculation as to how many a mysterious seizure of illness in London may be due to these filthy cowsheds in Sherborne, where "little or no attempt has been made to enforce the regulations adopted under the Dairies, Cowsheds and Milkshops Order." If the Local Government Board, with a report of this kind in their possession, fail to awake the Sherborne authorities to a strong sense of their duties, then the blame will rest with the central authority. The President of the Board, however, the Right Hon. John Burns, is hardly the man to pigeon-hole a document fraught with so much importance as the one under discussion. His careful consideration has also doubtless been given to the report by Dr. Fures on the five small semi-urban districts in the West Riding of Yorkshire, in the neighbourhood of Huddersfield. A striking picture is drawn of the sanitary evils resulting from the unfortunate fact that these five districts, with estimated populations of 1,435,500, 350,620 and 2,000 persons respectively, were many years ago constituted urban districts. The self-government thus conferred has led to many mischievous results, such as multiplication of poorly-paid officers, difficulty of organising comprehensive schemes for water supply and

sewage, overlapping of work, and the sacrifice of public to private interests. The matter contained in Appendix B is of conspicuous scientific value. Dr. Andrewes has continued his important investigations into the distribution of sewage bacteria in the air of drains. He concludes that the occurrence of such organisms mainly depends upon droplet contamination in splashing. Dr. Newsholme remarks that the importance of the facts recorded by Dr. Andrewes rests in the demonstration that sewage bacteria may be present in the air of a drainage system in ordinary use, and, as a matter of fact, are generally present after splashing has occurred. That consideration, however, is much modified by the observation that the effect of a single act of splashing is transient, lasting only a few minutes. Dr. Andrewes and Dr. Horder have continued their observations on the defence of the body against the pyogenic cocci. Dr. Gordon and Dr. Horder have made considerable advance in an attempt to determine the relative value of various anti-meningococcic sera on the market, claiming to be of prophylactic or curative value in cerebro-spinal meningitis. They found three such sera tested had no prophylactic or curative effect. Normal horse serum, on the other hand, had some small value in prolonging a rabbit's life. The two observers named are investigating more powerful sera recently introduced and some special vaccines. A valuable report has been furnished by Dr. Savage upon mastitis in cows, and its possible relationship to human disease. Dr. Savage thinks it probable that streptococci of the *streptococcus mastitidis* type do not ordinarily cause human sore throat; other points are still under investigation. Dr. Sydney Martin has shown that *streptococcus faecalis* injected into rabbits intravenously produces non-ulcerative vegetative endocarditis of the mitral valve, associated with septicæmia. With regard to the Report generally, it maintains in a conspicuous degree the high standard of excellence which has long since established the reputation of public health study and administration in the United Kingdom upon an unassailable basis.

#### THE ANNUAL ELECTION AT THE ROYAL COLLEGE OF SURGEONS, ENGLAND.

As we foreshadowed in a previous issue, the annual election of members to the Council of the Royal College of Surgeons, which took place on the 1st instant, has proved one of the most interesting of recent times. No fewer than 971 Fellows recorded their votes upon the occasion, a number which establishes a record in the history of these elections. Owing to the introduction of voting papers, a reform for which the Fellows have to thank the Association of Fellows, the method of voting has been reduced to a minimum of trouble; in former days it was necessary for each Fellow voting to attend at the College for the purpose; under the present arrangement, however, a voting paper is issued by the Council to each Fellow whose name appears upon the Postal List, and all that he is required to do is to fill in the paper, with a mark opposite the name of the candidate whom he desires to support, sign it, and return it to the College through the post. Thus but little is required of him in this

regard, while he is relieved of an oftentimes impossible journey to the College for the purpose of taking a personal part in the poll. The result of the election just held must be regarded as a surprise. Of the three retiring councillors who sought re-election, only two—Sir W. Watson Cheyne, Bart., and Mr. Harrison Cripps—have been successful, while the third—Mr. Mayo Robson, who has filled the office of Vice-President of the College—was the last on the list. We believe that this latter incident establishes another record. It is only rarely, as we have previously pointed out, that well-known representative surgeons, retiring from the Council, are not re-elected when they seek re-election. In accounting, however, for the deflection of votes to which Mr. Mayo Robson owed his position at the poll, it is essential to remember that the loyalty of the various medical schools towards their representatives had probably a great deal to do with the result. It is curious somewhat to recall that the first occasion upon which the above well-known surgeon competed for a seat on the Council, he was returned by a large majority at the head of the poll. In those days, however, he was a representative of the Provincial Fellows, and the adopted candidate of the Association of Fellows, which at the time had begun to wield a considerable influence in securing the return of candidates to the Council. Since then the position has changed; Mr. Robson is no longer a Provincial Fellow; he is not connected with any large medical school in London, and the Association of Fellows has ceased its active work. No question of policy was involved in the election just determined. As a matter of fact, at the present moment "College politics" are dead, so far as the Fellows are concerned; moreover, the time seems not to have arrived when the Fellows will make common cause with the members in contending for reforms which mainly affect the latter. Whether a combination within the "Body Corporate and Politic," organised for the purpose of extending the basis of the members' rights will ever be effected remains to be seen. Certainly, without the aid and co-operation of the Fellows, the members' task of contending with the Council seems a hopeless one, despite the patient persistency with which they urge their claims. Of course, it must be perfectly obvious to those who have studied what is known as the "members' question" that the only chance of making progress in their campaign is by securing influence in their favour upon the Council itself. In other words, with the Council unanimously hostile to their proposals, common sense suggests that the members may expect nothing, and experience suggests that in this regard they will not be disappointed. The first point, however, to which the members should direct their attention is to indicate their practical unanimity upon the question of the reforms, the consummation of which they seek to obtain. The body representing them—the Society of Members—we believe only consists of a small part of the total number of members, and this being the case, the natural inference is that the bulk of the members care little whether or not the political basis of their connection with their College is enlarged. THE MEDICAL PRESS AND CIRCULAR has always held an open mind upon this subject; and if the members

showed by an unequivocal unanimity that they were desirous of advancing their political position at the College, we doubt not that they would be accorded much support among the broad-minded Fellows, as well as in the columns of the medical journals.

## CURRENT TOPICS.

### Anti-Vivisection Fiasco.

THE feebleness of the anti-vivisection case is exposed over and over again. To keep the flickering flame of their "horrors" alive they either quote barbarisms carried out in remote times when people were burned alive and the torturing of criminals was countenanced, or they invent imaginary "cruelties," like M. Coleridge's Oxford puppies. Not one of the latter-day "tortures" ever stands a moment's cross-examination. The latest alarm which has been agitated by these false humanitarians is the discovery in the Home Office Inspector's Annual Report of a sentence which drew attention to the fact that an experimenter who only held certificate B, had exposed a certain number of animals to X-rays without their being anaesthetised. None of these experiments were in the least severe, in fact, men, women and children are exposed to the rays every day under precisely the same conditions, but because he had not obtained the particular licence to enable him to operate without an anaesthetic, he committed a technical offence. On being questioned, the Home Secretary detailed these circumstances, and mentioned, moreover, that the experimenter would have received permission without difficulty if he had asked for it, but he had not understood which was the proper certificate to apply for. So this "horror," which we have seen described by all sorts of barbarous terms, is not only no horror at all, but a purely technical business arising out of the stringency of the Act. Scientific men have too much to do, as a rule, to study exhaustively all the details, regulations and administrative details of all the Acts affecting their study, and naturally they rely, like ordinary human beings, on what they are told or what they understand to be needed, and it is remarkable that, under the complicated rules and procedure under the Experiments on Animals Act that so few irregularities occur. In this particular technical transgression the anti-vivisectionists wish the Home Secretary to take legal proceedings. Of course the Home Secretary is not going to expose his office to ridicule by any such farcical proceedings. However, the anti-vivisectionists have their own remedy—they can themselves prosecute at common law or under the Act, and they have their evidence. If they are not prepared to do so, the least they can do is publicly to apologise to the gentleman they have abused. We need hardly say we do not expect them to make such an egregious exhibition of themselves as to do the former, nor anything so honourable as the latter.

### The Anaesthetics Bill.

THE Bill introduced to the House of Commons last week by Dr. Cooper for the control of the administration of anaesthetics is hardly expected to reach the Statute-book. It is probably intended by its author merely to focus discussion, and thereby aid in the framing of legislation in the future. Under this measure medical practitioners and dentists applying for registration on or after January 1st, 1912, would be required to submit evidence of having received theoretical and practical instruction in the administration of anaesthetics,

and any person not a registered medical practitioner or dentist would be prohibited from administering an anaesthetic, except under the immediate direction and supervision of a registered medical practitioner or dentist. In the case of persons dying under an anaesthetic medical men would not be permitted to give certificates of death. We agree with the view that medical men should before registration receive instruction in the art of administering anaesthetics, and it is deplorable that the General Medical Council has not long ago enforced the necessity of such instruction on the licensing bodies. We are still unconvinced, however, that there is any reason why dentists should have special privileges as regards the administration of all anaesthetics. Moreover, one of the greatest abuses as regards the administration of anaesthetics was administration by dental mechanics and surgery attendants, an abuse the Bill appears to perpetuate. We fail to see, moreover, any advantage in forbidding death certificates to be issued in the case of deaths under anaesthetics, until there be some proper means of inquiry into such occurrences. A coroner's jury obviously is not a fit tribunal to conduct the investigation.

### The International Medical Congress.

WE have recently received a circular giving fairly full particulars of the programme of the Sixteenth International Medical Congress, which is to be held from August 29th to September 4th of this year in Budapest. Dr. Pavy is President of the British National Committee, whose list contains many well-known names. The list of reports and communications to be made to the Congress, however, contains very few British names. It would seem, indeed, that the interest in the Congress is somewhat declining, at any rate, in these countries. This is not to be wondered at, as in some of the previous meetings the arrangements were so careless as to prevent those who attended gaining either profit or pleasure. Moreover, owing to our national ignorance of foreign languages, there are comparatively few Englishmen who can, with advantage to themselves, follow a discussion in which four official languages are permitted. It is more than doubtful whether these congresses do much directly to promote science, but in the opportunity given to workers in allied subjects to meet each other, and establish thereby a certain *rapprochement*, they have their function. We note that the International Association of the Medical Press is to hold its meeting before the Congress assembles. Budapest is a charming place for a holiday, and with one of the numerous excursions arranged for attendants at the Congress thrown in, medical men have a chance of a very pleasant change.

### The New Tuberculosis Order, Ireland.

WE published last week an epitome of the Order just issued by the Local Government Board for Ireland under the Tuberculosis Prevention Act (Ireland) of 1908. As our readers know, we have freely criticised this Act during the time it was before Parliament, mainly on the ground that, whilst under it a considerable amount of personal inconvenience and worse might result, its mechanism was of such a character that it could effect but little good. This opinion was held by a large number, if not by the bulk, of the medical profession in Ireland, and we fear that the new Order will do little to remove it. According to the Act, the Order could only be promulgated by the Local Government Board "after consultation" with the

Presidents of the Royal Colleges of Physicians and Surgeons of Ireland. It appears that this condition was placed in the Act without permission either of the Colleges or of their titular heads, and consequently it would not be strange if the "consultation" prescribed by the Act was the mere pretence which is necessary to satisfy the Act. "After consultation" is a vague term, and it would perhaps prove of interest to the public generally, and to the medical profession particularly, if the Local Government Board could see its way to inform them: first, what the consultation was about; secondly, whether it was ever finished; and thirdly, if the answer to the second question is in the affirmative, and whether the Board acted, upon the opinion of the Presidents? If the answer to these questions cannot be given and is unsatisfactory, it is obviously the merest farce to bring the names of the Presidents of the two Colleges into the matter. We express these opinions because we consider the Order to be unsatisfactory, and to impair rather than to strengthen the existing public health laws.

## PERSONAL.

Two young medical men, whose names are reported as Drs. Cook and Crinks, appear to have behaved with much humanity and bravery in the recent catastrophe at Newport. At the risk of their lives they tended the buried workmen on the spot, and were the means of saving several lives. In one instance they amputated a man's crushed feet in order to extricate him, but the unfortunate man died from shock.

SIR W. WATSON CHEYNE, Bart., Mr. W. Harrison Cripps, and Mr. R. Clement Lucas were elected Members of Council of the Royal College of Surgeons, England, at the annual meeting of Fellows.

THE unsuccessful candidates at the College election referred to were: Mr. J. Bland-Sutton, 333 votes; Mr. Walter H. Jessop, 333 votes; Mr. Charles A. Ballance, 261 votes; and Mr. A. W. Mayo Robson, 208 votes. We refer at length to the election in another column.

DR. W. A. MACKAY has been presented by the King of Spain with the White Cross Eagle of Carlos IV. for distinguished surgical aid to the Guardia Civil.

MR. ARTHUR CONNELL, F.R.C.S.E., has been appointed to the Lectureship in Practical Surgery in the University of Sheffield, in succession to Dr. George Wilkinson.

THE Chesterfield Medal in Dermatology given by St. John's Hospital for Diseases of the Skin, Leicester Square, has this year been awarded to C. A. McBride, M.D., L.R.C.P.

ON June 26th, Dr. Frederick Pavy, F.R.S., was presented at Oxford with a silver bowl in commemoration of his eightieth birthday, by the Physiological Society. Professor Gotch, who presided, made a sympathetic speech.

At the annual general meeting of the London Nottinghamshire Society, held on June 24th, Mr. Sydney Stephenson, M.B., F.R.C.S.Ed., was elected President of the Society for 1909-10.

A MEDALLION of Lord Lister, the work of Mr. John Keller, presented by past and present students, was presented by Dr. Barber to the Glasgow Royal Infirmary last week.

THE committee of management of Brompton Hospital invite any lady or gentleman wishing to inspect the sanatorium and to see the patients at work to pay a visit to Frimley on Saturday, July 17th, when

the annual garden party will be held, and at which Princess Christian has announced her intention of being present.

DR. EDWIN SMITH, Assistant Director of the Soudan Medical Department, Khartoum, has been accorded permission by the King to receive and wear the insignia of the Fourth Class of the Imperial Order of the Osmanieh, conferred on him by the Khedive.

THE medical students of Glasgow University met in the Union on June 24th to make a presentation to Professor John Cleland, whose intention to retire from the Chair of Anatomy, which he has occupied for 32 years, has already been intimated. Mr. R. R. Archibald, President of the Students' Union, was in the chair.

THE Anatomical Society of Great Britain and Ireland, which was founded in 1887, on June 25th held its annual summer meeting in Bristol for the first time, the chair being taken by the President, Professor A. M. Paterson, M.D., of Liverpool University. The Conference was well attended by representatives from various parts of England, Ireland, Scotland, and Wales, whilst Professor Ramström, of Upsala, was also present.

At a meeting of the special election committee of the Leeds Infirmary, Mr. L. R. Braithwaite, M.B., Ch.B., F.R.C.S., was appointed hon. assistant surgeon in charge of the Ida and Robert Arthington semi-convalescent hospitals.

A MEETING of the Board of Management of the Manchester Royal Infirmary was held on June 29th, Mr. W. Cobbett (Chairman) presiding, when the following appointments were made:—Mr. Howard Buck, M.B., Ch.B. (Victoria), Surgical Registrar; Mr. R. A. Atkinson, M.B., Ch.B. (Victoria), Junior Anæsthetist.

THE Raymond Horton-Smith Prize in the University of Cambridge for 1909 for the best thesis during the past year for the Degree of Doctor of Medicine has been awarded to Mr. Henry Hallett Dale, M.A., M.B., B.C., of Trinity College. Mr. Cecil Herbert Winter Page, M.A., of Corpus Christi College, was adjudged *Proxime accessit*.

THE Therapeutical and Pharmacological Section of the Royal Society of Medicine will meet at Cambridge on July 10th. There will be demonstrations in the Pharmacological Laboratory by Professor W. E. Dixon and others, and at 6.30 p.m. the annual dinner will be held in the Hall of Downing College.

THE governors and medical staff of Guy's Hospital will give a garden party on Thursday, July 8th, at 3.15 p.m., when the medals and prizes for the year will be distributed to the successful students by his Grace the Duke of Devonshire.

DR. JAMES DOUGLAS, of Quebec and New York, has founded a Douglas Studentship for Research in Actino-Therapeutics, with special reference to cancer, at Guy's Hospital Medical School. The studentship is tenable for one year, is of the value of £300, and is open to all persons who possess a registrable British medical qualification.

THE annual meeting of the Poor-law Medical Officers' Association began yesterday, at the Guildhall, London, the Poor-law medical officers of England and Wales considering the recommendations of the Royal Commission on Poor-law Medical Relief. The conference was opened by the Lord Mayor in the Council Chamber.

PAPERS are being read by Dr. Major Greenwood, D.P.H.; Mr. C. S. Loch, Secretary of the London Charity Organisation Society; Mrs. Sidney Webb; Dr. F. S. Toogood, Medical Superintendent, Lewisham Infirmary; and Dr. G. F. McCleary, M.O.H., Hampstead.

# A CLINICAL LECTURE

## ON

### RECENT EXPERIENCES OF THE SCHÄFER METHOD OF ARTIFICIAL RESPIRATION. (a)

By CLINTON T. DENT, F.R.C.S.,

Surgeon to St. George's Hospital, Chief Surgeon, Metropolitan Police.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

GENTLEMEN,—With regard to the actual *technique* of the Schäfer method of respiration I need say but little. It is founded on the principle of utilising abdominal respiration. It has some features in common with the method which was introduced and which was demonstrated in this country by Dr. Benjamin Howard, of New York. Schäfer's method utilises the fact that in ordinary tranquil breathing the diaphragm sinks with inspiration, and as it sinks it presses forward the epigastrium by pushing down the viscera. Reversing the process and compressing the epigastrium expels the air from the lungs. Schäfer does not desire that the thorax shall be compressed more than is absolutely necessary. He showed by experiments on dogs that this method brings about a large exchange of air, and his view is that more air is exchanged by this than by other methods. Others, however, doubt that, including Professor Keith in his recent lectures.

[Mr. Dent then demonstrated the Howard method on a healthy man, as Howard demonstrated it.]

Howard put a large pillow in the middle of the back for the patient to lie on, the patient being on his back, and his head bent well over the end of it, making practically a right angle with the body. Then he got astride of the patient, placed his hands on the spaces between the ribs, and forcibly compressed the thorax. It was the thoracic type of artificial respiration. According to Howard there was no need to hold forward the tongue, the position of the head in itself being sufficient. Howard grasped the lower ribs, and to some extent, therefore, he made pressure on the abdominal viscera, and pushed them against the diaphragm. At first Schäfer advised that a pad should be put under the thorax, but he had since abandoned that as not only unnecessary but positively injurious. The patient lies on a flat surface, the hands up towards the head and near each other, the face turned to one side, which is an advantage, because you can watch it. You can kneel at the side of the patient, but it is better to be astride him. The hands of the operator are put so that the thumbs are close together, the fingers an inch from the spine, as low down as you can. Our instructions to the police are that the hand be bent back, and that the lower part of the hand be placed just above the iliac crest, so as to be sure that one presses on the body, and not on the pelvis. The rest consists merely in throwing the weight of the body on to the hands so placed, at regular periods of time. Normally expiration comes in part from the natural resiliency of the abdominal wall. In a person apparently drowned, and in a dead person, the abdominal wall will be much less elastic and resilient than it is in a living person. The arms are kept straight, and at each forward movement a pressure of 40 to 60 lb. is made upon the patient's body; more than this is unnecessary, and might even do harm. Schäfer's method was worked out by means of experiments on dogs some years ago, and experiments have been made and repeated on the human subject. The first large body to take this new method up—and great credit is due to them for doing so—was the Life-Saving Society. Mr. Henry, the Secretary of that Society, is a man of great energy, and his boldness in the matter is deserving of the highest praise. That Society adopted it. At about the same time, dissatisfied with the method of Silvester and of Marshall Hall, I was anxious to see if this simpler method of Schäfer could be adopted in the Metropolitan Police.

We have to deal with a good many cases of death, or apparent death, by drowning in the course of a year. As anybody holding any office in a public department is practically a target to be shot at, with no opportunity for shooting back, I thought it better to have another opinion; and the Royal Society of Medicine appointed a Committee to investigate the matter as regards the treatment of the apparently drowned. Their report has been issued, and can be obtained, and it is a very interesting document. They advocated the Schäfer method in preference to others in cases of suspended animation by drowning. Therefore, it was adopted by the Metropolitan Police, and since then I know it has been adopted by many other bodies. I have had repeated demands for this document, and, as a result, it has been sent to various parts of the world. Though this method has been in use only a few months, and there are not very many cases to quote yet and form a judgment upon, I have here a record of all which have been tabulated so far, and enough has been seen to prove that the change in method is a judicious one. Every new method introduced on to the medical stage seems to pass through certain definite phases. All these new methods have their entrances—and but little acquaintance with medicine will convince one that they have their exits, too—and, full of promise, are launched as valuable discoveries. Then comes the critic, or, worse still, the deviser of a rival method, and they boom the question as a new departure. Embittered by an onslaught like this, it may go under altogether. But it may have marked a real advance, or it may perish neglected, having served its purpose. And we need not stop to inquire what, in some cases, that purpose was. If it survives, the originator will often be the next to fall foul of his own progeny; he will point out how greatly he has improved and modified what was uniformly successful when first launched. This has been curiously the case with the methods of artificial respiration and the resuscitation of the apparently drowned. They date back to 1774, when the Royal Humane Society was founded. A fair criticism, and one not without force, on the Schäfer method, has been that the experiment to show the degree of interchange of air which led to its introduction were made on living, healthy individuals, not on individuals who had reduced themselves to a state of apnoea by taking a number of very deep breaths preparatory to the experiment. As has been pointed out, the difference between the apparently drowned person and the living person is great. But Schäfer had experimented on dogs which had been immersed for a greater or less length of time, and in his evidence before the Royal Commission on Vivisection, he said he had been led to the discovery of his method largely by the results of these experiments. My chief object is to put before you the experience already gained by cases actually treated by it. There can be little doubt that it is the simplest method that has yet been devised, and it is certainly the best method to be employed when there is only one person at hand to restore animation. Records of cases show that persons have been, and will continue to be, revived by many other methods. The excellent lectures recently delivered on the subject at the Royal College of Surgeons, and printed in the *Lancet*, give a very good *résumé* of the whole question, from the foundation of the Royal Humane Society. Though I have not a large number of cases, some of them are very interesting.

First, with regard to suspended animation in cases

(a) Delivered at the Polyclinic, Chancery Street, W.C., on Wednesday, June 16th, 1909.

of drowning. There have been several of these cases under treatment. A fair proportion of the cases which the police have to deal with are attempted suicides. Persons still throw themselves off bridges, and it is curious to note how sometimes one bridge, and sometimes another, becomes absolutely fashionable for the purpose for a time. At one time it was Waterloo Bridge; perhaps there was some attraction in the name, or perhaps the little recesses fascinated them. It would be easier to jump from Westminster Bridge, but they do not do it. Sometimes they jump over the Embankment, and a curious point I may mention here with regard to that is, that we have noticed of late years that cases of attempted suicide by throwing themselves over the Embankment in the neighbourhood of Westminster and Waterloo Bridges, which were numerous, have become exceedingly rare. I asked an experienced member of the River Police—who had some interesting but gruesome stories to tell—if he could explain it, and he said he thought it was accounted for by the fact that in the old days, when people jumped over the Embankment they did so in the evening, especially in the winter: there was then little traffic along the Embankment, except a few hopeless wayfarers and wasters at a low ebb, who considered their lives not worth the holding. They did not seem to be moved to the act except at the very last. But every since the introduction of the tram-cars, with the electric light and the movement, these suicides have practically ceased. People probably go down there thinking of doing it, but the sight of the light and movement—especially the light—causes them to turn back. That is an interesting psychological fact. Many of the people who jump from the bridges do not meet their deaths by drowning, but by striking the buttresses. The attempts at suicide more often succeed with men than with women. An officer said that when a man gets into the water he is likely to persist in his intention; but a woman, who is, of course, always varying and mutable, perhaps due to her sex, when she gets into the water will do her best to get out again.

One case was that of a man, æt. 40, who was found in Regent's Park Canal, floating face downwards. It was uncertain how long he had been in the water, but his body was still warm when he was removed. The Schäfer method was applied to this man for half-an-hour, but with no success. I do not know that I ever heard of a system of this sort described before which commenced with a failure. But the method did not answer in this case, possibly because the man was already dead before it was applied. I mention it because we had a post-mortem on this case, and I would that a post-mortem was made on every one of them. Both lungs were found distended to their fullest extent. When the tissue was squeezed, air and water exuded. It was therefore certain that air had been got well into the lungs by this method. As usual, all the abdominal vessels were engorged with blood. An important point is that the Schäfer method not only pushes the viscera up against the diaphragm, but by this movement certainly stimulates the action of the heart, and in this respect it has an advantage over the other methods. Whether in these cases we should be too instant in emptying the veins of the portal system and the abdominal viscera, is a moot point. If you do, you are overfilling what is already too full. In the instructions given, great stress is laid on not wasting any time in removing or loosening the clothing. Schäfer was anxious that the movements of artificial respiration should be commenced instantly, but I think he carried the matter a little too far, and that some loosening of the clothes about the neck and elsewhere, particularly in the case of women, is desirable. The police have always to summon a medical man, and in this case the medical man gave his opinion to me that the thick clothing the patient had on appeared to have interfered with the movements and hampered sufficient pressure. I pointed out that the pressure should be gentle, because the viscera are engorged with blood, and after immersion the liver is very friable, and there is some risk of its rupturing. This accident has happened in dogs, but has not yet, I think, been recorded in human beings. But we do not get enough post-mortems. It is only likely to appear when methods such as the Howard method, or the

old-fashioned method of rolling a person to and fro on a barrel are practised. There is the question of interference with the descent of the viscera by tight clothing about the waist, or over the upper abdominal region, particularly a belt, or thick trousers, or corsets. These may interfere materially with the proper expansion of the epigastrium and the descent of the viscera. If an assistant is at hand it is certain he should devote his attention to loosening the clothing.

Another failure was in the case of a man, æt. 64, who jumped from a ferry steamer into the Thames, and was rescued by a boat-hook. He was said to have been immersed five minutes. The weather was bitterly cold at the time, and no doubt this, coupled with the man's age, rendered the case very unfavourable. Schäfer's method was practised in the boat while it was being rowed to the riverside station. This method is much more easily applied than is the Silvester method, and more so than the Marshall Hall.

Another case is that of a man, æt. 27, who threw himself into the Thames off Greenwich. He was rescued in an unconscious condition after only a few minutes' immersion, and was restored by the Schäfer method after ten minutes' work on the foreshore. That was the first successful case there was. The medical man came promptly in this case, and gave the fairly safe opinion that the man was suffering from the effects of immersion. It has been suggested to me by one or two divisional surgeons that the Schäfer method is more adapted for men than women, but I do not agree with that. The pressure should be gradual and gentle, the weight of the body being quietly thrown on to the patient's back. If this is done, the entrance and expulsion of air will be found equally satisfactory in both sexes, and will be as suitable for the stout as for the emaciated. Mr. Henry, of the Life-Saving Society, is convinced that, if you immerse a stout person and an emaciated person under the same conditions, and for the same length of time, the stout person has a decidedly worse chance than the thin. One assumes that neither has prepared himself or herself for immersion by taking a series of very deep breaths. There is an objection which has been urged against the Schäfer method, and it is one which I heard Silvester make a good deal of just before his death, that the astride position over the person is indecorous. But where it is a question of life or death I do not think that matters much.

Another case occurred at Portsmouth, and animation was successfully restored. The Silvester method was adopted for a time, but there was no return of breathing. Then came a police sergeant primed with these instructions, set to work by the Schäfer method, and restored animation. It is easy to claim that as a definite success for the Schäfer method, but I have no wish to do so, because the other method could not be said to have failed. The experience of the police themselves is altogether favourable to the Schäfer method.

The Committee of the Royal Society of Medicine were only asked: Was this the best method to apply in cases of suspended animation from drowning? I may, therefore, say a word or two about cases other than drowning in which this method has been employed. There was a case of unconsciousness, where the sufferer was overpowered by heat. The usual methods were employed, without result; there were no respiratory movements at all. Condition of heart not stated. The Schäfer method was employed for a few minutes, and animation was restored, and the doctor considered it proved of signal value. But he placed a large pad underneath the thorax, which is little more than the Howard method reversed.

Another case was that of coal-gas poisoning in a man, æt. 84, and a woman, æt. 77. The man's body was cold, and there was marked *rigor mortis*. In the woman the *rigor mortis* was confined to the muscles of the neck and lower jaw—possibly the muscles most used. The woman's body was warm, but she had got under the bed-clothes. There the Schäfer method was applied 1½ hours. It was noted that sufficient air could be pressed out to extinguish a lighted match. The teeth were closed, and the air got in easily by

the nose, showing that the position of the head is sufficient to make the tongue drop forward and open the glottis.

There was a suicide by attempted strangulation. A constable—an ambulance man—was told that a man was lying unconscious, with a flannel waist-belt tied round him, and the Schäfer method restored him in ten minutes. In such cases it is seldom that patients are not dead before help is called.

A boy, æt. 9, was climbing on to a cart, and the shaft apparently gave way and struck him a severe blow across the neck. The breathing stopped, and when help arrived the face was the colour of that of an asphyxiated person. The Schäfer method was adopted, and oxygen was applied by the medical man. Probably there was extensive injury to the pneumo-gastric and cardiac nerves in the neck. He recovered, but was very ill for a time, and was taken to a hospital.

In another case a woman attempted to drown two small children, æt. 3 and 4. The Silvester method was adopted, and it was stated that the medical man who was called in said it should not be applied in the case of children.

There was another case, where a constable was called a few days ago to a burning house, and found there was much smoke. He broke his way into the door and got upstairs, but was driven back by the volume of smoke which was pouring down. He understood there were children in the house—the parents, I think, had escaped. Being overcome by the smoke, he made his way down, got outside, took two or three deep breaths, wetted a handkerchief, put it over his mouth, and brought back a child, 3 years of age. Equal credit is due to a man who, seeing what was going on, did precisely the same thing, and he fetched out a child, 1 year 10 months old. They were both completely unconscious, overcome by the smoke, and in both cases the Schäfer method was applied. It is peculiarly suitable to children. In one case the method was pursued 30 minutes, and in the other case 40 minutes before breathing recommenced. Of course, the pressure needs to be proportionately gentle for children. The rescue was a combination of pluck, promptness, and skill, which deserve all praise.

To sum up, my experience so far shows it is applicable in every sort of case: to the young and the old, to both sexes, and the method fulfils all that Professor Schäfer claims for it.

NOTE.—A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by Professor Henri Huchard, M.D., Physician to the Paris Hospitals. Subject: "Digitalis and Digitaline: with Special Reference to their Uses and Modes of Administration."

## ORIGINAL PAPERS.

### A CLINICAL INQUIRY INTO THE USE OF "VACCA" MILK FOR BOTTLE-FED INFANTS AND FOR SICK CHILDREN.

By WILLIAM EWART, M.D. Cantab., F.R.C.P. Lond.

Consulting Physician to St. George's Hospital, and to the Belgrave Hospital for Children.

IN COLLABORATION WITH

EDITH M. GUEST, M.B., B.S.,

Late House-Surgeon to the Belgrave Hospital.

THE publication of this inquiry, to which reference was made in the *Lancet*, Vol. ii., 1908, p. 1742, was unavoidably delayed, but has not ceased to be opportune, if, as estimated by Dr. Arthur Newsholme in his recent work on "The Prevention of Tuberculosis," probably 20 per cent., of the milk supplied to large towns still contains living bacilli. In the City the tubercle-infected milk supply seems to have now reached a higher percentage than ever recorded before. And in a recent monthly report by Dr. Collingridge, Medical Officer of Health for the City of London, the following conclusions are drawn from Dr. Klein's

examination of 32 samples from the home counties: "15 per cent. had an appreciable amount of dirt; 40 per cent. had pathogenic bacteria; 43.5 could be classed as pure."

"Of the samples which had pathogenic bacteria, 12.5 per cent. produced in guinea-pigs definite tuberculosis with the typical tubercle bacilli (this being a jump from 7.7 per cent., the previous record). Of a number of guinea-pigs inoculated with the sediment from the samples one died with severe inflammation of the lungs and another with extensive pseudo-tuberculosis."

The bearing of these conditions upon the prevalence of infantile tuberculosis, and the duty not to allow any considerations of secondary importance to withhold the trial of a remedy for the evil both efficient and capable of immediate application, are the reasons which originally prompted this inquiry and which now justify its publication.

#### I.—SOME SPECIAL FEATURES OF "VACCA" MILK.

Any sound, rich milk, free from all adulteration, and which could be preserved indefinitely in the sterile state without losing its quality and freshness of taste, and which could be used in any season or climate, must claim attention in view of our persistent failure to provide for the infants of the poor an unvarying supply of absolutely reliable sterile milk of high nutritious value. The "Vacca" milk has proved to be of that description; and if the supply could be made as unlimited as the demand, since the local distribution in our great cities would be quite a simple matter, there would remain only to ascertain whether the milk bears out its claims in practice, and is found to be a satisfactory food for bottle-fed infants.

Strangely, though the verdict has been universally favourable as regards its general consumption, and in particular as regards its use on steamships and in the tropics (which seem to have hitherto absorbed the greater part of the supply), its clinical uses have not been much studied, and its nursery value does not seem to have been thought of until Dr. Bilderbeck Gommess brought the facts to my notice.

*As an Invalid's Milk.*—It had already been conclusively established by the investigations of Dr. Klein (a) and of eminent foreign bacteriologists, that the milk supplied under the name of "Vacca" was absolutely free from bacteria, and also from the addition of any preservatives; and yet capable of being kept indefinitely, ready for use at any time or in any climate, and without losing its flavour of fresh milk.

The writer's clinical experience of its use in adults had borne out the report that in spite of its rich quality it is singularly light of digestion and therefore suitable for invalids and particularly for exclusive milk diet cases, and also for cases of typhoid that is, during the stage of convalescence; for the Prideaux-Selby Treatment by Whey during the fever itself has been adopted by him, and by many others since the publication of Dr. Prideaux-Selby's remarkable observations. (b)

*As an Infant's Milk.*—As regards infants, the evidence was still wanting as to whether it might prove a dependable substitute for mother's milk, a point of great importance, seeing that any infants exclusively fed on this milk would be absolutely protected against the risk of any milk-borne infection. The facts carefully observed and recorded at the Belgrave Hospital for Children are a first instalment of that evidence, pending any further trials which it would be desirable to institute elsewhere on larger numbers.

There is no published account of the method adopted in the preparation and bottling; but the facts available and the claims advanced in favour of this milk are set forth in the pamphlet, entitled "The Vacca Company, Limited, Amsterdam, Holland—Milk sterilised without loss of freshness—Milk preserved indefinitely without the addition of any kind of preservative."

(a) *The Lancet*, Vol. i., 1902, p. 875.

(b) "Milk or Whey in Enteric Fever?" *The Lancet*, 1901. Vol. ii., p. 1182.

I. The vacuum in the neck of each bottle, recognised by the "water-hammer" test of succussion before opening, is a handy proof that no gaseous fermentation has occurred, and that the milk is presumably as sound as when it was bottled.

II. The absolute sterility of the milk was attested after searching examination by Dr. Klein, who also testified that:

III. The milk contains no germicides, as it proves to be an excellent medium for the cultures of bacillus coli and other micro-organisms. In the words of Dr. Klein's report: (a) "It follows that the milk is sterile, that it has no flavour of having been boiled, and that it contains no added substance that would inhibit the growth of microbes intentionally added. It must be clear from these results that the hitherto unsolved problem of having milk sterilised without boiling, and to retain the milk sterile without any preservative has, in these milk samples, been satisfactorily solved."

IV. It cannot, therefore, be allowed to stand open much longer than ordinary milk without undergoing decomposition. In other respects, too, the milk behaves like ordinary fresh milk. But it is found, and this is perhaps not unconnected with its special lightness of digestion, that the cream does not rise on standing, and that clotting does not occur so readily on the addition of rennet or other coagulants.

V. Documentary evidence as to the freshness of its taste is supplied in the following note, quoted from the same analytical report (*Lancet*, Vol. i., p. 675, 1902): "The condition of all the samples was satisfactory; the most remarkable feature being the entire absence of 'boiled' flavour. We could find no preservatives. The milk is retailed at 3d. per litre (that is, nearly an English quart). It is the first time that we have met with a sterilised milk giving absolutely no evidence to the taste of having undergone a sterilising process."

VI. The sterilising process is in itself a guarantee, and provides for freedom from infection; but in addition, the greatest care is stated to be used, under constant veterinary supervision, to exclude pollution in the milking sheds. The milk is originally clean milk.

VII. It is also stated that none but the absolutely fresh milk from the select herds is passed for treatment, and that it is bottled within a very short time after being drawn.

VIII. Lastly, the important statement should be mentioned that, as uniformity of excellence is the great aim, not only are the cows submitted to the closest scrutiny as to their milk-fitness, but no milk is bottled during the periods when change in feeding, &c., causes uncertainty in its quality. No "Vacca" milk is produced during the months of April and October.

Three main facts would seem to be established:—(1) That the milk is a good, rich, fresh-tasting milk, absolutely sterile and unadulterated; (2) that it can be preserved indefinitely; and (3) that each bottle can be satisfactorily tested as to the persistence of a vacuum by a sharp tap on the stopper before opening.

The distribution of a supply of good milk to any region and in quantities sufficient for any reasonable period of time is thus rendered possible. And this would imply that a practical solution is at hand for the problem how to ensure for the infants of the poor a never-failing and reliable supply. The all important question remains: Does it fulfil the clinical requirement for infants when put to the clinical test?

#### II.—THE CLINICAL OBSERVATIONS.

A first group of cases was studied in the winter and spring of 1908. The second and larger group in collaboration with Miss Edith Guest, M.B., B.S., during the period October, 1908, to March, 1909.

The points for investigation were the following questions:—

(a) Whether this milk was (1) acceptable to infants; and (2) easily digested.

(b) Whether it proved nutritious.

(c) Whether it was free from the drawbacks which

have sometimes attended the exclusive use of sterilised and pasteurised milk, and particularly from the production of any rachitic or scorbutic symptoms; and (d) Whether it was suitable in the various infantile disorders.

The answers to these questions are contained in the facts recorded in connection with the following cases:—

*Undiluted "Vacca" Feeding.*—It will be seen from the notes that several other infants, much younger than the following, were tried on undiluted "Vacca." Case 319, æt. 1 year 10 months; wasting; "Vacca," 10 oz. daily for 7 days; stools well digested, and the condition excellent. Case 275, æt. 1 year 9 months; bronchitis and rickets; "Vacca," 3 oz. three-hourly for 7 days; subsequently diluted with  $\frac{1}{2}$  water; the curds became very small, and the patient was discharged much improved. Case 335, æt. 2 years; bronchitis; did well; stools well digested. Case 259, æt. 1 year 3 months; "Vacca," 4 oz. three-hourly for 4 days; also bread and butter and milk pudding; some vomiting and curds in the stools resulted; "Vacca" was reduced to 3 oz.; no vomiting; the curds very small, and the stools no longer offensive; this was a good test case showing the digestibility of the milk in conditions of mixed feeding. Case 257, æt. 11 months; gastro-enteritis; "Vacca," 3 oz. three-hourly, increased in two days to 4 oz., and two days later to 5 oz.; two days later small curds began to be passed; the "Vacca" was next diluted with water ( $1\frac{1}{2}$  oz. water to the 5 oz.), the curds then disappearing. This was a good test case for the digestibility of the undiluted milk in large feeds.

*Mixed Feeding with "Vacca."*—Some infants of 2 years and under, suffering from broncho-pneumonia, gastro-enteritis, rickets, or wasting, were fed on bread and butter and milk pudding in addition. Far from the "Vacca" disagreeing, they all did well. Cases 363, æt. 6 months; 317, æt. 1 year 1 month; 259, æt. 1 year 3 months; 322, æt. 1 year 4 months; 275 and 284, æt. 1 year 9 months; 319, æt. 1 year 10 months 340 and 355, æt. 2 years.

*Exclusive Feeding with "Vacca" for  $3\frac{1}{2}$  months.*—Case 261, J.E., admitted September 10th, 1908, æt. 10 weeks, fed on milk and water and Allenbury's; much wasted from diarrhoea for 5 weeks past, was given for 10 days ordinary milk, 1 oz., water 2 oz., two-hourly. He gained weight slowly; but the stools were green and undigested. The following changes were then made: September 20th, peptonised milk, 1 oz.; rice water 2 oz., two-hourly; the stools remained loose and green. 20th: Undiluted "Vacca" 2 oz., two-hourly; the stools became firmer, but remained green. 28th: Vomited, and large curds were passed. Water (2 drs.) added; vomiting ceased till October 4th. Ordinary milk (diluted as before) was substituted for 2 days. 7th: Vomiting has continued. Given peptonised milk, 1 oz., water  $1\frac{1}{2}$  oz., two-hourly. 8th: Has continued to vomit. 9th: Exclusive "Vacca" feeding resumed (with  $\frac{1}{2}$  water). As he vomited again he was given quarter-hourly small feeds of  $\frac{1}{4}$  dr. "Vacca" with  $\frac{1}{4}$  dr. water. The vomiting stopped. 10th: "Vacca," 2 drs., water 2 drs., hourly. 12th: "Vacca," 3 drs., water 3 drs. hourly. Same night 1 oz. of each two-hourly. 13th: Vomited 3 times; ordered hourly feeds again. 17th: two-hourly feeds of 2 oz. (half and half). After 18th, no more vomiting. 20th: An extra  $\frac{1}{2}$  oz. "Vacca" added, although stools still slightly curdy. Gaining weight again. Nov. 3rd:  $2\frac{1}{2}$ -hourly, with  $\frac{1}{2}$  oz. water added. 9th: "Vacca" increased to 2 oz. (with water  $1\frac{1}{2}$  oz.); curds lessening. 20th: Further additions of  $\frac{1}{2}$  oz. "Vacca" and  $\frac{1}{2}$  oz. water, three-hourly; progressing steadily, trying to sit up. December 1st: Open air daily. 7th: "Vacca" 3 oz., water  $2\frac{1}{2}$  oz., three-hourly; small curds occasionally. 17th: Gaining weight, healthy, lively, and content. After sustained progress, discharged on January 7th, having taken no other food but "Vacca" for upwards of  $3\frac{1}{2}$  months, and no drugs except a little castor oil. He had developed no signs of rickets or scurvy. After the interval of indigestion, although the gain in weight

was slow, the gain in strength was steady, and the infant invariably bright and cheerful, being hardly known to have given any sign of pain or distress.

*Simple Constipation and its Consequences on the General Health.*—Two cases (337, æt. 1 year 1 month, and 296, æt. 3 years) were treated; both satisfactory. The first was breast-fed, and cow's milk was said to produce curdy stools and vomit. In the hospital, undiluted "Vacca" (4 oz. three-hourly) was given for two days; the stools less hard but contained small curds. For four days, 2 oz. barley-water added; as the stools were still a little hard, Ol. paraf.,  $\frac{1}{4}$  dr., was given six-hourly for three days, and the stools improved. Six days later, a diet of ordinary milk and barley water, and milk pudding was well taken; the stools (3 or 4 daily) yellow and less hard. Discharged well. No other medicine taken.

*Infantile Gastro-enteritis.*—Case 257, æt. 11 months. Was losing weight on peptonised milk. He gained 9 oz. in 10 days on "Vacca." Discharged well. Case 259, æt. 1 year 3 months. Stools offensive, containing much curd and mucus. Undiluted "Vacca" with a little pudding for 10 days; then "Vacca" 2 oz., barley water 1 oz.; in 3 days the stools were yellow, digested, and not offensive. Discharged well. Case 317, æt. 1 year 7 months. After 3 days on undiluted "Vacca," the stools were yellow, but still showed large curds and mucus. "Vacca" diluted with  $\frac{1}{2}$  water; the stools improved. After 2 weeks, stools nearly normal; no mucus. Discharged, having had no medicine. Case 322, æt. 1 year 3 months. Stools greenish, with mucus and curds. "Vacca" and water, of each 3 oz., three-hourly; in 8 days the stools were yellow and digested. Case 302, æt. 1 year 3 month. Died on fourth day after admission, having vomited persistently, though less sick on "Vacca." Case 311, æt. 3 years 9 months. Blood and mucus in stools. On "Vacca," improved steadily. Discharged well after 8 days.

*Gain in Weight in Cases Admitted for Wasting or Gastro-enteritis.*

Case.	Age.				
337	0 year 11 months.	In 19 days gained	21 oz.		
275	1 " 9 "	" 13 "	" 18 oz.		
319	1 " 10 "	" 7 "	" 10 oz.		
257	0 " 11 "	" 10 "	" 9 oz.		
322	1 " 4 "	" 12 "	" 30 oz.		
317	1 " 7 "	" 32 "	" 34 oz.		
284	1 " 9 "	" 3 "	" 3 oz.		
259	1 " 3 "	" 9 "	" 19 oz.		
285	0 " 9 "	" 26 "	" 22 oz.		
261	0 " 10 "	" 8 weeks "	" 26 oz.		

*Dyspepsia and Wasting from Unsuitable Milk and Foods.*—Case 319, æt. 1 year 10 months. Gained 10 oz. in a week on "Vacca" and milk pudding; was discharged well; stools digested and no longer offensive. Case 345, æt. 5 months; advanced emaciation; "Vacca" 6 oz., water 1 oz. were given, but the abdomen being much distended, whey was substituted; died on 4th day. J. A. M., æt. 2 months; the smaller of twins, breast-fed, had been "wasting" for 4 days with vomiting and diarrhoea; on February 25th, tried the day on undiluted "Vacca" (1½ oz. every 2½ hours); slight vomiting twice, stools as before; on 27th, 6 feeds of undiluted "Vacca," as before; no vomiting, but stools not so good. Not given a dilution of "Vacca," which probably would have agreed, but again diluted peptonised milk. Charles C., æt. 3 months; admitted February 20th, 1908; breast-fed for 2 weeks, afterwards on milk and water; wasting for 6 weeks, vomiting nearly all food after quarter of an hour, with curdy clots; motions constipated, hard and curdy; peptonised milk and water digested fairly well; tried with 4 feeds of undiluted "Vacca" (2 oz., 2½ hourly); not digested perhaps quite so well, but no digestive upset or vomiting. Minnie M., æt. 1 year 6 months; admitted December 23rd, 1907; "spinal caries"; stools "very bad" on milk diet; undiluted "Vacca" milk (5 oz. two-hourly) for 2 days; the motions improved and there was no vomiting.

*Dyspepsia and Dyspnoea.*—W. E., æt. 9 months; admitted March 25th, 1908; severe prostration from

"broncho-pneumonia and dyspnoea"; originally healthy, breast-fed for 3 months, afterwards frail and puny on nursery biscuits and boiled bread and milk. Whilst in hospital (2½ months) cut his 5th and 6th teeth. Frequency and shallowness of breathing, with distended thorax and with rales persisted, although after the first two days the temperature sank below normal, remaining quite low throughout, with rare exceptions. *Treatment:* April 3rd: Still purplish, passive and helpless; to be raised on pillows and to wear the terebene bib and the abdominal elastic belt. 24th: To use the "baby rest." *Diet:* April 21st: Stop previous mixed diet; undiluted "Vacca" only: (5 oz., three-hourly). At first some abdominal distension, which passed away, although the feeds were increased on the 27th to 6 oz. Good progress, but slight loss of weight; a little corn flour allowed again. A good deal of bronchial rale and wheezing still audible on 27th, but active abdominal and thoracic movement had resulted. May 11th: Still wears the belt; good depth and frequency of breath, with abundant air entry, and a coarse and loud respiratory murmur. June 10th: Has been taking solid diet; discharged much improved.

These cases illustrate the toleration for undiluted "Vacca" in delicate infants with irritable mucous membrane.

*Rickets.*—Case 284, æt. 1 year 9 months; bronchitis, marked rickety skeletal changes, but no intestinal disturbance; greatly improved on undiluted "Vacca" for 8 days. Case 241, Florrie V., æt. 2 years 3 months; admitted August 27th, 1908; emaciated, very ill and anæmic; diarrhoea and vomiting for last 12 months; breast-fed for 2½ months, then on cow's milk and barley water; has never walked or talked; pigeon breast, beaded ribs, enlarged epiphyses, but has her 8 incisors; hands, limp and almost powerless; dorso-lumbar curve in sitting; abdomen, large and doughy; liver an inch below costal margin in the mid-clavicular line; 4 stools daily, large, very loose, and pultaceous, with small curds. *Diet:* On admission, ordinary milk. September 15th: Bread and milk and milk pudding; within 14 days, meat or fish, and an egg were allowed; looking less anæmic, but abdomen no less. 22nd: Half-a-pint "Vacca" substituted for ordinary milk, with solids as before. Abdomen became less tense, and patient less helpless and listless. Stools not smaller or fewer, offensive, with some mucus and curds. Abdomen still measuring  $\frac{1}{2}$  in. more than on admission. 27th: Given a mixture of charcoal and paraffin oil. 28th: Stools less bulky and offensive, no curds; colour blackish grey. 29th: Abdomen decreased by  $\frac{1}{2}$  in. October 2nd: As there was no further decrease, the meat, egg, and fish were cut off; the diet to consist of undiluted "Vacca," 1½ pints, dry crust, or thin toast and treacle. 8th: As stools, though less frequent, were still large, loose and curdy, the "Vacca" was diluted with  $\frac{1}{2}$  water. Stools still loose, but curds very small, and patient steadily gaining weight. 20th: Dilution decreased, 5 parts milk to 1 water. November 1st: Egg added; patient began to lose weight and appetite for three weeks, whilst cutting her canines. The stools were still pultaceous, with small curds, but not offensive, and only 3 in 24 hours. 20th: Patient out in open air for several hours daily. 28th: Gravy and potatoes added to diet; steady gain in strength. December 12th: Stools formed and no curds; improvement uninterrupted; looking healthy and vigorous, but is still deficient in walking and talking, though improving in both ways.

*Cases of Acute Affections in which "Vacca" Milk was the Diet.*

A. *Acute Lobar Pneumonia.*—Case 358, æt. 4 years 2 months; took whey for 2 days; then "Vacca" with one-fifth water instead; this was well digested in spite of pyrexia (103°).

B. *Broncho-pneumonia.*—Case 320, æt. 3; undiluted "Vacca" was well taken and well digested. Case 266, æt. 2 years 11 months; "Vacca" taken with light solid food, and well digested. Case 340, æt. 2; it was diluted with  $\frac{1}{2}$  water; the previous

vomiting improved, and the stools became digested. Case 363, æt. 6 months, and Case 354, æt. 3 months. Both took "Vacca" with  $\frac{1}{2}$  of water; there was good progress, and well-digested stools.

C. *Bronchitis*.—Case 298, æt. 2 years 11 months. This patient was vomiting on milk and lime water. Undiluted "Vacca" was given; the vomiting lessened, but continued slightly for 6 days;  $\frac{1}{2}$  water was then added and the vomiting ceased. Case 335, æt. 2 years; undiluted "Vacca" was well taken with light solids; no vomiting. Case 275, æt. 1 year 9 months; the stools were green and curdy; undiluted "Vacca" was given for one week, and the stools improved; a dilution with  $\frac{1}{2}$  water was then substituted, and the stools became more digested. All these patients did well. The diet was "Vacca" exclusively, except in three infants who had some light solids also.

D. *Acute Posterior Basic Meningitis*.—Lily S., æt. 8 months, was admitted March 9th, with constant vomiting. "Vacca" was tried first undiluted, then in dilution, but failed to control the vomiting. Treatment proved unavailing (including lumbar puncture and serum injections). She died on April 9th.

E. *Empyema*.—Horace B., æt. 3 years, admitted January 22nd, 1908. One feed of 7 oz. undiluted "Vacca" was given and agreed.

F. *Double Mitral Disease with Pericarditis*.—Case 301, æt. 6 years 2 months. There was much vomiting, with curds. Under "Vacca," some vomiting continued for 2 weeks, but the curds were less, and the patient was soon discharged in good condition.

G. *Nephritis*.—Case 286, æt. 7 years. This patient had obstinate vomiting with curds on ordinary milk. Undiluted "Vacca" was given; the vomiting decreased and ceased after 6 days and the curds became fewer. Case 305, æt. 2 years. This child was given the dilution 1 to 1, and digested it well.

#### REMARKS.

1. *The Effect upon the Appetite*.—In all the infants the "Vacca" was welcomed from the first, even when the ordinary milk had been taken without relish, and it continued to be taken with great readiness. In one case there was falling off in the appetite both for "Vacca" and for other food, but this occurred in coincidence with the cutting of two canines, and after a prolonged residence in the ward. Open air was prescribed in this case as well as in another infant, whose appetite showed signs of flagging, with excellent results in both instances.

2. *The Effect upon the Digestion* was good in all cases. It may be said of all of them that eventually there was an improvement in the digestion for ordinary milk as a result of a course of "Vacca" milk. A good instance in point is that of No. 337, æt. 11 months, in whom cow's milk caused green and curdy stools. "Vacca" (4 oz.), barley water (2 oz.), three-hourly, were well digested for five days. After this cow's milk (4 oz.), barley water (2 oz.), were well taken and digested.

The chief evidence as to the digestion is to be found in the vomit (if any) and in the stools. The latter showed undoubted improvement. As regards vomiting, putting aside cases such as meningitis, where it was due to cerebral causes, and the terminal stages of fatal gastro-enteritis, vomiting was practically unknown to occur when the rich bottled milk was suitably diluted. In only one instance did vomiting originate under "Vacca" diet. Although only 10 weeks old, and unable to get on with the ordinary milk considerably diluted, this infant succeeded in retaining for 3 days three-hourly feeds of undiluted "Vacca." This tolerance was, however, only temporary; curds increased in the motions, and on the fourth day he vomited the feed. After substitution of ordinary milk, much diluted, and subsequently of peptonised milk, the vomiting did not cease until "Vacca" was again administered in teaspoonful feeds every  $\frac{1}{2}$  hour, gradually returning to the usual intervals and amounts.

#### III.—GENERAL CONCLUSIONS.

I.—The importance of our inquiry lies in the fact

that we are offered advantages hitherto unattainable, viz. :—

(1) A certainty of excellence in quality and of freedom from fermentation. This evidence can be obtained in the case of each bottle by inspection, and by the succussion-test before opening.

(2) The facility for an unfailingly continuous supply of this best quality, day by day, since a sufficient store can be laid in and will keep fresh for any period, so as to guard against every emergency.

(3) The avoidance of the constantly-recurring so-called "accidental" variations in the composition and quality of the highly-promiscuous milk which is retailed, particularly to the poor.

(4) The avoidance (rendered possible for the first time by the stored supply) of the seasonal variations and alimentary variations in the quality of the milk, the milk produced during the less favourable periods being excluded. Under our ordinary system of daily supply, this unevenness of quality is, of course, unavoidable, even in the case of first-class herds. With this milk, as an almost identical quality can be procured indefinitely, if an infant be well suited by the trial sample, the bottle feeding question would be solved for that infant. And if practically all infants were found to be suited, then the infant feeding problem itself would have found its solution.

II.—*The Clinical Results*. (1) Individual toleration for the "Vacca" milk appears to be the individual rule in infants.

(2) Its acceptability is also the rule with infants.

(3) Its digestibility is proved by the following facts to be greater than that of the ordinary milk.

(4) Its substitution sometimes suffices, without any other help, to cure the dyspepsia due to ordinary milk.

(5) It can be administered *neat* to some infants without detriment; but in most of them a slight dilution will suffice where ordinary milk had to be much further diluted.

(6) The improvement in the character of the stools is a proof of its better digestion.

(7) Its exclusive administration to infants for prolonged periods, so far as it has been tried, has not led to any symptoms suggestive of scurvy or of rickets, nor to any other morbid symptoms.

(8) Infants fed upon it exclusively have improved in health, in strength, and in weight.

(9) Increase in weight has perhaps been less considerable than the increasing strength—possibly, in part, by reason of the greater muscular activity evinced.

(10) Although the "Vacca" fed infants have not run to fat their general nutrition has been very good.

(11) In conclusion: As the results of our clinical observations have been highly encouraging, it is most desirable that the inquiry should be taken up by other observers on a much larger scale, to test more thoroughly the question as to the genuineness of the claim of this milk to be the much needed *reliable infants milk*, particularly for the poor.

## SPINAL ANÆSTHESIA IN SURGERY. (a)

By VIVIAN ORR, M.B., B.S.,

Anæsthetist to Westminster Hospital.

THE induction of anæsthesia by the intra-spinal injection of certain drugs, of which cocaine is the pioneer and type, is a comparatively recent event, and one which has naturally excited a general interest amongst our profession and the public.

The surgeon is delighted with the ideal conditions for operating which the muscular relaxation affords, and he vividly remembers his last case of prostatectomy in a stuffy theatre on an old bronchitic patient with calcareous arteries and rigid recti. Add to this that the prostate was small, hard and adherent, and that the breathing made the

(a) Paper read before the Annual Meeting of the Chelsea Clinical Society, May 16th, 1909.

anæsthetist look careworn. Is it then to be wondered at if the surgeon is predisposed to favour the innovation which remedies all this? The layman, too, reads the "ha'penny press," and naturally, when anything operable crops up in his family, such as a baby arriving or a tooth beginning to ache, asks for some of that new "Daily Something" stuff that "puts you to sleep without taking away your senses"; while the early impression of the anæsthetist is that the newcomer is analogous to the taxicab come to oust the horse-drawn vehicle from the streets, and he thinks of eliciting the sympathies of a great ex-politician or the editor of a "Daily Something."

It is proposed to discuss these standpoints of surgeon, patient and anæsthetist, and, with the assistance of the members present, to try and arrive at the correct attitude to be taken up in relation to spinal injections in surgery. It is impossible to indicate in a short paper all the points in a subject like spinal anæsthesia, which now has an immense literature. The use of lumbar puncture to relieve the pressure in hydrocephalus, or for therapeutic or diagnostic purposes, is outside the scope of the paper, but there is a close connection between all these practices in details of *technique*, symptoms and dangers.

Spinal anæsthesia has been described as a link between local and general anæsthesia. It goes a step farther than local anæsthesia, and perhaps you will agree that up to now it does not attain to the giddy heights of skilfully-conducted general anæsthesia. That it is going to make a niche for itself in the anæsthetist's already bulging bag, I have every confidence. The fact that several substances have been employed, and are still employed, and that each has its warm advocates, that the method of solution and injection, that the posture of the patient, and even the after-treatment, are matters on which different authorities differ, is significant. This state of instability and uncertainty is tantamount to a confession of ignorance and an admission that the stage of experiment and trial has not been yet left behind.

Cocaine was the first drug used for this work, and it is interesting, historically, to learn that an American was the first man to experiment with it. Leonard Corning, in 1885, injected cocaine into the spinal cord, and suggested its use for intraspinal anæsthesia in surgery. But, as in the case of so many great discoveries, their true value is not generally recognised for years, and it was only in 1899 that Tuffier, in Paris, and Bier, in Germany, made practical use of Corning's suggestion. Tuffier first injected cocaine into the lumbar sac to relieve the pain of an osteo-sarcoma of the pelvis, and the success of this induced him to make use of the method for surgical operations.

Bier had the pluck to have himself injected with cocaine, and suffered from a bad headache as a result, and even as late as 1901 he described the treatment as being in its infancy, its *technique* faulty and dangerous, and the effects disagreeable and not to be recommended.

Next came the introduction of synthetic drugs, which aimed at eliminating the toxic factors in cocaine, while maintaining or increasing its anæsthetic value.

The *desiderata* in a synthetic cocaine are, in addition, solubility in water, stability and sterilisability; harmlessness to the tissues, no irritation, inflammation or necrosis, and rapid action.

Experiments and clinical work have eliminated many drugs as inefficient or dangerous, while retaining those known as stovaine, tropacocain and novocain; and a remarkable paper by Chaput, of

Paris, extols the virtues of a mixture of stovaine with cocaine, to which I will refer again.

The addition of adrenal preparations to increase the anæsthetic action has been found dangerous and is hardly, if ever, employed now.

The method of solution and the dosage is evidently not yet generally agreed upon.

That the medium should be isotonic with the cerebro-spinal fluid, and that the specific gravity of the solution should be greater than that of the cerebro-spinal fluid, are points on which emphasis is laid in some quarters, the intention being to have a rapid absorption over a localised area of nerve roots. The actual amount of actual fluid injected is an important factor in regulating the height of the anæsthesia, apart from the amount of drug, but posture and movement must have some influence in this respect, in addition to the dose of the drug employed.

As usually given, the dose, from 0.04 to 0.06 grm., is enclosed, ready sterilised for injection, in a glass ampoule dissolved in an unirritating fluid. If these ampoules are obtained from a reliable source they are a great convenience. One practical point, though, is, that the contained dose should be clearly indicated. Neglect of this has led to a fatal result.

The syringe must be sterilisable, and the needle and cannula strong and long enough to enter the sub-arachnoid space in a fat muscular adult 3 inches to 4 inches, that is, well over the average depth, which is 2½ inches to 3 inches. The patient's skin must be sterilised with the usual fluids, and kept covered as far as possible during the puncture and after.

The puncture is usually made in the sitting posture, with the patient's back arched as much as possible so as to show up the landmarks and widen the interval between the spines and laminæ. The lateral posture is the other alternative; it is more difficult to enter the canal in this position, but the condition of the patient often renders it necessary. Some opinions as to the value of spraying the site of puncture with ethyl chloride I should like to have. Having had a recent experience of its effect on a poisoned finger, I can only think that it is adding insult to injury.

But a most important factor in the whole conduct of these cases is the obtaining the confidence of the patient. A man must be told beforehand what he has to expect, or he will suffer himself and give trouble to the surgeon. In a hospital where many cases are being done there is very little trouble in this respect. The patients tell one another, and it is the exception for a patient who has once had general and once spinal anæsthesia not to greatly prefer the latter. It requires some little experience to tap the cerebro-spinal fluid with accuracy and certainty, and every now and then there comes a spine that refuses to be disturbed; no amount of prodding will induce the fluid to flow in drops or steady stream through the cannula. Then is the time for the anæsthetist—like cabby picking up the passenger from the silent, motionless motor—then is his time. There are other factors of uncertainty, as to extent and duration of the anæsthesia, even in the most skilled hands, which have made the use of a general anæsthetic compulsory—bent and broken needles, blood, etc. But in a typical case, having allowed 5-10 c.c. of the fluid to flow from the cannula, to obviate risk of headache, attach the syringe and inject the fluid slowly. Remove the needle, and, covering the puncture area in case a second injection has to be made, place the patient on his back with head and hips raised. In most cases the puncture is made in the second or third lumbar interspace. Where the first is chosen, care

must be taken not to wound the cord. Even in those cases where high anæsthesia of the upper extremity and head is aimed at, the site of injection remains in the lumbar region.

**Onset.**—The onset of anæsthesia is rapid—in 1½ to 2 minutes. There is loss of sensation to pain in the perinæum and scrotum, and some heaviness in the limbs: rapid loss of knee-jerks. Tactile, thermal and localising sensations are at first retained. Within the second minute the Achilles tendon reflex disappears, and rapidly the anæsthesia spreads to the umbilicus, rib margin or transverse nipple line. In from 5 to 7 minutes there is muscular as well as sensory paralysis, though the power of telling the position of the limbs may be but little affected. Of the deeper structures, those innervated by the sacral nerve roots are analgesic, but it is more unusual to get a good anæsthesia of the scrotum and spermatic cord, which are supplied by the first lumbar segment; and the same holds for the peritoneum, with its vagal, phrenic and sympathetic supplies. Pain and discomfort are common in those cases where the spermatic cord or mesenteries are under manipulation.

The duration varies largely, and herein lies one of the disadvantages of the method, but, as a rule, an available anæsthesia of from 45 to 60 minutes can be counted on.

The return of sensation is more slow than the disappearance, and takes place in the reverse order; first motion, then sensation, and then reflex action reappearing (time, 1½ to 3 hours after injection).

In the majority of cases the pulse and respiration are not affected as the anæsthesia is asserting itself, but there have been several cases in my experience which have shown symptoms of collapse, pallor, feeble, rapid pulse, cold sweats, and great mental anxiety, this occurring about 8 to 10 minutes after the injection and soon after the commencement of the operation. The explanation may be a psychic or toxic one, or the relaxation of the abdominal muscles may permit of so much blood being retained in the splanchnic area as to induce a condition of cerebral anæmia.

Whatever the cause, the condition is only temporary and relieved by brandy or caffeine, but in an already enfeebled patient this temporary collapsed condition might prove the last straw. The Trendelenburg position is stated to relieve this anæmia, also oxygen. The preliminary use of a sedative, such as morphia and scopolamine, is strongly advocated by some in nervous patients (e.g., morphia, ¼ grain given half an hour before the operation), and it is a routine practice either to bandage the patient's eyes or have a screen placed so that he cannot see the operation. Some cotton-wool in the ears, too, often saves the patient from hearing an incautious or peculiarly emphatic expression. Some patients smoke during the operation, and it is best to keep their attention fixed away from the scene of bloodshed. It has been my lot to while away some lengthy hours in a futile endeavour to interest a labourer on current topics; even a quarter of an hour seems to them interminable under the circumstances. It is at times like these that one almost wishes to be a surgeon, or has a lurking hope that the subject will begin to groan and give poor cabby a chance.

It is best, when beginning the operation, to avoid asking the patient if he feels anything. Test the anæsthesia with a pair of forceps, but do not risk losing his confidence.

The contra-indications to the employment of spinal anæsthesia, as enumerated by Chaput, are: (1) In arterio-sclerosis and advanced cardiac disease; (2) in old and feeble patients over 65 liable to

syncope after its use, and apoplexy; (3) in cachectic states, grave anæmias, infective states, albuminuria, diabetes, syphilis and diseases of the nervous system. But he believes that general anæsthesia in these conditions is still more dangerous.

Septic or diseased conditions of the skin over the lumbar spines have prevented lumbar puncture, while in some malformed spines and osteoarthritic cases it has been found impossible to enter the sac. In long and complicated operations, where the conditions to be dealt with are not known beforehand, there is risk of the analgesia proving inefficient.

Barker reports two fatal cases occurring in patients suffering from abdominal malignant disease involving much manipulation of viscera, but whether the anæsthetic agent was responsible for the disasters or not is, in such grave cases, open to doubt. The opinion of many authorities seems to be that lumbar anæsthesia should be limited to operations below the umbilicus.

Chaput, of Paris, wrote an interesting and striking paper last year, giving the results of a series of cases in which he operated on the thorax, upper extremities and neck. He used a mixture of stovaine and cocaine, and gave a preliminary injection of morphia and scopolamine hypodermically. I was sufficiently impressed with his paper to go and see him personally last week, only to find that, on further trial, he had abandoned this method, and had since October last adopted novocaine with enthusiasm and success, while drawing a line round the body at the umbilicus and confining his operations to the regions below.

I may add that in the cases which I saw him do—a resection of a piece of the tenth rib and a fixation of a retained testis—the patients, both nervous men, seemed to suffer considerable pain, and both exhibited symptoms of collapse.

On the other hand, one of Mr. McGavin's cases at Greenwich exemplifies the value of this method. The patient was a seaman who had an aortic aneurysm, and the operation was for a recurrent popliteal aneurysm, which was dissected out. During the hour that the procedure lasted the patient was quite unaffected, talking and smoking unconcernedly, and his subsequent history was quite uneventful.

In cases of bad compound fractures of the lower limbs it is remarkable how the shock of the injury is alleviated by the cessation of stimuli passing up the cord, as is the subsequent shock of the manipulations or amputation.

Many successful operations for prostatectomy have been performed, the relaxation of the recti allowing of unimpeded access to the gland, and, in addition, since these patients are often subjects of heart, lung and kidney disease, the advantages of spinal over general anæsthesia are considerable.

For operations on the lower limbs, scrotum, perinæum and inguinal regions, where local anæsthesia is not available, spinal anæsthesia offers an alternative to general anæsthesia.

The choice will be influenced by several considerations. Many patients have such a dread of a complete loss of consciousness that they will cagerly grasp any alternative offered. And in favour of spinal against general anæsthesia can be urged a comparative absence of the unpleasant after-effects of ether and chloroform, the lessened risk in cases of grave visceral disease, the impossibility of the occurrence of the late toxic effects of ether and chloroform, the abolition of shock, and the relaxation of the muscular system. While, as counsel for general anæsthesia, one can urge the

advantage of the absence of the psychic effect of the patient's consciousness both on himself and the surgeon, the uncertainty of spinal anæsthesia, both in point of duration, adequacy and extent, and, finally, the absence of any risk of a septic meningitis or a paresis or paralysis of temporary or permanent character, vomiting and headache. As I mentioned at the beginning of this paper, the amount of work done, and being done, in connection with my subject is very large, and it is being done all over the world under all sorts of conditions—in the Services and the back-blocks, as well as in the great city hospitals—and many a man working single-handed has to thank spinal anæsthesia for enabling him to perform operations and save lives, which under the old conditions would have been beyond his powers, or, at any rate, have taxed them to the utmost.

But at present, in my opinion, the statistics are not complete enough, nor are the indications or *technique* sufficiently clearly defined to enable us to assign to spinal anæsthesia its proper place in surgery.

## OPERATING THEATRES.

### CHILDREN'S HOSPITAL, GREAT ORMOND STREET.

OPERATION FOR ACUTE ABDOMINAL SYMPTOMS DUE TO A CASEOUS GLAND IN THE MESENTERY.—MR. EDRED M. CORNER operated on a girl, æt. 11, who had been admitted with a history of three days' illness, accompanied by sickness, abdominal pain, and inactivity of the bowels. On admission the temperature was normal, and the pulse about 120. On examination the abdomen did not move well on respiration; it was rigid, tender all over to both palpation and percussion. Rectal examination revealed general tenderness. In the great majority of cases, Mr. Corner said, a child presenting such symptoms is suffering from appendicitis. The next most common cause is associated with the presence of Meckel's diverticulum. In this case, he pointed out, there is a combination of peritonitis and intestinal obstruction due to mechanical causes. There is a somewhat similar condition when appendicitis is present, the intestinal obstruction being caused by paralysis of segments of the bowel. The presence of Meckel's diverticulum in cases where it gives rise to clinical symptoms almost always presents some abnormality of the umbilicus; this may be found in a protruding, retracted, or displaced umbilical scar. No such abnormality was present in this particular case, so that it was thought that Meckel's diverticulum was not present. The absence of pyrexia, the irregularity of the sickness, and the inactivity of the bowels also suggested that appendicitis was not present.

An enema was administered by means of a tube and a funnel, and returned with no result either in *fæces* or *flatus*. Hence it was apparent that some intestinal obstruction was present. Under such circumstances, the abdomen was opened at once, the incision being made through the right rectus. The fibres of the rectus muscle were separated, and the abdomen opened in the ordinary way. The cæcum was delivered, and the appendix found to be normal. No greatly distended or collapsed bowel was seen, such as would indicate the presence of a formation causing intestinal obstruction, but in the mesentery of the small intestine a mass was discovered the size of a billiard ball and soft in consistence. Gauze was packed around so as to shut off the peritoneal cavity in the vicinity of the mass in the mesentery from the rest of the peritoneum. The mesenteric mass was then raised to the surface of the abdomen; in doing this the mass ruptured, and pulsatous material escaped. All such material was carefully wiped away and the rent enlarged in the direction of the axis of the mesentery. The interior of the mass was then thoroughly but gently curetted so as to avoid any risk of injury to the mesenteric vein. Mr. Corner remarked that he had had the importance of this thrust upon him recently by losing a somewhat similar case

from secondary hæmorrhage into the cavity of a tuberculous abscess a few days after operation, the hæmorrhage taking place from a mesenteric vein into the abscess cavity and bursting between the stitches, spread into the general peritoneal cavity, necessitating a second operation, from the shock of which the patient died. After having carefully curetted the interior of the mesenteric abscess, Mr. Corner sutured the walls in such a manner as to fold them and largely obliterate the cavity of the abscess when the stitches were tied. Silk stitches on curved round needles were used, and care was taken not to injure any of the branches of the mesenteric vessels. The region was then thoroughly doused with sterilised saline solution, the plugs removed, and the abdomen closed without drainage in the ordinary way.

Mr. Corner now said that he had operated on quite a dozen similar cases. They were like each other in presenting a fairly healthy child with an abdominal tumour which had been discovered by accident, and which was smooth and lobulated in outline, and freely movable. Such tumours, it was found, were commonly regarded as being a faecal accumulation and treated accordingly without any effect on the tumour. It is needless to point out, he thought, that such delay militates against the chance surgery has in obtaining good results, for, next to tuberculosis of the bronchial glands, tuberculosis of the mesenteric glands is the most common cause of general tuberculosis. The presence of this abdominal tumour is at times associated with some looseness of the bowels, with blood and mucus in the stools, or, instead of this being present, there may be a history of its occurrence previously. Cases of tuberculosis of the mesenteric glands, with a palpable abdominal tumour, should be treated by operation without delay. Mr. Corner added that he had lost two cases, one from tuberculous meningitis a few days after operation, the disease really being present before the operation; and the second case from hæmorrhage from a mesenteric vein a few days after operation, as he had mentioned above. Some of these cases had been followed for five to six years after operation, and it had been found that great physical improvement followed in almost every one.

The patient made an uninterrupted recovery, and left the hospital after a fortnight.

## TRANSACTIONS OF SOCIETIES.

### CHELSEA CLINICAL SOCIETY.

ANNUAL MEETING, HELD MAY 16TH, 1909.

The President, Mr. A. F. PENNY, F.R.C.S.I., in the Chair.

MR. LEONARD A. BIDWELL, F.R.C.S., was elected President for the ensuing session.

Dr. VIVIAN ORR read a paper on

#### SPINAL ANÆSTHESIA IN SURGERY,

which will be found on page 12 of the present issue.

Mr. J. D. MORTIMER agreed that at present the method should be reserved for cases in which a general anæsthetic was clearly inadvisable. It answered very well in suprapubic prostatectomy, there being absence of disturbance on distending the bladder, of muscular spasm, and of shock. He was using 5 c.c. of a 2 per cent. solution of novocain and mannitol. He did not freeze the skin, but used the point of a knife for its puncture. Much attention to details was needed for success.

Dr. HILLIARD gave some particulars about the *technique* of the operation, and insisted on the importance of abstracting some of the cerebro-spinal fluid. He also spoke of the presence of shock in certain cases.

Mr. J. HOWELL EVANS also spoke of shock and collapse, and considered it important to ascertain whether these symptoms were due to over-manipulation by the surgeon, or to an overdose by the anæsthetist.

Dr. DRYSDALE inquired as to the results when cocaine alone was employed, and Dr. ROBINSON asked for information as to the mortality statistics.

Dr. ORR replied.

## CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS  
ABROAD.

## FRANCE.

Paris, July 4th, 1909.

## CONSUMPTION—TREATMENT OF SYMPTOMS.

FOR the different complications of pulmonary phthisis, the medical attendant, says Prof. Robin, should have a large therapeutical arsenal.

*Cough.*—The cough in consumptive patients may be due to multiple causes but, generally speaking, the patient should not cough except to expectorate. He should endeavour to control his cough, as resistance to the desire of coughing is one of the best means of diminishing it, yet in certain cases medicines are useful.

Nervous cough will be treated at first by self-control, then by bromide of potassium, if necessary.

Bromide of potassium, 1 dr.

Cherry laurel water, 2 dr.

Syrup of ether, 1 oz.

Elderflower water, 4 ozs.

Three or four tablepoonsful a day.

When the cough is due to simple irritation of the larynx, gargles will be found useful:—

Naphthol B., 3 grs.

Perborate of soda, 4 drs.

Tincture of aconite, 15 drops.

Peppermint water, 6 ozs.

Boiled water, 34 ozs.

If this treatment does not succeed, the back of the throat may be painted with:—

Hydroch. of cocaine, 5 grs.

Water, 3 ozs.

or

Resorcin, 15 grs.

Cocaine, 2 grs.

Glycerine, 1 oz.

Where the cough is evidently due to irritation of the larynx, hot compresses might be placed to the front of the neck and the parts sprayed with:—

Coca leaves, 1 dr.

Boiling water, 10 ozs.

Carbonate of potash, 1 dr.

Essence of peppermint, 5 drops.

Or inhalations of hot water, to which are added a few drops of eucalyptol or gomenol.

If the above means do not succeed, the following might be tried:—

Tincture of aconite, 15 drops.

Tincture of belladonna, 12 drops.

Tincture of bryony, 12 drops.

Bromide of potassium, 1 dr.

Elder flower water, 6 ozs.

Four or five tablepoonsful in the twenty-four hours.

Tuberculous laryngitis is best treated by a specialist, as it requires an expert hand.

Another cause of the cough lies in difficulty of expectoration, and here expectorants are naturally indicated, the most simple of which are effervescent drinks as seltzer water or the inhalation of aromatic vapours:—

Tincture of benzoin, 1 dr.

Glycerine, 5 drs.

Water, 3 ozs.

and

Dover's powder }  
Terpine } 1 gr.  
Tolu }

For one pill, five or six in the twenty-four hours.

Another kind of cough is the gastric cough, known since the time of Hippocrates, and characterised by being dry, short and coming on after meals. It is dangerous, for it may be followed by hæmoptysis and vomiting; several remedies should be used in turn, if necessary, against it. The patient should first be put on a lacto-vegetarian diet: a few minutes before the repast, five or six drops of laudanum in a little water; after the repast, four to six drops of dionine in cherry laurel water:—

Dionine, 3 grs.

Cherry laurel water, 2 drs.

When the cough comes on half-an-hour after meals:

Cocaine, 1 gr.

Codeine, 1 gr.

Lime water, 6 ozs.

Chloroform water, 1 oz.

Where the cough is of bronchial or pulmonary origin, recourse might be had to inhalations of medicated vapours, while the secretion will be reduced by opium and datura:—

Extract of opium, 1-5 gr.

Extract of datura, 1-10 gr.

For one pill; three pills at an interval of half-an hour between each.

Dry cupping, mustard application, actual cautery, small blisters might be tried in turn.

There exists another drug, little known, and yet very useful; it is orthoformiate of ethyl; it is given at the dose of 10 drops on a lump of sugar and renewed every hour or two.

*Hæmoptysis.*—Hæmoptysis has always a considerable moral effect. It frightens both the patient and his family, who require to be reassured. The possibility of a return of the accident should be frankly stated in order that the means prescribed to avoid a recurrence of the hæmorrhage should be seriously observed.

The patient should avoid all effort as well as animated conversation, throwing his arms about, staying up late; the temperature of the room should not exceed 65° F.; in walking out of doors the patient should avoid the sun's rays. Everything exciting in the food must be suppressed, while milk must be the only drink allowed.

Such drugs as creosote and every form of arsenic, organic or mineral, will also be suspended if the patient had been undergoing this treatment.

Remedies against hæmoptysis, when it appears, are not wanting. Applications of mustard to the legs (not the thorax) and a mustard foot-bath when possible; ether spray down the spinal column frequently succeeds in arresting the hæmorrhage. In the meanwhile, the following two mixtures will be prepared:—

Ergotine, 1 dr.

Gallic acid, 10 grs.

Syrup of turpentine, 1 oz.

Water, 4 ozs.

A tablespoonful every hour.

Chloride of calcium, 1 dr.

Syrup of opium, 1 oz.

Water, 4 ozs.

A tablespoonful every hour, beginning at the half-hour.

If the hæmoptysis persists in spite of the above, a subcutaneous injection of gelatine might be made:—

Gelatine (sterilised), 5 drs.

Chloride of sodium, 2 drs.

Boiled water, 1 quart.

Five drachms will be injected once or twice a day.

The following pills might also be prescribed, if necessary:—

Hippo, 1 gr.

Powdered digitalis, 1 gr.

Extract of opium,  $\frac{1}{4}$  gr.

Or one pill; five to six daily.

*Dyspnœa.*—Dyspnœa will be treated by rest and immobility. When it does not yield, ten drops of validol or valerianate of menthol on a lump of sugar may be prescribed every two hours, or oxycamphor in alcoholic solution, at 50 per cent, at the same dose, or again the fluid extract of euphorbium pilulifera in five-drop doses, five or six time a day.

*Fever.*—The fever due to tuberculosis should rarely be treated, for the antithermic drugs that might be prescribed fatigue the stomach. It should consequently be left alone, except under the following circumstances:—

1.—When it is intense and really injurious to the patient.

2.—When the attacks come on at meal-time, hindering the patient from taking sufficient food.

3.—When the patient worries over it and expects to be relieved.

A good method is cold sponging; it frequently succeeds.

Among the antipyretics, four only should be employed: antipyrine, pyramidon, cryogenine, aspirine. The first-named should be rarely given. The following wafers are preferable:—

Pyramidon, 2 grs.

Cryogenine, 2 grs.

Caffein,  $\frac{1}{2}$  gr.

They should never be given at the moment of the fever, but at eight in the morning and nine in the evening.

**Sweats.**—Sweating weakens the patient greatly and hinders sleep; it should therefore be treated, and for this purpose several drugs are at our disposal, such as tellurate of soda (1-5 of a gr. in pill, three or four daily); tincture of hydrastis canadensis (thirty drops at bed-time); oxide of zinc (5 grs. in a wafer) an hour after dinner.

If all these means fail:—

Agaric powder, 5 grs.

Belladonna powder,  $\frac{1}{2}$  gr.

Camphoric acid, 4 grs.

Jaborandi powder,  $\frac{1}{2}$  gr.

For one wafer to be taken at bed-time.

**Dyspepsia.**—Dyspepsia is one of the most serious accidents, for a consumptive patient who eats and digests well will have a chance of recovery.

The gravest dyspepsia is hypersthenia. Out of 100 patients in the first stage of the disease, M. Robin found 70 cases of hypersthenia; in the second period, 60 cases, and in the third 76 cases of hypersthenia and chronic gastritis.

When a patient is suffering from dyspepsia all antibacillary drugs should be suppressed and the nature of the dyspepsia defined.

In case of hypersthenia, animal food should be reduced and the ingestion of raw meat suppressed. Before each repast five drops of the following mixture will be prescribed:—

Tincture of opium, }  
Tincture of belladonna } 2 drs.  
Tincture of hyoscyamus }

and at the end of each repast:

Hydrate of magnesia, 1 dr.  
Carbonate of lime, 2 drs.  
Phosphate (tribasic) of lime, 1 dr.  
Sugar, 1 dr.

Divide into twelve powders; one powder in a little water.

If, on the contrary, hyposthenia is present, the animal regime will be increased on the condition that the meat be reduced almost to a jelly or purée. As an aperitif, the following wafer will be prescribed immediately before each meal:—

Sulphate of potash, 1 gr.  
Bicarb. of soda, 5 grs.  
Hippo powder, 1-5 gr.  
Carbonate of lime, 2 grs.

If gastric fermentation is observed, the quantity of food at each repast will be diminished, but the number of meals will be increased, while the contents of the stomach will be saturated with:—

Bromide of ammonium, 6 grs.  
Water, 10 oz.

A tablespoonful at each meal.

For chronic gastritis, hydrochloric acid and digestive ferments may be given with success.

**Vomiting.**—Vomiting may be caused by the cough, or by dyspepsia. The following drops will be found useful in such cases:—

Picrotoxine, 1 gr.  
Morphia, 1 gr.  
Atropine, 1-5 gr.  
Ergotine, 15 grs.  
Cherry laurel water, 3 drs.

Five drops in a little water before meals, but the entire quantity for the day should not exceed 25 drops.

A small blister over the epigastrium may be tried, and the raw surface powdered with a quarter of a grain of opium.

**Diarrhoea.**—Diarrhoea will be treated by modification of the regime or by raw meat, eggs, rice water. The range of drugs is extensive: tannigene (10 grs. in wafer, three or four times a day); dermatol (10 grs. three or four times daily); oxide of zinc (1 dr. at one time); tannalbin (15 grs. four times a day); enemas of starch and laudanum. A compress steeped in cold water applied to the abdomen and covered with oil silk, cotton-wool and maintained by a bandage, renders frequently great service.

## GERMANY.

Berlin, July 4th, 1909.

In the *Archiv. f. Laryngologie*, XXI., 1, is a paper by Dr. Spiess on

THE IMPORTANCE OF ANÆSTHESIA IN THE TREATMENT OF INFLAMMATION, AND ITS SPECIAL EMPLOYMENT IN THE TREATMENT OF LARYNGEAL TUBERCULOSIS.

The treatment described rests on the basis of the following theory: Through the pain, in the extended sense—i.e., the excitation of centripetal nerves—hyperæmia, and eventually a tumour, are caused by reflex action, until the sensory nerves are deadened and anæsthetised by the pressure of the exudation, as by Schleich's infiltration; with the disappearance of the nerve effect causing the reflex action, the hyperæmia also disappears, and with it the tumour. Why not save Nature the circuit round the inflammation, and set up the curative anæsthesia artificially?

Acting from this point of view, the writer has treated cases of tuberculosis of the larynx with marked success. The best results were obtained with sub-mucous injections of 1 to 2 ccm. of a 2 to 5 per cent. aqueous solution of novocain once or twice daily, or oftener, if the sensitiveness was very great. He employs this method of treatment not only in the treatment of the tuberculous affection itself, but also in the post-operative stage. The first application is usually made after a preliminary application of cocaine.

At the Medical Society Hr. Albu read the report of THE COLLECTIVE INQUIRY COMMISSION ON INFLAMMATIONS OF THE CÆCUM IN GROSS-BERLIN IN 1907.

There were 3,498 answers to inquiry sheets, of which 76 per cent. were from hospitals, the remainder from general practitioners. Autopsies in the fatal cases showed errors of diagnosis in 3.33 per cent.; these were mostly cases of disease of the ovaries and tubes of females.

For statistical purposes 3,016 were available. The mortality in hospital was 9.2 per cent., in private 1.7 per cent., but here the cases were all of the milder type. From the calculations afforded by the figures, about 2 per 1,000 of the population of Berlin suffered from appendicitis annually. Ætiologically, enterogenous infection by *B. coli* and streptococci played the leading part; in a few cases trauma, chronic catarrh of the colon, and intestinal atresia were given as the cause.

As regarded symptoms, in 55 per cent. the disease was accompanied by constipation, in 90 per cent. by abdominal pain, in 62.5 per cent. by fever, in 57 per cent. by acceleration of the pulse. *Défense musculaire* was only slightly observed, but general tension of the abdominal walls was the rule.

Of the cases that were operated on during the first attack, 82 per cent. had abscesses; amongst those operated on during the second attack, 10 per cent. had abscesses; whilst in operations during the third they were found in only 3.3 per cent. of the cases.

The mortality was greatest in first attacks, and diminished with the frequency of them.

The possibility of early operation was not unfrequently rendered null by difficulties of diagnosis, and because the patient had not obtained medical aid in time. The public should be warned to call in the physician in every suspicious case.

In chronic appendicitis a distinction had to be made between the relapsing and the insidious form. Of the former 229 were treated, with 40 fatalities; of the latter 112, with 1 death; 54.5 per cent. of the cases were males.

Hr. Rotter read the report on the treatment. In

round numbers, 3,000 cases were treated, of which 2,705 were acute; 2,365 were treated in hospital, 1,300 by operation, with a mortality of 14.6 per cent. Of these, 423 cases were operated on in the early stage—i.e., during the first 48 hours, with a mortality of 5.6 per cent.; 105 were operated on the first day, and of these only 1 died, whilst of 318 operated on the second day, 22, or 7 per cent., died; on the following days the mortality ran on to 10, and up to 23 per cent., so that in those operated on after the second day the average mortality was 18 per cent.

Of the 1,021 cases not operated on, 17 died—1.6 per cent.—and of the 340 treated at home, only 6 died—1.7 per cent. These figures are low for the reason that all these cases were mild ones. Of 902 chronic cases operated on, 9 died—0.9 per cent.

The results at the Hedwigs Hospital were, on the whole, similar to those obtained in the "Collective Inquiry," except that the mortality in those operated on during the first 48 hours was 1.9 per cent., against 5.6 per cent. of the larger collection. The reason for this was that at the Hedwigs Institution all the cases of medium and great severity were operated on early, whilst some operators took the stand that only the most serious cases should be operated on at once, when the figures must necessarily show worse results. From statistics of the Hedwigs Hospital going back to 1893 it appeared that, so long as conservative principles were followed, the results were much the same year after year, and no improvement set in until early operation was introduced in 1905. In late operation, also, the results had improved, for the reason, as he thought, that he now followed the plan of Rehn of thoroughly washing out both the bowel and the abdominal cavity.

The statistics of other operators also showed an improvement since the abandonment of the conservative method of treatment.

Those of Stricker show only a mortality of 3.1 per cent., but this is assumed to be accounted for by the fact that all the cases were those of soldiers who came under treatment when they were young and strong, the average age being about 20.

On summing-up the results of treatment the speaker concluded that early operation gave the best results. To await the subsidence of the attack and operate in the free interval was not without its risks, as experience showed that most of the fatalities occurred during first attacks.

## AUSTRIA.

Vienna, July 4th, 1909.

### THE THYROID EPITHELIAL BODIES.

KREIDL demonstrated a cat which he had operated on in the laboratory along with Yoshimura in 1906. They first performed thyreo-parathyreodectomy in such a manner as to extirpate the epithelial bodies; the remainder of the gland was destroyed a few days later by the galvano-cautery. The animal never showed any sign of tetany, either during or after the operation.

In the course of a month the left motor region was extirpated, and 24 hours thereafter the animal had an epileptic fit, which was checked by pressing the nerves of the fore feet, but after a few days the animal resumed its normal state. A month later the right motor centre was extirpated as the left had been with a similar result, viz., epileptic fit, and checked by pressure on the nerves of the fore feet after a few seconds. The animal has since had trophic disturbance of the teeth and falling out of hair.

### ERYTHRODERMIA EXFOLIATA.

Ehrmann presented two cases with peculiar form of skin disease which he diagnosed erythrodermia exfoliata generalisata. The first was a male, æt. 60, who previously had had psoriasis. Since February last, the whole skin from the crown of the head to the sole of the foot was red, inflamed, some parts weeping; others covered with a dry scurfy lamellæ, while the hair had entirely fallen out, leaving a fine lamigo in its stead. The face was covered with a fine scurf, and not so picturesque as the body which had the large lamellæ, reminding one of the crocodiles' covering, with

the large rhombic plates, some of these being as large as a two-shilling piece. The glands of the groin ranged from the size of a walnut to that of an egg.

The Rontgen rays were applied with wonderful success, the redness and desquamation having nearly gone, while the glands are reduced to the size of marbles. This is a great advance in a disease that formerly took months, nay, years to accomplish, what can now be done in a very short time.

The second case was that of a female, æt. 40, who also had psoriasis at one time, which subsequently became intermittent, but lately assumed an intense reddening of the entire skin with portions weeping, and others covered with a lamella, as in the former case. The patient in this case was febrile at the onset, the temperature ranging from 37.5° to 38.5° Centigrade, or 99.5° to 101.3° Fahr., with general swelling of all the glands, examination of the blood gave 13 per cent. of eosinophile cells, while the lungs were distinctly infiltrated at the apex. This case may therefore be placed in the group of general idiopathic erythrodermia, depending entirely upon a morbid condition of the blood, and may primarily originate in one of the internal organs. The disease from this point of view is closely connected with leucocythæmia, pseudo-leukæmia, sarcomatosis universalis, mycosis fungoides in the early stage, and tuberculosis. It seems strange that all these forms, in spite of their different ætiology, resemble one another in their blood origin, probably from some toxic or parasitic toxine.

### GUNSHOT WOUND AND TUBERCLE.

Schnitzler presented a patient with a remarkable history after receiving a gunshot wound in the abdomen. From the symptoms of internal hæmorrhage it was deemed prudent to operate at once.

On opening the abdomen the small bowel was observed to be loaded with tubercular nodules along its whole length, although the patient had never complained or felt unwell at any time before the accident. Many of them had ulcerated, as the ulceration could easily be felt through the wall of the bowel. In the peritoneal cavity a quantity of serous fluid coloured with blood, was present. Tuberculin in the eye gave an active reaction in accord with the finding in the bowel. At the laparotomy the bullet was found to have passed through the renal artery and side of the spleen, which was causing a great loss of blood into the peritoneum. The spleen was removed, the artery tied, and the wound closed with a good result.

After showing sections of the extirpated spleen, he showed the members an enormous calculus he had removed from the bladder of a patient by the sectio alta. Its dimensions were 16 by 11 by 6 centimetres, and weight 500 grams, or one pound two ounces nearly. This enormous stone gave no more trouble to the patient than to check the flow, all other symptoms being absent—the urine was clear and free from blood. Schuller had tried lithotripsy before the operation, but failed, as the hardness of the stone resisted all pressure.

## FROM OUR SPECIAL CORRESPONDENTS AT HOME.

### BELFAST.

THE SCHOOL PROBLEM IN IRELAND.—Sir William Whitla, in opening some new national schools last week in Portadown, dwelt at some length on the question of the state of Irish schools, which, he said, was, with few exceptions, deplorably unsatisfactory from a sanitary point of view. The most serious defect was the scandalous inefficiency of the ventilation, whereby, he was certain, many children's lives were lost, while others were crippled for life. The cry of the languishing child doomed to breathe such air rose to Heaven, though it was drowned by the din of party strife and the clamour of political agitation, the shrieks of suffragettes, the hysterics of the anti-vivisectionist, and other well-meaning but misguided people. Every function of the child was depressed, and every organ starved and stunted in its development by the

polluted air, so that their death-rate from tuberculosis in Ireland had become a standing disgrace.

**BRITISH MEDICAL ASSOCIATION.**—It has been announced that his Excellency the Lord Lieutenant and Lady Aberdeen have arranged to visit Belfast during the approaching meeting of the British Medical Association, and to attend several of the functions connected with the meeting. These will probably include the President's address on Tuesday the 27th inst., the annual dinner of the Association on Wednesday, 28th, and the Lord Mayor's reception in the City Hall on Thursday, 29th. A number of American and foreign guests will also be present at the meeting, and elaborate preparations are being made for their reception and entertainment.

Dr. JOHN MILROY, Lecturer in Physiology in Queen's University, has been appointed to the new lectureship in Bio-chemistry in the University.

## LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

### THE TIMES AND QUACK ADVERTISEMENTS. *To the Editor of THE MEDICAL PRESS AND CIRCULAR.*

SIR,—In a recent issue of THE MEDICAL PRESS, a "Medical Temperance Reformer" drew attention to a leading article in the *Times* which elaborately exposed the evils arising out of the traffic in sham tonics containing alcohol, and strongly advocated legislation to prohibit the sale of these pernicious compounds. I have just come across the subjoined excerpt from another later article in the *Times* dealing with the syllabus upon "Temperance" for use in primary schools:—

"We think that a syllabus upon 'Temperance' might with advantage contain lessons upon the dangers of things which are even more insidious than alcoholic drinks, and to which there is only too much reason to believe that many total abstainers have recourse—namely, to preparations of opium, or to the many extensively advertised quack medicines which afford brief tranquillity to the nervous system by sedative drugs of one description or another, such as morphia, cocaine, kola nut, and their analogues, which entail consequences at least as disastrous as those of alcoholic intemperance, and which are less readily brought under control."

Now, Sir, I am not a reader of the *Times*, and I know nothing about its advertising pages; but I do know that most of the leading papers of the day are deriving enormous incomes from advertisements of the harmful compounds denounced by the *Times*, and that these concoctions could not gain the enormous sale they command without the help of newspaper advertisements, and puffs in form of editorial paragraphs now inserted for pay in most papers. Cannot you, Sir, induce your great contemporary to add one more to the many great services it has in past days conferred upon the people by making all the facts with regard to the quack medicine trade so conspicuously prominent that no respectable newspaper dare continue to derive income from so foul a source? If the Editor of the *Times* is not fully supplied with the information needed for such a task, a volume or two of your estimable journal would more than sufficiently provide it.

I am, Sir, yours truly,  
RUSTICUS, M.B.

### PREVENTION OF DENTAL CARIES.

*To the Editor of THE MEDICAL PRESS AND CIRCULAR.*

SIR,—Dr. Robert Lee seems a little dogmatic in declaring that the main cause of dental caries is not improper feeding, but rather "some defect in the pulmonary condition of infants" and "imperfect blood aeration." This seems to me to be putting the cart before the horse. One might as well ascribe pneumonia to "imperfect blood aeration"; it is an effect not a cause of the disease; just as in rickets no doubt imperfect blood aeration would be present in cases during the vital depression of slow starvation

from lack of assimilable food. Not only in this country, but on the Continent, and especially in the institutions in late years established in many parts of France for the help of poor mothers and their offspring, it has been noted by all observers that infantile mortality and infantile malnutrition are mainly governed by feeding. The infants of healthy mothers able to feed them naturally throughout the proper term do not die, and do not develop rickets, or diseases of malnutrition. In proportion as the maternal supply is imperfect, and in proportion as it is made up by inferior substitutes, constitutional disabilities increase. The greatest mortality, and the greatest damage to the physique of survivors is observed in the infants who get very little milk either derived from their mothers, or the cow, and are fed with all kinds of things such as fragments of their parents' food, with which their digestive organs are absolutely incapable of dealing. When in addition the infant is systematically dosed with narcotic quieters in quack nostrums the mischief reaches its maximum. The downward course is doubly hastened by the damp, dark, unventilated dwellings, and filth of person and environment which form the lot of most of the infants of the very poor. As a hospital dentist having availed myself of my ample opportunities of studying infantile constitutional defects during many years, and being besides fairly well acquainted with the literature of the subject, I hope that the expression of my strong opinion in entire disagreement with that of so distinguished a physician as Dr. Robert Lee may not appear too presumptuous.

I am, Sir, yours truly,  
M.R.C.S., L.D.S.

June 30th, 1909.

### THE NORMYL TREATMENT.

*To the Editor of THE MEDICAL PRESS AND CIRCULAR.*

SIR,—Mr. Porteous affirms that over 150 doctors have prescribed the Normyl treatment for their patients. If this is so it seems a pity that their names cannot be ascertained, and their conduct brought before the notice of the Medical Council. To prescribe a secret remedy is a very grave professional offence meriting severe punishment. But when one speaks of a "secret" remedy it is always to be borne in mind that there exist no secrets to analytical chemistry; and as soon as it is worth while, anyone who cares to take the trouble can ascertain the constituents of the Normyl medicines. It is, however, not worth the trouble. The constituents can be only drugs, the action of which are thoroughly well understood by the profession; drugs which, if they have any power such as that claimed for the Normyl remedies, have been used, and are being employed by qualified men everywhere. Any drug or combination of drugs which would cure drunkenness would perform a miracle. Drunkenness is not due to one cause, nor is it a kind of "possession" to be exorcised or driven out by a single remedy. It depends upon an exceedingly complex mass of causes, physical, mental, moral, infinitely varying in different cases; whilst in long continued alcoholism there are brought about easily demonstrable coarse degenerative changes—destruction of tissue elements in the brain—which only a miracle could repair. Is there not really a commercial aspect of the Normyl enterprise. Is not some one making money by the "secret" remedy. The proper course for philanthropists is to make known fully and freely for the benefit of suffering humanity all over the world the methods and means of their treatment. This is the course always pursued by medical men and men of science. As long as secrecy is maintained it is the duty of every medical man and every man of the world to disregard it. It has no more claim to attention than the scores of advertised cures for every disease, the claims of which are backed by many more testimonials from grateful patients than the directors of the Normyl treatment can possibly boast of. Most of such advertised positive cures for incurable diseases turn out on analysis to contain no ingredient capable of causing any physiological reaction of any sort. If the Normyl managers will submit their remedies to some im-

partial scientific tribunal they may easily satisfy themselves as to the character of the illusions they are cherishing.

I am, Sir, yours truly,  
MEDICAL TEMPERANCE REFORMER.

June 30th, 1909.

#### THE REMOVAL OF GROWTHS FROM THE VOCAL CORDS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In Dr. Hill's enthusiasm for the removal of growths from the vocal cords by means of direct vision (MEDICAL PRESS AND CIRCULAR, June 30th, 1909, p. 660), he scarcely does justice to the "old indirect mirror and forceps method." It is no exaggeration on Dr. Hill's part that with the method he employs "the patient comes into the hospital one day with a growth and *minus* a voice, and leaves the institution on the next day *minus* the growth and *plus* his voice." At the same time, Dr. Hill, and all those who have faithfully practised intra-laryngeal operation under reflected light must, like myself, have repeatedly had the experience of the patient coming "with a growth and *minus* his voice," and leaving within an hour or so "*minus* the growth and *plus* his voice," without any other anæsthetic except cocaine applied locally. There are undoubtedly cases of difficulty under either method, but the experience above narrated with the indirect one is by no means unusual with the simple instruments with which Morell Mackenzie and his successors have been so successful.

I am, Sir, yours truly,  
DUNDAS GRANT.

London, June 30th, 1909.

#### A GOOD CAUSE.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The Hospital for Invalid Gentlewomen, established at 90 Harley Street, fifty-six years ago, by Viscountess Canning and Miss Florence Nightingale, is closed owing to the expiration of the lease. A new hospital for 32 patients is in course of construction at 19 Lisson Grove, and will be opened for the reception of patients towards the end of the year. £5,000 are still needed to complete the building and equipment. Should any of your readers feel inclined to assist in this good work, donations may be sent to me direct at 13 Mansfield Street, W.

I am, Sir, yours truly,  
W. C. BRIDGEMAN, M.P.

#### OBITUARY.

GEORGE ARCHIBALD MACONACHIE, M.D. ABER.

WE regret to announce the death of Dr. George Archibald Maconachie, of Aberdeen. Dr. Maconachie studied at the Aberdeen Grammar School, and took his medical course at Aberdeen University, graduating M.B., C.M. in 1866. He received the degree of M.D. in 1872. A year after graduation—namely, in April, 1867—he entered, by competition, the Indian Medical Service, Bombay, where he had a distinguished career. He held various medical appointments, and took part in the Abyssinian War, acting as Medical Officer of the reconnoitring force, and being present at the fall of Magdala. Subsequently Dr. Maconachie was appointed a professor in the Government Medical College, Bombay, and soon afterwards became Principal as well as Professor, and in that dual capacity obtained a large experience in administrative affairs. For upwards of twenty-five years he was a member of the Bombay Educational Department, and besides his connection with the Medical College, held other appointments in Bombay University. He retired from the service in which he had earned so much distinction with the rank of Brigade-Surgeon Lieutenant-Colonel in June, 1891, and afterwards took up residence in Aberdeen.

DR. PETER A. YOUNG, OF EDINBURGH.

ANOTHER prominent member of the medical profession has also passed from our midst in the person of

Dr. P. A. Young, lately Treasurer of the Royal College of Physicians of Edinburgh. Dr. Young was for many years in active practice in Edinburgh, and though he never occupied any hospital or teaching appointments, he was always in active sympathy with medical education and administration, and was for a number of years a manager of the Royal Infirmary. He was Treasurer of the Royal College of Physicians until a year ago, and the College owed much to his management of their finances. Apart from his purely professional work, his first interest was in the affairs of the College. Dr. Young was an enthusiastic Volunteer, and an ardent supporter of the cause of temperance. About three years ago he had a serious affection of the throat which gave rise to great anxiety, and although the fears which it caused were not realised, for he made a complete recovery so far as the local condition was concerned, he never really got over this illness, and for the past year or eighteen months his health gradually failed. He left Edinburgh for the South last autumn, and died at Bournemouth on Friday last.

DR. FINLAY, W.A., OF EDINBURGH.

WE regret also to have to announce the death of Dr. Finlay, which took place at Nairn on June 24th. Dr. Finlay, who was a brother of Sir Robert Finlay, K.C., M.P., was the leading practitioner in the Trinity District of Edinburgh. He had a very large practice, and was for many years Surgeon to Leith Hospital, a post which he resigned in the early nineties. In the autumn of last year his health began to fail, and signs of malignant disease of the œsophagus developed; he was compelled to relinquish his practice and retired to Nairn, his native place. Both Dr. Young and Dr. Finlay were men of the highest type—honourable, upright, courteous, and genial; the greatest sorrow was expressed when it was learned that both of them were compelled through such serious illness to retire from work, and their deaths have cast a gloom over the medical community.

#### SPECIAL ARTICLES.

##### COMPLIMENTARY BANQUET TO SIR FELIX SEMON, K.C.V.O., M.D., F.R.C.P.

ON Friday, the 2nd inst., a large and distinguished company met at the Whitehall Rooms, Hotel Metropole, London, at a complimentary banquet given to Sir Felix Semon, the well-known laryngologist, on the occasion of his retirement from practice.

There were 250 guests, including the Duke of Fife, Count Metternich (German Ambassador), Sir James Reid, Bt., Sir Squire Bancroft, Sir Ernest Cassel, Sir James Dewar, Sir Hubert Herkomer, Sir George Lewis, Sir John Fletcher Moulton, Sir Gilbert Parker, Sir A. W. Pinero, Sir Beerbohm Tree, Sir Charles Wyndham, Sir Henry Morris, Bt., Sir Charles Mathews, Sir Thomas Barlow, Bt., Sir Julius Wernher, Bt., Sir Anderson Critchett, Bt., Sir Victor Horsley, Dr. Dundas Grant, Mr. Henry J. Davis (Hon. Secretary), and Dr. H. Birkett. There were also present a large number of ladies, including a considerable representation of the literary and theatrical professions, amongst them being Mrs. Alec Tweedie and Mrs. Patrick Campbell.

Dr. Davis announced, after the loyal toasts had been honoured, that the subscriptions to the testimonial fund amounted to £1,200, and that contributions had been received from laryngologists in Austria, France, Germany, Russia, Italy, Sweden, and America; while letters had been received from gentlemen all over the world conveying expressions of regret at inability to be present.

The Chairman, in submitting the toast, "Our Guest," gave a sketch of the career of Sir Felix Semon, and spoke of the condition of specialists in London at the end of the sixties of the last century. The throat specialist and the skin specialist were detested—it was more than once stated that no man who practised as such could make a decent income without robbing the public. On that account specialists were kept out of the general hospitals, and

they formed special hospitals, which were even more obnoxious to the profession than specialists themselves. Sir Felix Semon, thirty-three years ago, came to London, having taken his degrees in medicine at the German Universities. He visited the Hospital for Diseases of the Throat in Golden Square, and there found a great wealth of material and ample opportunity for studying the use of the laryngoscope. In the course of time he was appointed clinical assistant to Sir Morell Mackenzie, and in 1877 he settled down in London to practice as a throat specialist.

In 1881 the International Medical Congress was held in London, and Sir Felix Semon was able to obtain the first recognition for laryngology at that congress. A couple of years later he was appointed physician in charge of the department for diseases of the throat at St. Thomas's Hospital, and held that post for fifteen years. Later, it was no surprise to those who knew him well when they saw his name for the first time in the list of honours, and heard that he had been appointed to the Royal Household.

Since the news of his retirement became known, laryngologists said to one another that they could not allow him to go without marking their regard for him. They had some hope that they might be able to found a scholarship connected with laryngology, or something associated with him. This idea was received with such enthusiasm by his friends, who contributed so liberally that they would be able to found a scholarship or lectureship, by means of which his name would be associated with laryngology in London for many years to come.

Five speakers supported the toast.

After Mr. Alfred Mond, M.P., had spoken,

Dr. Dundas Grant, President of the Section of Laryngology of the Royal Society of Medicine, presented to Sir Felix an album of photographs of British laryngologists, and stated that Sir Felix was founder of the British Laryngological Society, which largely owed its success to his energy.

Dr. H. S. Birkett, of Montreal, ex-president of the American Laryngological Association, on behalf of medical friends, presented Lady Semon with a beautiful brilliant.

Sir H. Beerbohm Tree, making a presentation of an album containing photographs of friends in the dramatic profession, said he had always regarded Sir Felix as a lovable altruistic egoist, and he hoped he might long continue as such.

Sir Hubert von Herkomer and Dr. George Finder, of Berlin, also spoke.

Sir Felix Semon, responding, acknowledged the great honour conferred upon him, and stated that the King, whom he had had the honour of serving for very many years, and who had bestowed upon him so many marks of his Royal favour, had been graciously pleased to signify his wish that he should continue to be one of his Physicians Extraordinary. The evening concluded with a musical entertainment.

gery is yet so dark and unexplored as that which contains fractures and minor injuries. A great deal of light is thrown into it by these simple, straightforward essays of Sir William Bennett, which by their common-sense should make the blush mantle to the cheek of many of his highly-placed colleagues in the profession. As the little work is now in its fourth edition we need not deal with in detail; it is essentially a clinical work by a clinician, and to the general practitioner it should be thrice blessed, both for what it will bring him and for what it will bring his patients, if he sets himself to the practices inculcated.

## MEDICAL NEWS IN BRIEF

### Royal College of Surgeons of England—The Museum.

THE annual exhibition of specimens added to the College Museum during the past collegiate year was visited by more people than for many years past, the collections of Egyptian and Congo Free State skulls affording much pleasure to those interested in the history of primitive races. Much of the credit for the success of the exhibition is due to the Conservator, Dr. Arthur Keith, whilst his assistant, Mr. R. H. Burne, and Mr. S. G. Shattock, the pathological curator, contributed to the success in no small measure by the excellence of their physiological and pathological preparations respectively.

### The Royal College of Physicians of Ireland.

THE College will proceed in October next to fill the Chair of Midwifery in the School of Physic, Trinity College, Dublin, rendered vacant by the death of Sir Arthur Macan in September last. The King's Professorship of Institutes of Medicine will also be vacant, as the term for which the present occupant of the Chair—Dr. Walter Smith—was appointed is coming to an end. A fresh election is necessary under the Statute, and Dr. Walter Smith is eligible for re-election.

### Royal Society of Arts.

THE Council have awarded the Society's Silver Medal to the following readers of papers during the Session, 1908-9:—Mr. G. Albert Smith, "Kinematography in Natural Colours"; Mr. Henry C. Brewer, "Gothic Art in Spain"; Monsieur Yves Guyot, "The Commercial Relations of France and Great Britain"; Mr. George Hubbard, "Dew-ponds"; Mr. Walter Rosenhain, "The Application of the Microscope to the Study of Metals"; Mr. Gabriel Gordon Cleather, "The Musical Aspect of Drums"; Mr. C. Reginald Enock, "The Resources of the Peruvian Andes and the Amazon"; Mr. Percy A. Wells, "English Furniture Design and Construction"; Mr. Arthur John Barry, "Railway Development in China"; Herr Sam Eyde, "The Manufacture of Nitrates from the Atmosphere by the Electric Arc"; Mr. Douglas Dewar, "The Birds of India"; Mr. Arthur Anthony Macdonell (Boden Professor of Sanskrit, Oxford), "The Buddhist and Hindu Architecture of India"; Mr. Selwyn Howe Fremantle, "The Problem of Indian Labour Supply"; Mr. Krishna Govinda Gupta (Member of the Council of India), "Some Phases of Hinduism"; Mr. Cecil L. Burns (Principal, Bombay School of Art), "The Functions of Schools of Art in India"; the Hon. Charles Gideon Murray, "The Road to South African Union."

### New Sanatorium for Delicate Children.

IN the scheme of the National Children's Home and Orphanage there has long been realised the need of a sanatorium and open-air school for such little ones who, though not actually consumptive, show signs of predisposition to tubercle. This deficiency is now to be met, and a large company travelled on June 23rd to Harpenden to witness the laying of three memorial-stones, and to judge for themselves how admirable a site for such a purpose has been secured. The committee were able to secure an estate of 200 acres under favourable conditions, and will devote about ten acres

## REVIEWS OF BOOKS.

### MASSAGE IN FRACTURES AND SPRAINS. (a)

SIR WILLIAM BENNETT has been the leading pioneer in this country of the methods of Professor Lucas Championnière, and he has been chiefly instrumental in breaking up the old rule-of-thumb fixation treatment for fractures and sprains, which sent more people limping through the world than all Napoleon's campaigns. In medicine less than anywhere is there room for rules and doctrines, and the charm of its practice is the enormous scope it gives for individuality in the management of patients. Even now many surgeons are content to leave their fractures to their house-surgeons, and in the old days the treatment began and ended with the splint. Happily, a little more science has been imported into the management of these injuries, and we say unhesitatingly that no field of sur-

(a) "Lectures on the Use of Massage and Early Movements in Recent Fractures, Sprains, Rigidity of the Spine, and the Management of Stiff Joints." By Sir William Bennett, K.C.V.O., F.R.C.S., Consulting Surgeon to St. George's Hospital. Fourth Edition. 23 Illustrations. London: Longmans, Green and Co. 1909.

on its highest point, which is 430ft. above the sea level, to the new project. It is estimated that the cost will be approximately £12,000, of which £9,000 is already promised. The buildings will at first accommodate forty children, with an adequate staff of nurses and teachers, though provision will be made for enlargement if necessary. Dr. T. N. Kelynack is honorary medical adviser to the institution, and his plans in this direction have won the cordial approval of Sir Thomas Barlow, who publicly commended them at a Mansion House meeting last year. The architects are Messrs. Holman and Goodrham.

The stones were set in position by Miss Marshall, daughter of Sir Horace Marshall; Miss Ainsworth, a niece of Sir Thomas Barlow, and Alderman Sir Charles Wakefield, who presided, and acted thus on behalf of Miss Perks, daughter of Sir Robert Perks, unavoidably absent through the illness of a relative. Among those present were Lady Wakefield, Sir Horace and Lady Marshall, the Rev. Joseph Shrimpton (chairman of the Bedford and Northampton Wesleyan Synod), and the Rev. George Hooper (president of the Metropolitan Free Church Council). Sir Thomas Barlow wrote expressing his regret at being unable to attend and saying that the sanatorium would be a real Godsend to many children just over the border-line, who would receive the most thorough and advanced methods of hygienic treatment.

#### Damages for Barber's Rash.

AT Clerkenwell, on the 2nd inst., Harold Maurice Carter, a civil servant, of Oakhurst Grove, East Dulwich, was awarded 20 guineas and costs against W. Fowler, a Gray's Inn Road hairdresser, for an attack of barber's rash. His claim was for £50.

His Honour Judge Edge, after hearing the evidence, said that he had no doubt the rash was brought on through the use of some instruments that were not in the condition in which they ought to be, although there was no personal fault on the part of the proprietor of the shop.

#### Murders by an Indian Student.

THE second victim of the murderous attack by an Indian student named Dhingra, after shooting Sir W. Curzon Wylie, was Dr. Lalca, a Parsi doctor, who was killed by a bullet which entered just below the right breast and passed out behind the left shoulder. He is a resident of Shanghai, but originally belonged to Bombay. He came to this country on a visit only a few weeks ago, and was staying at the Grand Hotel. He was held in high respect by his many Indian and English friends.

A Reuter telegram from Shanghai says that Dr. Cawas Lalca was 46 years of age. He was born at Ahmedabad, in Gujrat, and made his preliminary studies in medicine at Bombay. He went to London in 1884, where he took the degree of L.R.C.P. He took the degree of M.D. at Brussels in 1886. He had a large practice in Shanghai, where he was Surgeon-Major and principal medical officer of the Volunteers of the British settlement, and leader of the Parsi community.

#### Royal Medical Benevolent Society of Ireland.

A REGULAR meeting of the Central Committee was held at the Royal College of Surgeons on Wednesday afternoon—Mr. Arthur Benson in the chair.

The Secretary stated that a donation of 20 guineas had been received from Dr. Horne, President of the Royal College of Physicians. The Secretary was instructed to convey to Dr. Horne the best thanks of the Committee for his generous donation.

The Secretary stated that the collection made at the annual dinner of the Irish Medical Association resulted in an addition of £27 7s. to the funds of the Society. A resolution of thanks was unanimously adopted.

Letters were read from Dr. Palmer resigning the post of Hon. Secretary and Treasurer of County Armagh (N.) Branch; from Dr. McKenna resigning the post of Hon. Secretary and Treasurer of County Monaghan Branch, and from Dr. H. G. Molony resigning the post of Joint Secretary and Treasurer of County Limerick Branch. Resolutions of regret were unanimously adopted.

Four urgent applications were considered, and grants amounting to £80 were made, and bills amounting to £50 4s. 10d. were passed for payment.

#### Cholera in Russia.

THERE were 94 fresh cases of cholera on July 1st in St. Petersburg, and 29 deaths. The total number of cases at that date was 607. Five cases of cholera have occurred at Archangelsk.

#### University of Birmingham.

THE following is a list of successful candidates at the June examination:—

I.—Degrees of Bachelor of Medicine and Bachelor of Surgery.—(a) Official.—William F. Haslam and Percival P. Cole. (b) Under Ordinary Regulations.—†Walter C. Blackham, Herbert H. Sampson, Harold C. Terry, Ethel A. Waldron, Kenneth D. Wilkinson.

II.—Fourth Examination for the Degrees of M.B., Ch.B. (Forensic Medicine and Toxicology and Hygiene and Public Health).—Class I.—\*Eric W. Assinder. Class II.—Elizabeth S. Impey, Arthur H. Newton, John L. Ritchie, Cranston Walker. (\*Queen's Scholarship. †Ingleby Scholarship.)

III.—Third Examination for the Degrees of M.B., Ch.B. (Pathology and Bacteriology and Materia Medica and Pharmacy).—Class I.—\*Oscar M. Holden. Class II.—James H. Bampton, Robert B. Coleman (Materia Medica and Pharmacy), Christopher C. C. Court (Pathology and Bacteriology), Evan Davies (Pathology and Bacteriology), Travis Hampson (Pathology and Bacteriology), Charles W. Hayward (Pathology and Bacteriology), Elizabeth S. Impey (Materia Medica and Pharmacy), Charles C. Jones, Douglas N. Macleod (Pathology and Bacteriology), Ronald D. Nelson, Percy A. Newton, Arthur M. Pickup (Materia Medica and Pharmacy), Charles E. Salt, Arthur C. Tibbits. (\*Queen's Scholarship.)

IV.—Second Examination for the Degrees of M.B., Ch.B. (Anatomy and Physiology).—Class II.—George H. Alabaster, Edward Bach, Ralph A. Broderick, Eric F. Buckler, Elsie M. Humpherson, John C. Jones, John B. Lowe, Douglas N. Macleod, Horace C. Nickson, Herbert Sheasby, Charles L. Spackman.

V.—First Examination for the Degrees of M.B., Ch.B. (Chemistry, Physics and Biology).—Class II.—Elizabeth L. Ashby, Robert Ellis, James H. Ritchie, Thomas S. Stafford (Biology). External Candidates.—Koch H. Gill (Chemistry and Biology), Alfred P. Smith.

#### Trinity College, Dublin.

THE following candidates passed the Intermediate Medical Examination during Trinity Term, 1909:—Part I.—John Colgan and Jacobus M. S. Gericke (passed on high marks); Frederick B. M'Carter, Eileen Hewitt, Hubert T. Bates and Robert A. Flood (æq.), James N. Armstrong, Georgina Revington, Robert G. Ball, Dorothy K. Milne, William E. Fetherstonhaugh, Edwin F. O'Connor, Jerome H. Counihan, Jevan H. Powell, Arthur P. Draper and Hugh G. Trayer (æq.), Robert H. C. Lyons, Cecil Rutherford, William Frier, Oswald V. Burrows, James H. Grove-White, Richard L. Grandy, Antonie C. Redelinghuys, Humphry L. Blackley, Hugh E. Williams, Frederick A. Burke.

Purser Medal in Institutes of Medicine.—Jacobus M. S. Gericke.

Medical Travelling Prize and Banks Medal.—Albert Stals.

Banks Prize.—John L. Phibbs.

The M.Ch. Degree was bestowed on J. Singleton Darling, and the M. Dent. Sci. Degree on Ernest S. Friel.

The following passed the Final Examination in Medicine.—Part II.—Surgery.—Thomas A. Hughes, Ralph T. St. J. Brooks, David Duff, and Eric J. Powell (passed on high marks), John D. Kernan, George E. Craig, Edwin B. Bate and Frederick R. Sayers (æq.), David J. Miller, Frederick G. Anderson, Charles G. S. Baronsfeather, James P. S. Dunn, Wellesley R. Allen, Denis J. Stokes.

MR. H. MORRISTON DAVIES, M.C. (Cantab), has been appointed Assistant Surgeon to University College Hospital, London.

## NOTICES TO CORRESPONDENTS, &c.

OUR CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

### SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12. Messrs. Dawson and Sons are our special agents for Canada.

### ADVERTISEMENTS.

FOR ONE INSERTION:—Whole Page, £5; Half Page, £3 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 52 insertions at £3, and pro rata for smaller spaces.

Small announcements of Practices, Assistances, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

ORIGINAL ARTICLES OR LETTERS intended for publication should be written on one side of the paper only and must be authenticated with the name and address of the writer, not necessarily for publication but as evidence of identity.

CONTRIBUTORS are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland to the Dublin office, in order to save time in reforwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

MR. R. S. SAMUELS.—There is a new edition of the book announced as in the press. We would advise your waiting for this; the work is an excellent one, and we can recommend it.

A CORRESPONDENT of the *Manchester Guardian*, writing of "the Chinese system of paying your doctor to keep you well," says that he came across the custom when living in St. Petersburg thirty years ago. The weak spot in this, he remarks, as in the club-doctor system, is the doubt who is to be the judge whether a man is well or ill?

AMBOCEPTOR.—The article in question is proprietary, and we presume the author of the paper dealing with it has convinced himself of its therapeutic value before committing his views to print. If there is to be any rule on the subject, it must clearly apply to members of one College as well as of another. Unwritten rules are apt at times to be applied unequally. It is the old proverb of one man not being able to look over a fence, while another may steal a horse.

DR. T. D. L.—Proof will be sent to you in due course.

MR. F. DIXON has sent us a letter, too long to publish, in answer to Mr. Sers' assertions that there is a money basis to the Christian Science publications. Mr. Dixon asks if religious and medical books are distributed gratis. The cases are not analogous with the Christian Science publications, inasmuch as the latter advocate a special treatment, which is in the hands of a small knot of persons—in other words, there is a not indistinct suggestion of the "puff oblique" in this matter. Mr. Dixon has not, in our opinion, traversed the criticism that so-called "Christian Science" healing has a money-making basis.

## Meetings of the Societies, Lectures, &c.

### WEDNESDAY, JULY 7TH.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.)—4 p.m.: Mr. T. Walker: Clinique (Surgical). 5.15 p.m.: Lecture: Dr. A. F. Tredgold: Feeble-minded Children.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Prince of Wales's General Hospital, Tottenham, N.)—Clinics: 2.30 p.m.: Medical Out-patient (Dr. T. R. Whipham); Skin (Dr. G. N. Meachen); Eye (Mr. R. P. Brooks).

### THURSDAY, JULY 8TH.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.)—4 p.m.: Sir Jonathan Hutchinson: Clinique (Surgical). 5.15 p.m.: Lecture: Dr. J. Collier: Acute Polyneuritis and Landry's Paralysis (illustrated by cases).

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Prince of Wales's General Hospital, Tottenham, N.)—2.30 p.m.: Gynecological Operations (Dr. A. E. Giles). Clinics: Medical Out-patient (Dr. A. J. Whiting); Surgical (Mr. H. W. Carson); X-Rays. (3 p.m.: Medical In-patient (Dr. G. F. Chappell).

### FRIDAY, JULY 9TH.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM (11 Chandos Street, Cavendish Square, W.)—8 p.m.: Card Exhibit by Dr. F. W. Edridge-Green of Spectroscope for Testing Colour Perception. Mr. A. Lawson and Mr. M. Davidson: A Preliminary Note of the Treatment of Eye Disease by Radium. Presentation of the Nettleship Medal to Mr. Nettleship. The Annual Meeting of the Society will be held immediately after the Ordinary Meeting.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.)—4 p.m.: Mr. R. E. Bickerton: Clinique (Eye).

CENTRAL LONDON THROAT AND EAR HOSPITAL (Gray's Inn Road, W.C.)—3.45 p.m.: Lecture: Dr. D. McKenzie: External Ear.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Prince of Wales's General Hospital, Tottenham, N.)—10 a.m.: Clinic: Surgical Out-patient (Mr. H. Evans). 2.30 p.m.: Operations (Mr. W. Edmunds). Clinics: Medical Out-patient (Dr. A. G. Auld); Eye (Mr. R. P. Brooks). 3 p.m.: Medical In-patient (Dr. R. M. Leslie). 4.30 p.m.: Lecture: Mr. R. P. Brooks: Subconjunctival Injections in the Treatment of Eye Disease.

## Appointments.

CARRUTHERS, GEORGE, M.D., O.M. McGill, Clinical Assistant to the Chelsea Hospital for Women.  
COX, E. HARVEY, M.B., Ch.B. Manch., Honorary Surgeon to the Rochdale Infirmary.  
DOHERTY, D., L.R.C.P. and S. Edin., L.F.P.S. Glasg., Certifying Surgeon under the Factory and Workshop Act for the Clonmany District of the county of Donegal.  
FALCONER, ARTHUR WELLESLEY, Assistant Anaesthetist to the Aberdeen Royal Infirmary.  
HEGARTY, J., M.D., M.S.Q.U.I. Certifying Surgeon under the Factory and Workshop Act for the Cloonbur District of the county of Galway.  
MCLEWEN, H. F., M.D. Halifax, Clinical Assistant to the Chelsea Hospital for Women.  
MARTIN, E. K., M.B., B.S. Lond., M.R.C.S., L.R.C.P. Lond., House Physician at University College Hospital.  
O'HART, P., M.B., B.S.E.U.I., Certifying Surgeon under the Factory and Workshop Act for the Carney District of the county of Sligo.  
PARRY, JOHN R., M.B. Tor., Clinical Assistant to the Chelsea Hospital for Women.  
STERN, ROBERT HUNTER, M.D. Lond., Professor of Psychological Medicine at King's College.  
TASKEE, H. L., M.R.C.S., L.R.C.P. Lond., Obstetric Assistant to University College Hospital.  
TRICHMANN, OSKAR, F.R.C.S. Eng., Clinical Assistant to the Chelsea Hospital for Women.

## Vacancies.

West Riding Asylum, Wadsley, near Sheffield.—Fifth Assistant Medical Officer. Salary £140 per annum, with board, etc. Applications to the Medical Superintendent.  
Queen Alexandra Sanatorium, Davos Platz, Switzerland.—Resident Medical Superintendent. Salary £200 per annum, with board and residence. Applications to the Joint Hon. Secs. Wm. Ewart, M.D., 31, Upper Brook Street, London, W. Worcester County and City Asylum, Powick.—Third Assistant Medical Officer. Salary £140 per annum, all found. Applications to the Superintendent.  
Royal South Hants and Southampton Hospital.—House Physician. Salary £100 per annum, with rooms, board, and washing. Applications to T. A. Fisher-Hall, Secretary.  
Victoria Hospital, Burnley.—Resident Medical Officer. Salary £100 per annum, with residence, board, and washing. Applications to F. A. Hargreaves, 7, Grimshaw Street.  
Whitehaven and West Cumberland Infirmary.—Resident House Surgeon. Salary £120 per year, with board and lodging. Applications to W. H. Sands, Secretary.  
Administrative County of Somerset.—County Medical Officer of Health. Salary £700 a year. Applications to G. I. Simey, Clerk of the Somerset County Council.  
Berks County Asylum, Wallingford.—Second Assistant Medical Officer. Salary £150 per annum, with board, furnished apartments, attendance, etc. Applications to Medical Superintendent.  
Northern Infirmary.—House Surgeon. Salary £100 per annum, with board, etc. Applications to Mr. Duncan Shaw, W.S., Inverness.

## Births.

ADDISON.—On June 28th, at Mahe, Seychelles, the wife of J. B. Addison, M.R.C.S., L.R.C.P., Colonial Medical Service, of a son.  
COOPER.—On June 29th, at 29 Eccleston Street, Eaton Square, London, the wife of Austin Cooper, M.D., of a daughter.  
JOSELYNE.—On July 1st, at Kingsclere, Hants, the wife of F. P. Joseplyne, M.D., of a son.  
KILLICK.—On June 29th, at Trinity House, Maidstone the wife of Charles Killick, M.D., F.R.C.S., of a daughter.

## Marriages.

HUMPHRY-DREWITT.—On July 1st, at the Parish Church, Oving, Sussex, Philip Reginald Humphry, M.R.C.S., L.R.C.P., eldest son of Dr. and Mrs. Humphry, of St. John's Street, Chichester, to Kathleen Ellen, younger daughter of Mr. and Mrs. C. J. Drewitt, of Drayton House, Chichester.

## Deaths.

HAZELTON.—On June 29th, at 83 Oxford Gardens, London, Robert Hazelton, F.R.C.S.I., in his 85th year.  
ORMEROD.—On June 29th, at 51 Brunswick Place, Hove, Brighton, Maria, widow of Edward Latham Ormerod, M.D., F.R.S., of Brighton, aged 77.  
WOLFENDEN.—On July 1st, at Eastbourne, Jessie Stuart, wife of Richard Norris Wolfenden, M.D., of the Grange, Sidcup, and youngest daughter of the late James Jardine, of Alderley Edge, Cheshire.

No. 2.

## NOTES AND COMMENTS.

### Constructive Murder.

THERE was tried at the West Riding Assizes, last week, a Mrs. Lyle, sixty years of age, who for many years had carried on the practice of abortion-mongering. A large number of women came forward and gave evidence against her, saying that they had been operated on to procure abortion. The charge in this case was one of murder, a wretched woman on whom Mrs. Lyle had operated, having died of septic peritonitis. In a dying declaration the poor creature had stated all the facts of her visit in the clearest possible language. There was absolutely no shadow of doubt all through that the prisoner not only was guilty of the particular crime she was charged with, but that she was an old, deliberate and habitual offender. Counsel for the defence made no attempt to dispute the evidence and called no witnesses of any kind, but he concentrated all his energies in getting the crime reduced from murder to manslaughter, and in this he was successful, the prisoner being eventually awarded ten years' penal servitude. If a jury refuses to convict a woman of murder under circumstances such as these, it may be taken that the slaying of a woman through performing an operation for abortion has come to rank with infanticide, namely, as a form of murder which is so lightly regarded that prisoners convicted of it know they run no risk to their own lives. Such an attitude, as regards abortion, is deplorable, for we have little doubt that if the death penalty were carried out in a few heinous cases, the crime would be recognised as not worth the candle.

### A Modern Cynic.

THE more one sees and hears of the actions of the anti-vivisectionists, the more one marvels that human beings, who fill an ordinary part in human society, can be so utterly devoid of any sense of common decency. A kind of insane mod-ideism seems to possess them, till every action, the simplest and the most elementary, of those they hate, is invested with a halo of villainy. It is hardly possible to understand how a barrister and a Member of Parliament, such as Mr. Ellis Griffith is, can have been so utterly lacking in all sense of proportion as to propound to the Home Secretary last week such a question as he put to Mr. Gladstone. At the *conversazione* of the Royal Society, in May, Dr. Waller showed the variation in electrical potentials which take place with the pulsations of the heart, by the very simple experiment of standing a dog in a series of electric cells placed in circuit with a galvanometer. The needle shows a series of constant changes with the beats of the heart, a fact which may have, and, indeed, is already claimed to have, a considerable bearing on cardio-therapeutics. But

whether immediately useful or not, this simple experiment has a high suggestive value, for anything in the nature of electro-therapeutics in heart affections has not yet been thought of.

### The Paddling of the Bull-Dog.

BUT Mr. Griffith has for some years past endeavoured to achieve notoriety by championing the cause of dogs in the House of Commons, knowing that most of the people's representatives, like the people themselves, are personally attached to dogs. Still, it is possible to overdo a rôle, and we sincerely congratulate Mr. Gladstone in having disposed, once and for all, of Mr. Griffith's inflated pretensions. Mr. Griffith asked the Home Secretary whether at this demonstration Dr. Waller had not "secured" the dog—a bull-dog, by-the-bye—by a leather strap with sharp nails, immersed his feet in glass jars, which jars were connected with galvanometers; and whether Dr. Waller was licensed to perform such an experiment; whether Burlington House was licensed for such experiments; and, finally, whether any action was being taken in the matter. Even Mr. Gladstone's official propriety was not proof against such a glaring misrepresentation of facts, especially as he had himself seen Dr. Waller and played with the bull-dog. He said that the "leather strap with sharp nails" was an ordinary dog-collar with brass studs; that the dog stood in ordinary salt solution; that the dog was neither tied nor muzzled; and that the experiment was absolutely painless, in fact, if the honourable member had paddled in the sea he would have experienced the same sensation. Roused by the laughter which greeted these sallies, Mr. Griffith and two others of the sillier type of anti-vivisectionists tried to save the faces of their prompters, but the hollowness of the whole performance caught the imagination of the House, and we can only pray that a few more of these spiteful and infantile performances may be given, so that people may realise the real character of the anti-vivisection movement.

### The Dog as Servant to Man.

WE are not at all inclined to let this question of the dog go by default. Mr. Ellis Griffith brings himself before the public about once every session of Parliament by presenting a huge petition against dogs being used for the purposes of scientific research. As dog-lovers, we are all in favour, we need hardly say, of decent and proper treatment, and if Mr. Griffith, instead of endeavouring to prevent earnest and truth-seeking men to forward the interests of their fellows by experiments on dogs, tried to stop the painful exhibition which maudlin women make of themselves by coddling these noble creatures in fine linen and false teeth, he would be serving his species far

better. The sympathy it is sought to raise in favour of dogs is purely artificial sympathy, and we would specially commend to his notice the admirable pamphlet by Professor Starling, issued by the Research Defence Society, "On the Use of Dogs in Scientific Experiments." Professor Starling shows that, apart from subsidiary reasons, the dog is an indispensable animal for experiment in modern academic scientific laboratories, and for this contention he advances five reasons. Apart from all others, let us concentrate on his number five. Here he shows that Pawlow's work on digestion carried out in dogs—all perfectly painless—has practically revolutionised our knowledge of digestion, and consequently our treatment of gastric disorders. It is not yet ten years since "indigestion" was regarded as a simple condition, and was treated on stock lines. Nowadays a physician, under the influence of Pawlow's conclusions, regards indigestion as a complex condition, and it is on his knowledge of the factors which produce the disease that he is able to prescribe and apply the proper treatment. Without the dog, which, like man, is almost an omnivorous animal, these new and most important lessons could never have been learned. We can hardly expect that Mr. Ellis Griffith will be impartial enough to read Professor Starling's pamphlet, and still less can we hope that he will be sufficiently fair to do justice to its conclusions, but we may perhaps be allowed to express the hope that the Government will recognise the type of mind they have to deal with, and that they will not promote the honourable Member for Anglesea to a judicial position where qualities of head and of character are specially needed for the due administration of justice.

**Holloway's Pills.** THE estate of the late Mr. Henry Driver-Holloway, the proprietor of "Holloway's Pills," has been sworn at £42,681, and, after making various bequests, the residue is

left to his widow, with remainder to his children. This sum compares favourably with the sum of Mr. Thomas Holloway, who left estate valued for probate at £596,335, much of which, as is well known, went to the foundation of Virginia Water Asylum and the Holloway College for Ladies. There would seem to be a certain significance in these facts. Holloway's pills, presumably, are the same as ever they were, and yet the revenue derived from them must have fallen substantially, one would imagine, to judge from these amounts. If the pills have not lost their magic, we must seek another reason. We fancy it is to be found in the less publicity given to them than was the case thirty years or so ago. While we abhor the whole of patent medicines as subversive of the morality, both of the proprietors and of the organs they advertise in, and also of the public health, we in candour admit that some of the proprietors do seem to shrink from the unblushing, lying type of advertisement which fill the sheets of, alas, almost every journal in the land. Holloway's pills do not seem to have emulated the later Transatlantic type of blatant falsehood, and the receipts would appear from that reason to have dwindled. In the reports of public companies trading as patent medicine vendors, it is always explained at the annual meetings that the enormous amounts spent on advertisement are necessary to keep the business going at all, and we have no difficulty in seeing that practically the whole assets of such companies is goodwill represented by the money spent on advertisement. The subservience of the press to this influence is not the least of the influences that tempt staunch democrats to despair of their faith.

### THE PHYSICAL SIDE OF PUBLIC SCHOOL LIFE.

It is difficult to exaggerate the importance of the bearing of physical exercise upon school life. Indeed, it may be said broadly that the national physique of the coming generation may be made or marred by the wisdom or otherwise with which this important matter is handled. In the case of public schools, things have until recently been permitted to take their own course, with results that, generally speaking, have been on the whole satisfactory. In this struggle for survival the fittest have doubtless come out unscathed, but, on the other hand, it is absolutely certain that the weak have gone to the wall, and many a physically defective life has been ruined before the rigorous test of a public school environment. These facts have at length been recognised by medical science, and, later, by the Legislature, with the result that the whole question is being dealt with by competent authorities. Pointed attention was drawn to the matter by the appearance of a letter signed by five eminent medical men in the *Times* of February 8th last. In that communication they condemned school and cross-country races exceeding one mile in distance as unsuitable for boys under the age of nineteen years. They argued that the continued strain involved in that special form of exertion was apt to cause permanent injury to the heart and other organs. Their challenge was naturally taken up forthwith by the Medical Officers of Schools' Association, who have brought together and published a mass of facts and conclusions in a pamphlet with the title, "School Athletics and Boys' Races." At a meeting of the Association held on March 5th a series of important resolutions were adopted, and these we propose to quote briefly, with a running commentary. Their first conclusion that age is not the best criterion of physical fitness seems more or less self-evident, in spite of the arbitrary standard taken by the "five eminent London doctors." Most men familiar with public schools will recall boys who at various ages have shown remarkable aptness for some particular form of continuous physical exertion, it may be long distance swimming or long diving, the mile race or the cross-country run, or of rowing, cycling, walking, and so on. In some way a particular lad has the perfect balance of physique, lungs, heart, muscles and temperament that fits him for excellence in some peculiar branch of sustained athletics. But it would be impossible to imagine that such excellence could be attained, or, at any rate, maintained, for more than a brief space of time by any boy who was physically unfit. And this reflection brings us by easy stages to the unanimous approval by the Association of the principle of subjecting boys on entering a public school to thorough medical examination. Without that preliminary test it is impossible to exclude boys who are physically unfitted for the strain of violent athletic exercises. To expose, say, a hundred school-boys who have not undergone a medical examination, to a twelve or fifteen-mile cross-country run would be infallibly to court disaster in a certain percentage of cases. The medical officers hold, it appears to us justly, that the

quarter-mile is one of the most exhausting of all races. We were hardly prepared for the conclusion that hockey is more exhausting than football, and that girls playing hockey should be subjected to periodical medical examination. Our readers will find no difficulty in endorsing the warning against active exercise immediately after a meal, or against the risk of over-exertion during convalescence. While we agree with the desirability of carefully inquiring into the matter of school athletics, the main thing seems to be in the exclusion of the physically unfit at the outset, and, if necessary, at later stages of school life. Athletics, like tea, tobacco, alcohol, food, and many other things, can be indulged in by the strong to an extent that would be highly, and perhaps permanently, injurious to those less physically perfect. It seems probable that the athletic exercises of school and college life rarely injure the strong, witness the after career of athletes who have pulled in the 'Varsity boat-race. Exercise of some kind is necessary for all public school-boys, whether strong or weak, and the question of degree is one that must be left to medical supervision. In this respect a valuable suggestion was made by Sir Lauder Brunton, namely, that greater importance should be attached to systematic exercises, as opposed to athletic competitions. That there is need for propaganda such as those published by the Association we are sharply reminded by the fact that, of thirty-eight representative schools furnishing information, only eleven examine the boys on entry to the school. That is to say, in twenty-seven public schools a boy with some valvular lesion of the heart may join in some violent athletic sport which may shorten or destroy his life. The responsibility is one from which it may be imagined most school authorities would shrink, did they but realise the facts of the situation. Yet the principle of medical inspection of school children undoubtedly represents one of the greatest practical advances in modern times towards the safeguarding and the raising of the standard of our national physique.

### CURRENT TOPICS.

#### The Presidency of the Royal College of Surgeons, England.

THE annual election of President of the Royal College of Surgeons always takes place at the first Council meeting after the election of the new members to the Council, and the choice this year has fallen upon Mr. H. T. Butlin, one of the consulting surgeons to St. Bartholomew's Hospital. Mr. Butlin, of course, has high claims to the honoured position to which he has attained. He became a Fellow of the College as long ago as December, 1871, two years before the retiring President, Sir Henry Morris; he is not, however, the senior Fellow on the Council, the "father" of that august body being Mr. Clement Lucas, who has just been re-elected to a further term of eight years' office. Mr. Lucas is six months senior to the new President, in the date of Fellowship. The two members of the Council who have been chosen Vice-Presidents are Mr. Pearce Gould and Mr. Lucas. The vice-presidencies, it need scarcely be pointed out, carry with their office none of the special honours

which belong to the Presidential chair, nor can they be regarded as stepping-stones to the office of President, although it is usual for a President to have previously filled one of these junior posts. At one time a strong feeling prevailed among many of the Fellows that the election of President should be added to the privileges which belong to the Fellowship, and efforts were made to urge this reform upon the Council, the main contention being that at the sister college, the Royal College of Physicians, the Fellows possess the right of electing their President. Naturally, however, the Council then existing were unable to comprehend the force of the argument, and declined to consider the proposal. The weak point, obviously, on the side of the reformers was that they were unable to show any evidence which could be said to render the innovation necessary. And, as a matter of fact, it is common knowledge that these elections within the Council itself are most jealously guarded. Not only are the interests of the College to be considered, but weight has to be given to the maintenance of the reputation of the surgical profession in this country, of which the Presidency of the Royal College of Surgeons represents the Blue Ribbon. In view, therefore, of past experience in these elections, it is doubtful whether, if the Fellows had had the right of election, they would have done as well as the Council. Of course, similar questions of expediency obtain in the election of the President of the Royal College of Physicians, and these questions the Fellows decide for themselves; but perhaps there is more cohesion, more organisation, among the Fellows of the Royal College of Physicians than is the case among the Fellows at the College in Lincoln's Inn Fields.

#### Death Certification.

AN unpleasant incident which occurred at Newcastle last week throws into strong relief the unsatisfactory state of the law regarding death certification. A butcher, named Robson, a man of seventy years of age, died suddenly of cardiac disease. He had previously been attended by Dr. Colly for that complaint, which was accompanied with attacks of angina pectoris. A month after Dr. Colly's last attendance, news was brought him of Mr. Robson's death, which had occurred under every circumstance pointing to angina pectoris. At first Dr. Colly was not sure which of his patients Mr. Robson was, as, since attending him, he had seen no less than fifteen persons of that name. On being shown his photograph, however, he recognised which of the sixteen Robsons was the one, and, in accordance with his statutory duty, he certified that, to the best of his knowledge and belief, the patient had died of angina pectoris. The coroner, however, ordered an inquest, and gave the post-mortem to Dr. W. J. Wilson, who found that death was due to heart failure following on disease of the organ. The jury found in accordance with this view, and further expressed the opinion that Dr. Colly had given a certificate on evidence insufficient to warrant it, as he had not seen the patient for a month, and not at all after his death, a letter from Dr. Colly, which was read at the adjourned inquest, notwithstanding. This letter stated cogently the law of death-certification, and pointed out that he (Dr. Colly) was under a statutory

obligation to certify "to the best of his knowledge and belief," as he had no reasonable doubt as to the cause of death. Nevertheless, the jury passed the above-mentioned censure, which, in our view, was an unmerited slight on a practitioner, and was due to the jury—and probably the coroner—being unaware of how the law really stands. The latter, of course, compels a man to certify, and nothing is said about reporting to the coroner; it is assumed that the latter official will get his information from the district registrar, and act accordingly. No medical man is bound, or even asked, to supply information to the coroner; the coroner's duty, in the strict legal sense, is confined to his work at the inquest itself, whereas the medical man has no option, for he has to give a certificate; the coroner's function is merely to decide on an inquest if he thinks the death due to other than natural causes. By the doctor, in his strictly legal position, it is necessary that a certificate *shall* be given, and the future is left to look after itself! We consider that Dr. Colly was treated both illegally and unworthily by the jury in the case under notice, and the coroner should have directed them as to their responsibilities.

#### Dirty Dublin.

THE recent dry weather has again brought emphatically to the notice of the citizens of Dublin the dirty condition of the streets. On many occasions we have had to notice this nuisance, but we cannot as yet congratulate the Corporation on putting their streets into a cleanly and respectable condition. Horse-droppings still lie unswept and ungathered in the streets, to be beaten into dust by wheels and hoofs, and then carried by the wind to the sleeping and living rooms of the unfortunate and over-taxed ratepayers. On a previous occasion, when we commented on this disgusting condition of affairs, the Corporation referred our comments to the Cleansing Committee, which solemnly reported in reply. The Committee stated that our allegations must be baseless, as more tons of street sweepings were removed per mile of street in Dublin than in certain other cities. This may be quite true. The streets of Dublin are unusually wide, and are worse paved than those of any other city we know. In addition, the "street sweepings" in Dublin are to a great extent the scavengings of the city, for in the poorer quarters refuse is constantly thrown on the streets, to be removed or not as the Corporation employees think fit. We had hoped that, though finding themselves "not guilty," in reply to our charges, the Cleansing Committee might have silently resolved not to do it again. It appears we were wrong, and the Dublin ratepayer still has the pleasure of paying for work which is not done.

#### The Proposed Tax on Petrol.

THE Chancellor of the Exchequer received a deputation of medical men recently on the subject of the proposed taxation of petrol and motor-cars. The deputation urged that medical motorists should receive at least the same relief as that granted to those using motor-cars for commercial purposes. The Chancellor replied that he was convinced of the justice of so doing, so far as the rebate on

petrol was concerned. His difficulty was as to the practicability of carrying out the concession. The deputation might, however, take it that he would make the alteration asked for. This is a very important concession, so far as medical men are concerned, and we trust that it will be satisfactorily carried into effect. Medical motorists should not regard their point as obtained until it is part of the Bill. Even then it will be necessary to see that both it and the rebate on motor-car taxation are granted on such terms as to be practicable. If the rebates are only granted on the condition that a car is never to be diverted from the path of strict duty and attendance on patients, they will obviously be intended only for the eye, as under such conditions all rebate might be lost because a car owner once turned off his road to accommodate a friend. The medical owner should be obliged to state that he had purchased his car for the purposes of his profession, and that he so used it, and, once this had been accepted, hampering restrictions as to its further use could only result in rendering the concession valueless.

#### Medical Men and Public Speech.

IN speaking from the chair, when giving away the prizes at St. Thomas's Hospital recently, Mr. Alfred Lyttleton made the curious statement that medical men had the best opportunity of learning the art of speaking, because they always had attentive audiences in their patients, whereas politicians and lawyers had often to speak to impatient audiences and unsympathetic or irascible judges. We will not stay to inquire which condition fits a man for public speaking best, that of having sympathetic or unsympathetic listeners, for we conceive the answer to be precisely the opposite of what Mr. Lyttleton said, for he who addresses, for the first time, an unsympathetic audience, when accustomed to adulation for his oratory, generally receives a rude shock. But it is not a little odd that Mr. Lyttleton should think doctors have opportunities of learning the art of speaking superior to those of politicians and lawyers, for we should have thought it a platitude to say that the latter speak in public almost habitually, whereas the doctor rarely raises his voice, except at a cricket supper or old school dinner. One fact which undoubtedly delays many of the pressing reforms in the profession is the dislike medical men have to appear on public platforms, and their inability to make a good and lasting impression when they do so. It is the essence of a clergyman's profession to be glib if he cannot be fluent, and a barrister who cannot speak well and think readily "on his legs" will do but little good in the courts; to a politician such qualities are the breath of life. Some medical men are very good speakers, if not orators. Names will occur to everyone, but we may just cite the late Sir Charles Hutchinson in passing, but they are so by natural gift, and not by training. The inability of medical men to debate or speak tellingly in public when pitted against lawyers and politicians must have struck everyone with much experience of public meetings. The drawback is a real one, for people are apt to assume that the lawyer or politician has more behind him in the way of a case than the doctor. As a rule, it is quite the opposite, only the doctor has not the

faculty of presenting his view to the best advantage. And so medical reform hangs fire.

### The German Birth-Rate.

LIVING as we do in days of Teutono-phobia, when a large section of the population seem to have lost faith in the British race and approves of nothing that is not made in Germany, it does no harm for people who have faith in John Bull, and are not frightened into believing every balloon to contain emissaries from the Kaiser, to examine some of the claims made against their own country of degeneracy and loss of manhood. An interesting example of such inquiry is to look at the German vital statistics which are published this year in a separate volume on the movements of the population for 1907, with especial attention to the birth-rate. These figures show that the birth-rate fell to 33.2 per 1,000 inhabitants, as compared with 34.08 in 1906. The death-rate fell to 18.98, as compared with 19.20 in 1906. The excess of births over deaths was 882.624, as compared with 910,275 in 1906. The excess, however, of births over deaths was greater in 1907 than in any previous year except 1906 and 1902 (902,243). The decline in the birth-rate, which stood at 41.64 in 1877, 38.33 in 1887, and 37.17 in 1897, as compared with 33.2 in 1907, is now attributed to a falling-off in the number of births in every part of the Empire except Westphalia, and in Westphalia the number of births is not quite keeping pace with the total growth of population. The decrease in number of births in the whole Empire in 1907 was 23,766, or 1.1 per cent. In Saxony the decrease was 3 per cent., and East Prussia, West Prussia, and Pomerania show about the same percentage. A falling birth-rate is assumed by our economists to be a sign of national decay; so that it seems the great Armageddon (when it comes) will be a tussle between degenerates. Surely there are acmes of folly both in 'phobias and in economics.

## PERSONAL.

HIS MAJESTY THE KING, during his recent visit to Gloucester, gave permission for the title "Royal" to be prefixed henceforward to the name of the Gloucester General Infirmary, "in recognition of the admirable work done by those responsible for its management, and the devoted and successful efforts of its staff in the prevention and alleviation of human suffering."

THE opening ceremony of the new Manchester Royal Infirmary took place on July 6th, when the buildings were declared open by His Majesty the King, who was accompanied by Queen Alexandra.

HER MAJESTY THE QUEEN has given her approval of the proposed endowment of a bed in the York County Hospital in memory of the late Canon Fleming, and endorsed this with a personal donation.

THE Prince and Princess of Wales, the Duke and Duchess of Connaught, and Princess Christian gave their patronage to the Carnival, held on July 1st, at the Crystal Palace, in aid of the fund for the removal of King's College Hospital to South London.

LADY TATE has presented £1,000 to endow a bed in the Chelsea Hospital for Women.

THE retirement is announced from the post as Senior Surgeon to the Cancer Hospital, of Mr. Frederick Bowreman Jessett, F.R.C.S.

DR. J. S. PEARSON and Dr. J. C. Murphy have been confirmed in the offices of Medical Officer, West African Medical Service, Sierra Leone.

THE London Hospital Medical College Endowment Fund has received a gift of £2,000 through Dr. Luther Martin, an old student of the hospital.

DR. A. DE L. ROBINSON, who has been appointed Principal Assistant Medical Officer of Health, Colombo, Ceylon, has arrived in the Colony and assumed duty.

THE annual general meeting of the Asylum Workers' Association was held yesterday, at 3 p.m., at the Medical Society's House. Sir William Collins, M.P., presided.

SURG.-LIEUT.-COL. ROWLAND HILL COOMBS, of the 3rd Battalion Bedfordshire Regiment (Special Reserve), has been appointed a Deputy-Lieutenant for the County of Bedford.

DR. GIBBON FITZGIBBON, formerly Assistant Master at the Rotunda Hospital, has been appointed Gynaecologist to Mercer's Hospital, Dublin, in the place of Dr. Glenn, who has resigned.

THE sixty-eighth annual meeting of the Medico-Psychological Association of Great Britain and Ireland will be opened on the morning of Thursday, July 22nd, at the West Riding Asylum, Wakefield.

THE ceremony of laying the foundation stone of the out-patients' department of the Liverpool Royal Infirmary was performed on the 6th inst. by the Earl of Derby, G.C.V.O., C.B.

DR. A. E. IRELAND, Government Medical Officer, Grand Turk, West Indies, has been transferred to Fiji as Medical Officer of Health, and will be succeeded at Grand Turk by Dr. T. R. Robertson, District Commissioner and Medical Officer, Caicos Islands.

THE Forfarshire Medical Association held their annual dinner in the Royal Hotel, Forfar, on July 2nd. The chair was occupied by Dr. Leishman, Brechin, vice-president of the Association, and the croupier was Dr. Pirie, Dundee.

THE offices of Commissioner and Medical Officer of the Virgin Islands, which have been amalgamated for the past thirteen years, have now been separated on the transfer of Dr. R. S. Earl to the Falkland Islands, and Dr. T. Leitch Wilson becomes Medical Officer.

DR. W. WYNN WESTCOTT, J.P., coroner for North-East London, has recently been elected President of the Coroners' Society of England and Wales, and Mr. Walter Schröder, Deputy Coroner for Central London, has been reappointed Honorary Secretary of the society.

MR. HENRY T. BUTLIN, D.C.L., F.R.C.S., was elected on Thursday last to succeed Sir Henry Morris, Bart., as President of the Royal College of Surgeons of England; at the same meeting of the Council Mr. A. Pearce Gould and Mr. R. Clement Lucas were elected Vice-Presidents.

PROFESSOR ERNEST W. WHITE, M.B., has been elected Emeritus Professor of King's College, London, on his retirement, after twenty years' service, from the professorship of psychological medicine. The vacancy thus caused has been filled by the appointment of Dr. Robert Hunter Steen.

SIR ALAN REEVE MANBY, M.V.O., M.D., who has been appointed a Physician Extraordinary to the King, was formerly Surgeon-Apothecary to His Majesty's household at Sandringham, and to the Prince of Wales's household. He was the medical attendant of the Prince of Wales during his Colonial tour in 1901.

THE annual luncheon of the Continental Anglo-American Medical Society will be held on Thursday, July 29th, at Belfast, during the annual meeting of the British Medical Association. Members intending to be present should communicate with Dr. C. G. Jarvis, the hon. secretary, 81 Boulevard Malesherbes, Paris.

# A CLINICAL LECTURE

ON

## DIGITALIS AND DIGITALINE; WITH SPECIAL REFERENCE TO THEIR USES AND MODES OF ADMINISTRATION.

By PROFESSOR HENRI HUCHARD, M.D.,

Physician to the Paris Hospitals.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

It is often asserted that crystallised digitaline is a dangerous drug because, although extremely powerful, it is not diuretic, and we are therefore urged to give the preference to digitalis in the form of a maceration or infusion of the leaves. It is now upwards of eighteen years ago since I first challenged this statement, and brought evidence before the Therapeutical Society to show that digitaline was really a diuretic, and two years later I showed at the Hospitals Society that it might be employed with advantage in renal affections, adding that digitaline was in reality less dangerous than digitalis.

We know, as a matter of fact, that samples of digitalis gathered in England, Scotland and America differ greatly in the proportion of active principles therein contained. Lauder Brunton long since showed that the same holds good of Indian hemp and certain other plants, the properties whereof vary within wide limits according to the climate, &c. As long ago as 1896 I pointed out that digitalis obtained from the Vosges is far more active than that growing in Auvergne or Brittany, and that even in the same locality—the Vosges or the Morvan, for instance—specimens of digitalis growing within a few hundred yards of each other varied in their properties according to the soil, exposure to sunlight, &c. Then, too, there are good years and bad years for digitalis, just as in the case of wine, and atmospheric influences may greatly reduce the proportion of active principles, while some samples of digitalis are proportionally richer in digitoxin and digitaline than in crystallised digitaline, which fact further explains their variability of action. The roots, stems, petioles and veins contain little or no active principle, which, on the other hand, is present in abundance in the seeds, and especially in the second years' leaves, gathered in June before flowering. Then, too, the leaves are often confounded with those of borage, comfrey and mullein, and still more frequently with those of *Coniza squarrosa*. Cultivated digitalis is almost inert, and even properly-prepared leaves require to be protected against light and damp, otherwise they lose their properties.

How can we hope to obtain a definite uniform product under such variable and multiple conditions? This enables us to understand the extraordinary difference in the doses recommended by various authors. In Edinburgh half a fluid ounce of infusion of the leaves seems to be well borne, and Petrescu used to give 3 or 4 drachms of the leaves in an infusion in the treatment of pneumonia, while in London an infusion of 60 to 80 grains caused merely a little gastric disturbance, yet in France we rarely venture to exceed 10 to 15 grains. The difference can only be explained by variations in the activity of the plant gathered in these countries respectively. Uncertainty as to the nature of a drug begets hesitation on the minds of the therapist. Let us take, for instance, a sample of digitalis improperly dealt with, so that the leaves which, under ordinary circumstances, would represent a milligramme of digitaline, each

gramme only contain a fraction of that amount. Under these circumstances, the inactivity of the drug will be attributed to advanced degeneration of the myocardium, whereas it is the drug that should be incriminated. Let us go a step further and imagine that, on the strength of our experience of the innocuousness of an almost inert sample of digitalis, we prescribe similar doses in another case. This time we happen to alight upon a normal preparation, in which event our patient will be exposed to the risk of poisoning, in spite of the same dose having been given.

The conclusion to be drawn from what precedes is that we ought to give the preference to a product which has a well-defined, and therefore invariable, chemical composition, with consequent uniformity of therapeutical action—viz., crystallised digitaline.

Digitaline is insoluble in water and digitalis is slow in its action, is eliminated very gradually, and tends to accumulate in the organism. We are asked to regard these characteristics as so many defects, but I maintain, on the contrary, that they are qualities; indeed, without them digitalis would be comparatively valueless.

To begin with, its action is not as slow as we are asked to believe, and we must distinguish between the cardiac and the diuretic actions. The cardiac effect is rapid, being manifested in from a quarter to half an hour, or an hour at the outside, as will be seen in cases of paroxysmal tachycardia or palpitations due to cardiac erythmism. The diuretic effect is slower to manifest itself, and we may have to wait twelve, twenty-four, or even forty-eight hours for it to show itself.

We must never lose sight of the dissociation of these two sets of effects, for this means that in certain well-defined clinical cases the action of digitalis remains purely cardiac, and the dose must not be increased in order to obtain a diuretic action, which is not to be expected in the absence of oedema awaiting absorption. This, too, explains the occurrence of poisoning by digitalis, an accident which can always be avoided with proper care, digitalis being by no means the "dangerous" drug that it is asserted to be. No doubt it is dangerous *in posse* when handled by the inexperienced, but it is uniformly innocuous in the hands of those who have learned to use this, the most powerful arm in the therapeutical arsenal, of those, in short, who know how to convert these alleged drawbacks into positive advantages.

The slowness of elimination, which means continuity of action, and the tendency to accumulation, which means reinforcement of the action, I turn to advantage in prescribing what I term the cardio-tonic dose—i.e., a tenth or a twentieth of a milligramme of crystallised digitaline. This is continued for several weeks in cases of heart disease at the stage of premonitory hyposystole. In this way, precisely on account of, and thanks to, the slowness of elimination and the tendency to accumulate, due to its insolubility, I can rely on its action, and am free from any apprehension of mischief. This slowness of elimination and prone-

ness to accumulate are two major qualities, because they ensure the organism remaining impregnated with the drug for long periods of time, which is not the case with drugs that are rapidly got rid of *via* the kidneys or other emunctories.

Moreover, accumulation can hardly take place with the minute doses just mentioned, since the drug is broken up in the organism from day to day. A reservation must be made in regard to patients confined to bed, because digitaline is more readily decomposed when patients are up and about than when they remain in the horizontal position. This is not to be explained on the assumption of orthostatic congestion of the kidney, the influence of which has been thoroughly investigated by Lenossier and Lemoine. These observers demonstrated that in the erect position the excretion of water, solids and urea is reduced, and we may even get albuminuria should the kidneys not be in good working order. In the case under consideration the orthostatic factor cannot be invoked, for the digitalis is destroyed in the tissues by movement and walking.

Since the slowness of elimination and the tendency of digitaline to accumulate are advantages rather than drawbacks, inasmuch as they ensure continuity and automatic reinforcement of its action, it behoves us to beware of the various pseudo-digitalines, the claims advanced on behalf of which are based precisely on their alleged solubility, rapid elimination and absence of accumulation. We must hold aloof from products which we are asked to regard as substitutes for the French crystallised digitaline; I mean more particularly Smiedeberg's and Kiliani's digitoxins, which, as Houdas remarks, "are not products possessed of a constant, well-defined composition," and which, under a very appropriate name, furnish evidence in abundance of a really dangerous degree of toxicity. Another digitoxin, possibly even more dangerous than the others, is that isolated by Cloetta, at first known as *digalene*, the inconstancy of action of which I have myself had occasion to observe. Yet Dr. J. B. Renaud, who advocated the use of this substance, continues to recommend it, although he ingenuously admits that it is a product which "does not appear to be well-defined and distinct from the other active principles obtained from digitalis." It is not easy to explain how an ill-defined drug which is soluble, rapidly eliminated, and does not tend to accumulate, can be even remotely compared with digitalis, which exerts a quasi-specific action. This digitoxin is anything you please except digitaline; indeed, it is not even digitalis, as we understand it, with its alleged defects which, on the contrary, are to be regarded as valuable qualities. The second conclusion, therefore, is that of all the active principles crystallised digitaline is the one to be preferred.

On the strength of more or less numerous experiments on animals, certain observers venture to assert that the action of given medicinal agents is "identical." This conclusion is certainly false, as far as digitalis is concerned. As I have pointed out on several occasions, there is great risk of error in arguing from experiments on animals to man, instead of from the healthy man to the sick man.

Even if it could be shown that digitalis acts on the vagi and not on the myocardium and vessels, or that it acts first on the peripheral heart, and then on the central organ; nay, even if we were to admit the three or four modes of physiological action described by Traube as appertaining to digitalis, there is one thing that can never be explained nor demonstrated by such experiments—viz., the difference between the action of digitalis on a healthy man and on one who is suffering from

heart disease, and between its action on the latter at two different stages of his cardiopathy. For instance, at the stage of eusystole or confirmed asystole with oedema, in the first case we only obtain a feeble cardiac action and no diuretic action at all, whereas in the second we get very marked cardio-vascular and diuretic action. This fact justifies the conclusion that the physiological action of the drug, especially of digitalis, must be studied not only in animals, but also and more particularly in the sick; indeed, as I have already pointed out, clinical medicine is essentially the study of the physiology of the disease, of the patient and of the drug.

Doubtless we must first of all ascertain the physiological action of the drug in animals, but we must bear in mind that experiments are only artificial observations, that in experimental deduction the experimenter cannot be separated from the observation, as Claude Bernard used to say, and that the physiological study of drugs, begun on animals, ought always to be continued at the bedside by clinical observation, which amounts to spontaneous experiment.

I would add that although it may be possible to determine experimental valvular and myocardiac lesions, or, for the matter of that, renal lesions, no one has yet succeeded in provoking a cardiac lesion with its asystolic syndrome. It follows that there is a physiology which must be studied in the sick, and this proves once again that clinical observation and physiology must co-operate and mutually assist each other.

I am never tired of repeating Pecholier's words, that "every drug comprises several drugs"—i.e., that in clinical physiology the same drug exerts a different action when given in different doses. Now there are three ways in which we may prescribe crystallised digitaline in response to three special indications in disease, especially in heart disease:—

1. *Massive Dose*.—This is the anti-asystolic and diuretic dose. In presence of asystole we may order as much as 1 milligramme of crystallised digitaline once or twice a day—a very good plan and the one adopted by Potain. In thirty-six or forty-eight hours there is profuse diuresis with strengthening of cardiac-contraction, absorption of oedema, diminution or disappearance of visceral congestion, and enhanced elimination of the chlorides. Should the effect fall short of our requirements, we may, indeed, ought to, repeat the drug a week or two later in the same or a rather smaller dose— $\frac{1}{2}$  to  $\frac{3}{4}$  milligramme. When the diuretic action has exhausted itself, as shown by the disappearance of the oedema, should cardiac contraction still be weak, we ought to prescribe, in ten days or a fortnight, for one, two or even three weeks, crystallised digitaline in very small doses (the cardio-tonic dose), as will be shown later.

2. *Small Dose*.—This is the sedative dose indicated for the relief of palpitation, cardiac erythmism and dyspnoea associated with mitral stenosis, even during the period of perfect compensation. We may give a  $\frac{1}{4}$  milligramme granule for three or four days, to be repeated every three or four weeks. This plan is very useful in the dyspnoea of mitral stenosis by determining an actual prolongation of the diastolic period—i.e., the period during which the heart is being filled. And this in spite of the fact that Potain asserted digitalis to be absolutely contra-indicated in mitral stenosis, because in this disease, he says, "the heart is tuned for a small amount of work, and digitalis increases this work." This is a grave error, for if the drug really had for effect to increase the work of the heart, its use would never be indicated in any form of heart disease in which, on the contrary, it is our duty,

as in lesions of any organ, to lighten, relieve and facilitate its work, which is exactly what digitalis does. Moreover, clinical experience and observation are there to prove the excellent effects of digitaline in mitral stenosis, which is possibly the only form of fully compensated heart disease in which the drug is really indicated.

3. *Very Small Dose.*—This is the maintenance or cardio-tonic dose, the one that exerts a purely cardiac, non-diuretic action which can be persevered with for weeks and months, allowing an interval of repose of a week or two every fifteen or twenty days. It has for object and result, in daily doses of 1-10th milligramme, to reinforce the heart without the least risk of the supervention of even the slightest symptoms of intoxication, since, on account of its slowness of elimination, a certain quantity of the drug remains in the organism and exerts its tonic effect on the myocardium.

In urgent cases crystallised digitaline may be injected subcutaneously without giving rise to any local irritation. We are indebted to Rosenthal, Martignac and Lasnier for this injectable digitaline, which is an oily solution obtained by the aid of a rather high temperature, containing a  $\frac{1}{4}$  milligramme in each cubic centimetre, as suggested by me. The injection of digitalised oil, which causes very little pain and is promptly absorbed, is of advantage, in that the drug acts more rapidly, and the risk of setting up gastric intolerance is obviated without exposing the patient, as was at one time believed, to any greater liability to toxic symptoms.

If I have succeeded in making myself understood, no hesitation or apprehension will be experienced in administering digitaline in accordance with the definite rules which I have briefly laid down. In the doses recommended every therapeutic indication can be fulfilled, and we cannot too often repeat to ourselves the words of an Italian physician of the sixteenth century (Cappiovaccio, of Cremona):—"Learn how to prescribe remedies, and you will complain less of their inefficacy and their dangers."

I will conclude with the general precept that Nativelle's crystallised digitaline is almost invariably to be preferred to the various preparations of digitalis. Just as there is no substitute for digitalis, so there is none for crystallised digitaline. Schmiedeberg's and Cloetta's digitoxins are untrustworthy and even dangerous, and under no circumstances can they take the place of crystallised digitaline.

This is all we need to know, and this my rather extensive experience enables me to affirm. I trust I have satisfied my readers that the dangers of digitaline and the drawbacks of digitalis are non-existent, and I hope I have inspired them with that confidence in themselves when making use of this invaluable agent, without which there can be no such thing as therapeutics.

**NOTE.**—*A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by Dr. T. D. Lister, Physician to Out-Patients, Royal Waterloo Hospital for Children, and Physician to the Mount Vernon Hospital for Consumption and Diseases of the Chest. Subject: "Infantile Scurvy."*

FORTY-THREE recent cases of scarlet fever attributable to a certain milk supply have been reported to the Westminster City Council.

IN a report on the work of the Central Midwives Board for the past twelve months, it is stated that the midwives' roll has increased by 1,647 names, the total on March 31st, 1909, standing at 27,281.

## ORIGINAL PAPERS.

### MYOTONIA ASSOCIATED WITH MUSCULAR ATROPHY AND MYASTHENIA.

By PROFESSOR CHVOSTEK,

Vienna.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

IN a lecture to the members of the Gesellschaft für Innere Medizin, Chvostek endeavoured to show the close relationship that existed between myotonia, muscular atrophy, and myasthenia, and affirmed that the cause was hæmopoietic or glandular in its origin. Myotonia congenita carries us back to the days of Thomsen, who first described the disease in 1876 as hereditary and congenital, although it was previously noticed by Charles Bell in 1832, and later by Leyden in his "Klinik der Rückenmarkskrankheiten" for 1874. Seebigmüller, Strümpell, Bernhardt, Eulenburg, and Erb confirmed the Thomsen disease as a typical malady, and classified it, according to their knowledge of the disease at the time, myotonia congenita. Later it was discovered by Süsskand and others that no clear hereditary proof could be shown in many cases, which led to a new term, myotonia acquisita. These cases were observed to commence between the ages of twelve and sixteen years, beginning with psychical and somatic disturbance. Although Thomsen had proved the heredity in his own cases for five generations, Talma and Jolly now demonstrated that the disease appeared in isolated families at adolescence.

The symptoms were described as tonic contractions and stiffness in the voluntary muscles when any effort was attempted after a state of rest, but after the function was once restored all the functions of the body seemed normal. The extremities were the usual site of the phenomena. Rising from a chair, the patient found himself locked, and had to wait on a process of thawing before he could move, but once relaxed, he had no more difficulty that day till he rested again. It does not seem to interfere with the endurance, as these patients can undergo long, tedious, hard labour without feeling tired. If the arms, fingers or legs be firmly flexed the same stiffness may be produced. Writing and piano-playing induce the rigidity, or bending the arm with a glass of water will lock the hand to the glass in the flexed position till he relieves it with the other hand.

The muscles are usually well nourished, having no appearance of dystrophia, but any irritation of the nervous system or cutaneous surface may produce this locking in any muscular group.

Electrical examination is of little value when the current is light, but the myotonic action is produced when a very strong current is used by long and slow waves in the muscular bundle, lasting from a quarter to half a minute, and in many cases to three minutes. This description is more peculiar to an intense faradic current. The galvanic current has not the same tardy effect, but the anode closure is abnormally lighter than the cathode closure, while the latent interval is greatly increased. Erb discovered rhythmical waves in muscular groups passing between the cathode and anode when 20 milliamperes were used.

The myotonia, though easily recognised in simple cases, is often associated with epilepsy, hysteria, hemiplegia, etc., but the absence of atrophy is usually acknowledged as diagnostic, and when this is present, as in the case before you, associated with myasthenia, the confusion is in-

creased. If you examine this case carefully you will find the fatty substance has almost disappeared, although the patient has been well nourished, but, owing to the irregular movement in the alimentary canal, assimilation has been interfered with. Both testes are atrophic and the small bones of the larynx are greatly enlarged. The Röntgen photos of the cranium show a greatly increased cavity in the pterygoid bone, and therefore contraction of the sella turcica. The struma are moderately developed, but atrophy is present in almost all the muscles of the body, and particularly prominent in those of the temporal and masseter regions, where luxation of the lower jaw frequently takes place when the patient opens the mouth. There is also atrophy of the tongue, paresis of the fauces, and feebleness in the muscles of the neck. The atrophy is pronounced in the cucullaris and sternocleidomastoid muscles, with weakness of the rhomboid. The deltoids are also atrophied, but the right more than the left, the contractions of the latter being longer, and thus presenting a pseudohypertrophy. The atrophy of the muscles of the upper and lower extremities are more pronounced in the gluteal than in the hand, thus producing a weakness in fixing the pelvis or extending the legs; the left being more marked than the right. No fibrillary movements are present in the deeply-affected muscles, but small fasciculæ may be observed here and there. The tendon reflex as well as the periosteal, is lost in both upper and lower extremities. When attempting to grasp any object the "intentions" of cramp are pronounced, and the movement of the legs is plastic, with stiffening of the eyelids after closure. The myotonic phenomena disappear after repeated movements, which may be easily demonstrated in the tongue, quadrangularis menti, biceps, thenar and anti-thenar muscles, and in a lesser degree in the deltoids and quadriceps cruris.

The electric examination reveals the myotonic reaction distinctly in the right biceps, quadrangularis menti, and the muscles of the thumb, though absent in the triceps and extensors of the forearm, the right quadriceps, and muscles of the calf of the left leg.

These results reveal extensive changes in the muscles resembling dystrophia, but there is no proof of spinal muscular atrophy, syringomyelia or tabes being present, and, from the same reasoning, neurotic changes are absent. Although the sensibility is disturbed, it is more functional than real, owing to the changes in the skin, the loss of fat and other alterations in the nerve system. By the same reasoning the absence of myotonia may be demonstrated. The myasthenic symptom, in rapidly becoming tired and exhausted, may be due to the loss of muscular substance, and is not easily explained.

From these facts and phenomena we learn that myotonia is not a simple primary muscular disease, although there are congenital anomalies at a very early period of its history, but many of the manifestations gradually develop during the course of a long disease. We must, therefore, look further for a deeper-lying disturbance than muscles, teeth and hypertrophy, which have been frequently the source of careful examination, and found untenable as the real source of the disease. From the number of typical cases that present themselves, and the different courses that the disease take, Pelz has come to the conclusion that myotonia and muscular atrophy are one and the same thing; and from the symptoms associated with them, such as the loss of fat, distribution of the blood-vessels and psychical cases, epilepsy, altered blood-vessels and metabolism, are all in favour of a central disease. No

doubt the myotonia has much to commend itself as a central disease from the frequency of associated wasting of the muscles, and differing from general changes present. From these symptoms Schieferdecker has evolved another theory of sarcoplasma, in consequence of fibrillary disease, hypertrophy of the muscular fibres and changes in the nerve ganglia, which he looks upon as secondary; but this theory is as difficult to understand as many of the others, as a simple stroke, according to Kornfeld, will induce the myotonia. Hoffmann is inclined to believe in this theory and that the myotonia is lying latent in the muscle, and only requires this stroke to produce the morbid manifestation. The congenital theory has long been maintained, and, from its resistance to all forms of treatment, has been accepted as the most plausible, though some mysterious change is undoubtedly present in the muscles, but when the whole symptoms are viewed consecutively, we must confess that the disease is more remote than muscles and plasma, and appears to belong to the blood glands or blood formation. In support of this view, the various phenomena, without any clear explanation, force us to believe that the disease lies deep in the hæmopoietic system. Myotonia is not unusual after extirpation of the thyroid, and in the case before us we have atrophy of the testes, an early appearance of bone formation in the larynx and thorax, and general wasting, to support the belief in the blood glands being the remote source of the disease. Again, the myotonic reaction in children and the hibernation of animals favour the same argument; hence the close relationship between tetany and myotonia which is acknowledged by many. Although we have no direct proof of tetany and myotonia being manifestations of the same morbid change, we have strong circumstantial evidence that the epithelial bodies of the thyroid with the "chromaffinity system" are the real proximate cause of the disease, modified, of course, by the influence of the sympathetic system on striped muscular tissue. This may explain the impotence of treatment and the hopeless results hitherto obtained.

## THE PREVENTION AND TREATMENT OF MALARIA IN TROPICAL COUNTRIES. (a)

BY MAJOR RONALD ROSS, C.B., D.Sc.Dub.,  
F.R.C.S.Eng.,

Professor of Tropical Medicine, University of Liverpool.

EVERY sanitary officer who desires to reduce malaria in the district committed to his care is sure to be confronted from the outset by a large number of difficulties with which, perhaps, he does not know exactly how to deal. Let us ask ourselves what we should do if we were put in the place of this sanitary officer—whether he be the sanitary administrator of a country, a colony, or a state, or the health officer of a city, town, a station, or a rural district. Malaria is due to a miasma given off by the marsh; but the miasma is not a gas or vapour—it is a living insect. The germs of malaria do not live in the marsh; it is the carriers of the germs which live there. The Anophelines themselves are the malarial miasma. The careful thinker may, however, still ask whether science may not be mistaken in this matter as she is said to have been mistaken in others. Only those who have studied the subject can reply. We have to deal here with a large body of observations made by many workers. Every phase of the parasites, both in the vertebrate and in the insect hosts, has been minutely figured and described over and over again, and numerous experimental infections have been achieved.

(a) Abstract of Paper read before the *Materia Medica* Section, Indian Medical Congress, Bombay, Feb. 22nd, 1909.

Wonderful though it is, the life-history of the parasites of malaria is simply the same in general as that of numbers of other well-known parasites. Lastly, the disease has been abruptly cut short by measures based on these results. This accumulated mass of evidence is based, not on mere empirical opinion—to which most of the errors falsely attributed to science have been due—but on a secure microscopical and experimental foundation.

The next question is this one: Will the campaign repay the money and trouble likely to be spent upon it? There are two columns to this account. The cost of the campaign is often discussed, but not so frequently the cost of the disease. Take, for example, the case of a military station. Every man on the sick list means a loss to Government of so many days' pay, and every man invalided to Europe or to the Hills means an addition to the cost of transport. Every death means the loss of a trained soldier—that is, of all the money spent on his training—and an unhealthy station spells a large hospital and an expensive medical staff. But I fancy that these expenses are small compared to the cost of the disease during active service. Malaria is essentially a relapsing malady. A man once infected and not thoroughly cured is likely to suffer from relapses when exposed to fatigue (as proved in several ways). What happens, then, when a regiment "soaked with malaria" goes down out of barracks on service? In such a case a large percentage of the strength is probably infected before starting—with the result that man after man "goes down" with fever when subjected to the hardships of war, and many have to be invalided. Add to this the number of men infected *en route*, and we shall understand how great the cost of military expeditions in the Tropics must be enhanced by the disease—not to mention the loss in military strength. Similarly, in civil towns and stations, we must reckon up the cost of sickness and invaliding among the employees of the State, from the highest officials to the staff of sweepers and the gangs of workmen in the streets. In plantations the cost is often quite crippling to the planter, since from 5 to 20 per cent. of the indentured coolies may sometimes be laid up daily during the busiest seasons. What the cost may be to the general civil population cannot be exactly estimated, but it must be gigantic.

The measurement of malaria in a district will cost Government little or nothing beyond, perhaps, the ordinary travelling expenses, and will involve but small additions to the work of officials. The measurement being completed, the sanitary department is now in a position to commence the campaign, if such is decided upon, without further investigation. I say so advisedly for reasons which will appear presently.

Fortunately, we have many weapons against malaria, and they have been so frequently described and discussed that it is unnecessary to labour the point here. They may be classified as follows: (a) parasite reduction by the use of quinine; (b) mosquito reduction by drainage and other means; (c) subsidiary measures such as wire gauze segregation, public instructions, etc.; but after ten years' experience we may, I think, venture to lay down without further discussion the following rules regarding the special applicability of each:—

(1) All anti-malaria measures are good and useful, and each should be employed in its proper place.

(2) For cities, towns, large stations and other dense populations, mosquito reduction will probably be the most appropriate measure, because in such, (a) the cost of drainage benefits a large number of people and can be better borne by them; (b) its cost will probably be less than the cost of effective quinine distribution among so many; (c) the measure will tend to remove other diseases and annoyances besides malaria, and (d) it can be carried out by the authorities on their own initiative without making demands on the populace to take drugs, use mosquito nets, and so on.

(3) For scattered populations, small villages, and rural areas we must generally fall back upon quinine, because the cost of drainage (which is as great or greater in the country as in the city) is likely to accrue from it.

(4) In the presence of severe malaria, both mosquito reduction and parasite reduction should be employed

together, and the subsidiary measures are to be used in special cases.

In considering this list, the sanitary officer will always ask: Where is he to begin? What must he do first? The answer may be put in the form of the fifth rule:—

(5) Begin with those measures which can be immediately adopted—that is to say, as a general rule, with the cheapest ones.

We know that native children are the principal homes of the parasites of malaria. Now most tropical countries are advanced enough to possess numerous schools—either supported entirely by Government or assisted by "grants-in-aid." These can be utilised at once, without any delay, for a double purpose—(1) for the treatment of sick children, and (2) for the continued measurement of malaria. I have recommended the following procedure for Mauritius:—

(1) Every schoolmaster should keep a "Spleen Register" of the children in his care. (2) Every school should be visited on any convenient date once a quarter, either by the sanitary officers, or by trustworthy medical assistants. (3) The inspector should examine as many of the children as possible at each inspection, and should note in the register, opposite the name of each, whether he is suffering from enlarged spleen or fever, and what dosage of quinine should be given to him during the next three months. (4) The master should endeavour to carry out his directions to the best of his ability by giving the drug as ordered. If you wish to influence the disease seriously by quinine, you must deliver it at the houses of the poor, either for nothing or for a very small payment. This is not really expensive, and we should proceed as follows:—Select the most malarious area at hand, and appoint a trustworthy dispenser for the work. Give him a large wallet full of assorted quinine pills and direct him to deliver them from house to house to all who wish to take them. Moreover, enough of the pills to suffice for daily dose (say, 5 gr. for the adult) during a fortnight should be given. In this way the dispenser can visit any fifty houses a day, and as he need visit each house only once a fortnight, he can generally deal with 500 or 600 houses. A large and severe epidemic at Phoenix, in Mauritius, was absolutely cut short in two months last year by this procedure, combined with drainage. For the whole of Mauritius, with its population of 375,000, and its spleen rate of 34 per cent., I advised five such dispensers, costing only Rs.6,000 per annum, exclusive of the quinine.

On consideration, I think that this organisation (as regards schools and dispensers) practically sums up what can be usefully done in the way of public quinine prophylaxis in the Tropics. My estimate for the cost, preparation and distribution of quinine in Mauritius was Rs.33,600 per annum, but that island possesses many planters' dispensaries. A wider distribution, as at Panama, will, of course, cost much more, but not every district has such funds at its disposal.

With swarms of carriers in every direction it is as difficult to put down the disease as it would be to put out a fire so long as someone else continues to relight it.

Complete extermination of the insects is never demanded, and a diminution is sufficient. We can have no misgivings as to this conclusion, because every year Nature makes the experiment before our eyes in the simultaneous decline of malaria and Anophelines together at the end of the rainy season. The second main theorem is that by the laws of chance, however far an insect may occasionally wander from its breeding place, the majority of insects bred there will tend to remain near it. A puddle near at hand may cause as much mischief as a large marsh a mile away. Other points of importance are (1) that, as the same organisation suffices to deal both with the Anophelines and the Culicines, we may as well include the latter in the campaign; and (2) that, following the general principle recently suggested, it is always advisable to begin by attacking the smaller breeding places—in other words, "minor works before major works." Before committing the State to the expense of draining large marshes, see what can be done by removing the small collections of water near houses.

The organisation now described is that which has been recommended for Mauritius: (1) The head of the Sanitary Department can always organise the preliminaries of the campaign, such as I have outlined above, by himself; but will need a special assistant when the work develops. For a single town or station, a trustworthy sanitary inspector, placed under the local sanitary authority, ought to suffice; but a colony or province will require a well-qualified medical man, zoologist, or, perhaps, engineer. His duties will be to direct and supervise all the operations, under the head of the Sanitary Department; to collect the statistics, and to prepare the annual malaria report (which will be suggested presently). I conclude that this official is absolutely necessary if continued success is desired. Without him, efforts are likely to be only spasmodic; the campaign may be abandoned after a time; money will be wasted, and the whole business will be discredited. In fact, this is just what has happened in several cases—an energetic medical officer has commenced a campaign, which has been dropped on his leaving the station.

(2) Under the special "malaria assistant or director," it is necessary to appoint a certain number of intelligent subordinates, who may be called "Malaria Inspectors" (an excellent name used in Mauritius, and suggested by Colonel Peterkin, R.A.M.C., is *moustiquier*). Each man, after a sufficient training in the habits of mosquitoes and allied matters, is placed in charge of a given area of, let us say, ten square miles, more or less. His principal duty is to seek out and know the breeding places of all kinds of mosquitoes within that area; but he must also keep an eye on the working gangs, become well acquainted with the houses and villages, guide the quinine dispensers, and, in general, be the lieutenant of the "malaria director" within the area allotted to him.

The actual labour should be performed, workmen organised in small "malaria gangs" of by about three men each. One of the men should be the head man of the gang, and receive a little higher salary; he should direct the others, but must also do manual work himself. The men should be of the gardener class, accustomed to labour on the soil. Each gang is allotted a given area, within which they must constantly carry on all the necessary "minor work"; that is, clearing water channels and dams, rough-training streams, dumping in holes and pits, and training small marshes, waste waters, and so on. In the dry weather their attention is turned largely to the tins, bottles, and other rubbish, the examination of cisterns and tanks, filling of holes in trees, etc., in fact, all the well-known anti-mosquito work. As I have frequently urged, these gangs make an invaluable addition to the ordinary staff of the Sanitary Department.

The procedure and organisation which I have attempted to sketch out is mainly that recommended for Mauritius, but this does not mean that it is by any means an organisation suitable only for that island. In fact, all the details have simply been selected and developed by the chief medical staff of Mauritius, and by Major Fowler and myself from similar details of the campaigns conducted in Sierra Leone, Panama, Ismailia, Federated Malay States, Ceylon and elsewhere. Any further hints on the various points raised, or notes of actual experience in the field, would be of assistance in further developing this vital matter of organisation.

## THE POISONS AND PHARMACY ACT, 1908, IN RELATION TO PUBLIC HEALTH AND SAFETY. (a)

By H. WIPPELL GADD, F.I.C.,

Of the Middle Temple, Barrister-at-Law.

THE safety of the public has been the keynote of all Acts of the Legislature of this country restricting or regulating the sale of poisons. "Whereas the unrestricted sale of arsenic facilitates the commission of crime" runs the preamble to the Arsenic Act, 1851, the earliest statute dealing with such matters.

(a) Abstract of Paper read before the Medico-Legal Society of London, June 22nd, 1909.

"Whereas it is expedient for the safety of the public" begins the Pharmacy Act, 1852, and in the self-same words opens the preamble to the Act of 1868.

It is not merely, however, with the distribution of poisons, as such, that pharmacy Acts deal; they regulate also (indirectly and imperfectly, it is true, but still usefully) the dispensing and retailing of many of the medicines required for or desired by His Majesty's subjects.

They have created an educated class of workers, possessing a sense of responsibility engendered by their training, and have thus brought about a great improvement in the purity of drugs and the accuracy of dispensing.

Such legislation has, therefore, a profound influence upon the public health, and cannot fail to be of interest, not only to jurists and physicians, but also to statesmen and philanthropists; whilst it should particularly appeal to medical officers of health, coroners, and all who have official charge of sanitary matters, or have to inquire into the causes of disease, accident and death.

It is not my purpose to-night to say much about Act 31 and 32 Vic., Chapter 121, generally known as the Pharmacy Act, 1868, by which these matters have, up to April 1st of the present year of grace, been controlled, except in so far as it is necessary to refer to it to explain the provisions of the new statute, the Poisons and Pharmacy Act, 1908, 8 Edward VII., Chapter 55, by which it has been modified in some important respects.

There is no preamble to this latter Act, no expression of concern for the safety of the public, no statement that the ready accessibility of poisons leads to crime. The omission is, perhaps, insignificant, and in accordance with modern methods of draftsmanship, but it is certainly discreet, in view of some of the provisions of the Act, and the genesis of the agitation which caused them to be enacted.

Coming, therefore, at once to Section 1, Sub-section 1, we read:—"Schedule A to the Pharmacy Act, 1868, which specified the articles to be deemed poisons within the meaning of that Act, is hereby repealed, and the schedule to this Act shall be substituted therefor."

I may remind you that the sale by retail in Great Britain of articles in Schedule A of the Pharmacy Act, 1868, is restricted to persons who are registered chemists or registered medical practitioners, and that the scheduled poisons are divided into two parts.

The requirements on retail sales of poisons, both in Part I. and in Part II. of the Schedule are briefly: As to poisons in both parts, the vessel, wrapper, or cover containing them must bear a label distinctly stating—

- (a) The name of the article.
- (b) The word "Poison."
- (c) The name and address of the seller—that is, the proprietor of the business.

Further, no poison in Part I. may be sold to any person unknown to the seller, unless he or she is introduced by some person known to the seller, and on every sale of any Part I. poison, the seller must, before delivery, make, or cause to be made, in a book to be kept for that purpose, commonly called "The Poisons Book," an entry of—

- (1) The date of sale.
- (2) The name and address of the purchaser.
- (3) The name and quantity of the article sold.
- (4) The purpose for which it is stated by the purchaser to be required.

A number of changes are introduced in the present Act, and may be seen on reference to the Schedule.

Section 1, Sub-section 2, reads:—"The Schedule to this Act may be amended by adding thereto or removing therefrom, any article or by transferring any article from one part of the schedule to the other in the manner provided by Section 2 of the Pharmacy Act, 1868, for adding to the list of articles deemed to be poisons within the meaning of that Act."

The procedure referred to is the passing of a resolution by the Council of the Pharmaceutical Society declaring that any article in such resolution named ought to be deemed a poison within the meaning of

the Act, with the subsequent approval of the Privy Council and advertisement in the *London Gazette*.

It has not always been easy to obtain the addition of substances to the list of poisons, the Council of the Pharmaceutical Society having submitted the names of many drugs to the Privy Council, from time to time, without success.

#### REGULATION OF SALE OF CERTAIN POISONOUS SUBSTANCES FOR AGRICULTURAL AND HORTICULTURAL PURPOSES.

Sec. 2.—(1) "So much of the Pharmacy Act, 1868, as makes it an offence for any person to sell or keep open shop for the sale of poisons, unless he is a duly registered pharmaceutical chemist, or chemist and druggist, and conforms to the regulations made under Section 1 of that Act, shall not apply in the case of poisonous substances to be used exclusively in agriculture or horticulture for the destruction of insects, fungi, or bacteria, or as sheep dips or weed killers which are poisonous by reason of their containing arsenic, tobacco, or the alkaloids of tobacco, if the person so selling or keeping open shop is duly licensed for the purpose under this section by a local authority, and conforms to any regulations as to the keeping, transporting and selling of poisons made under this section, but nothing in this section shall exempt any person so licensed from the requirements of any other provision of the Pharmacy Act, 1868, or of the Arsenic Act, 1851, relating to poisons: Provided that His Majesty may by Order in Council amend this provision by adding thereto or removing therefrom any poisonous substance, and, upon any such Order being made, this provision shall have effect as if the added poisonous substances were included therein, and the removed poisonous substances were excluded therefrom.

This clause makes a notable exception to the principle laid down in the Pharmacy Act, 1868, that poisons shall only be sold by persons who have been specially trained.

For the first time since there ceased to be Free Trade in toxic articles can poisons in the legal sense—that is to say, substances included in the Schedule of the Pharmacy Act, be sold by persons other than registered chemists, and druggists, and medical practitioners, and it is to this innovation that I wish to particularly direct your attention to-night.

What was the genesis of the concession? It was alleged, doubtless with truth, that in the Highlands and Islands of Scotland, where sheep farming is the principal industry, farmers are sometimes fifty miles and more distant from the nearest registered chemist and druggist, and therefore are inconvenienced in the conduct of their industry.

It was further alleged that the sale of poisonous preparations for use in horticulture was not sufficiently fostered by the chemists and druggists, and that in Kent inconvenience had been caused to growers and nurserymen.

The wail of the market gardeners over their not very serious grievances was reinforced by more clamorous cries from manufacturers of attractively produced poisonous proprietary preparations for horticultural purposes, compounds of arsenic and honey, and the like, the sale of which, they alleged, doubtless with much truth, chemists and druggists did not promote as zealously as they might have done.

The fact is, that a chemist and druggist is trained to regard the sale of poisons with disfavour. He, alone amongst traders, with the possible exception of the better-class publican, often persuades his customer to buy less than he wishes of dangerous substances, and, indeed, constantly declines to sell at all things which might bring him an immediate pecuniary profit, but the indiscriminate distribution of which would be detrimental to the common weal.

Moreover, the policy of the Pharmaceutical Society, which is the prosecuting authority for breaches of the Pharmacy Act, has ever been to refrain from interfering with legitimate transactions which might be technically illegal. It has allowed manufacturers to supply sheep dips direct to farmers without let or hindrance, and has taken a liberal view of the meaning of wholesale dealing and the law of agency.

However, a Departmental Committee appointed to

consider these matters reported, in November, 1902, *inter alia*, that, in their opinion, preparations for use in connection with agriculture, horticulture, or sanitation, might be placed in a third part of the schedule, to be sold only by licensed vendors and subject to regulations to be made by the Privy Council; and, after a somewhat lengthy interval, these suggestions have crystallised into a concrete form in Section 2 of the Act of last year.

It will be noticed that the licence is a personal matter, and it is doubtful if it can, therefore, be granted to a partnership or body corporate, as such, although doubtless it may be granted to the individual partners or to an officer or servant of the body corporate.

Further, it will be noticed that nothing in this section is to exempt any person licensed thereunder from the requirements of any other provisions of the Pharmacy Act, 1868, or of the Arsenic Act, 1851, and it is submitted therefore that every sale must be personally conducted, or at least superintended by the licensee, in accordance with the judgment pronounced by Hawkins J. in "*The Pharmaceutical Society v. Wheeldon*," 1890, 24 Q.B. 682, wherein he said:—"The whole object of the Act would be frittered away, and the Act itself become a dead letter, were we to declare by our judgment that an unqualified assistant can lawfully and with impunity sell any of the poisons to which the Act applies, unless upon every occasion of such sale he acts under the personal supervision of a qualified employer, or a qualified assistant to such employer. By such personal supervision we mean, not mere presence in the shop or room where the sale takes place, but actual personal supervision."

It is submitted that a qualified person for the sale of these poisonous substances now means either a registered chemist and druggist, or an individual licensed under this section.

One more point may be noted in passing, that, although at present licences can only be granted for the sale of preparations of arsenic and tobacco, and the alkaloids of tobacco, it is provided that other poisonous substances may be added to the list, not by the circuitous process provided by Section 2 of the 1868 Act, which I have already outlined, but by Order in Council.

Regulations as to licences to be granted under this section were made by Order in Council on April and last. Regulation 2 should be read in conjunction with Sub-section 2 of Section 2 of the Act, which provided that, before granting any licence, the local authority shall take into consideration whether, in the neighbourhood where the applicant for licence carries on or intends to carry on business, the reasonable requirements of the public with respect to the purchase of such poisonous substances are satisfied. Obviously, therefore, the regulation is not a mandate that licences shall be granted to nurserymen, florists, and seedsmen, but a recommendation that, should it be found necessary to grant licences to unqualified persons at all, preference should be given to such traders.

Regulation 5 practically reiterates Sub-section 2 of Section 2 of the Act, but gives the status of objectors to the police and existing vendors—that is, chemists and druggists—alone.

Objections by existing vendors are naturally looked on with suspicion, as being like those of Demetrius and his fellow-craftsmen at Ephesus, whilst the police in most cases appear content if they know nothing against the would-be licensees.

Regulation 13 is consoling to those who do not wish to have their bacon, as once was their beer, arsenically flavoured.

I have come now, at last, to the *raison d'être* of what is, I fear, a somewhat arid essay.

How is Section 2 of the Act being interpreted by local authorities?

Up to the end of May some 600 applications had been received for licences, of which more than half were from nurserymen and seedsmen, and by far the greater proportion were evidently required for horticultural purposes, rather than for agricultural.

These have been dealt with in a manner varying with the taste and fancy of the respective Councils, to whom applications have been addressed. In some

cases they have been referred to committees with power to act, and in others for report, the reports in many instances having been promptly ignored by the Councils.

A curious feature has been that a number of applications have been received in large towns, where one would think there was no doubt that the reasonable requirements of the public were already fully met. Thus, applications have been received in five towns having a population of half a million and over; in 14 towns with between 100,000 and 500,000; 15 towns with between 50,000 and 100,000; 27 towns with between 20,000 and 50,000; 23 towns with between 10,000 and 20,000; and between 50 and 60 towns with a population varying from 1,000 to 10,000.

In all, nearly a quarter of the applications have been granted, and many are yet pending.

The reasons for granting them have been varied and original.

Thus, on the occasion of the County Council of Carmarthenshire granting a licence, a member of the Council supported the application because he thought it would help to pay expenses, whilst the chairman, a medical practitioner, considered that the licences would help to break down a monopoly.

The Public Control Committee of the London County Council, in reporting regarding the poison licences, stated that, "so far as London is concerned, the wholesale dealers or pharmaceutical chemists, etc., will be able to supply the demand for poisons for use in agriculture, but the Committee thinks certain licences should be issued by the Council according to the requirements of the various neighbourhoods, since it is contended that, as florists and seedsmen developed the trade in poisonous substances for horticulture, they are therefore entitled to any profit arising from that trade. The Committee did not anticipate any danger to the public from the granting of licences, as it is the practice for seedsmen to require written orders for substances containing arsenic, which are then executed by the manufacturer, the seedsmen acting only as an agent."

This is a curious recognition of a vested interest created by illicit trading, but it was endorsed by a Committee appointed at Walsall which reported that all persons who have hitherto been in the habit of selling agricultural and horticultural poisons should be licensed for three months.

At Burton-on-Trent, a gleam of light would seem to have illuminated the local authority, as they entrusted the Medical Officer of Health with the duty of carrying out the provisions of the Act. However, when five chemists stated that they were prepared to supply all poisonous agricultural and horticultural preparations, and petitioned that no licences should be granted, the Committee answered that the regulations provided that preference should be given to nurserymen, possibly thinking that the chemists wanted licences.

Another authority actually offered a licence to a chemist who wrote petitioning against the granting of such to unqualified vendors.

The Invernessshire Council decided that licences be granted to all respectable general merchants who applied for them, and in a large number of cases licences have been given in populous towns where chemists abound.

Doubtless there are various local conditions which are known only to those resident in the respective districts, so that a measure of local option may be desirable and wise. Moreover, the actual number of chemists in a locality is not necessarily a criterion of the number who are able and willing to supply these special preparations.

In some cases the nature of the pharmacies does not permit their undertaking a heavy trade, and in others the difficulties of delivery would serve as a deterrent.

Again, when two licences were granted at Fort William, in Wigtownshire, no one could object, considering that the nearest chemist is ten miles away; but why should licences be granted in Manchester, where there are said to be 250 chemists, or in Sheffield, with over 100.

My object in calling attention to these matters is that those who have local influence in different parts of the country should exercise the same in seeing that

the intentions of the Act are carried out, or at least understood.

Medical officers of health and coroners should be specially interested in the subject, provided always that the emoluments of the latter do not depend upon the number of inquests which they conduct.

Clause 3 of the Act remedies certain anomalies in the conduct of the business of a chemist and druggist, and emphasises and enforces the personal qualification of the actual conductors of such business. Thus the first sub-section runs:—

"Any person who, being a duly registered pharmaceutical chemist, or chemist and druggist, carries on the business of pharmaceutical chemist, or chemist and druggist, shall, unless in every premises where the business is carried on the business is *bonâ fide* conducted by himself or some other duly registered pharmaceutical chemist or chemist and druggist, as the case may be, and unless the name and certificate of qualification of the person by whom the business is so conducted in any premises is conspicuously exhibited in the premises, be guilty of an offence under Section 15 of the Pharmacy Act, 1868."

This prevents qualified chemists owning and conducting more than one shop, unless in each one where they are not *bonâ fide* in charge themselves they have a qualified manager.

Sub-section 2 reads:—

"The provisions of Section 16 of the Pharmacy Act, 1868, which enable the executor, administrator, or trustee of the estate of a deceased pharmaceutical chemist or chemist and druggist to continue his business so long as such business is *bonâ fide* conducted by a duly qualified assistant, shall be construed as enabling such executor, administrator, or trustee to carry on the business if and so long only as in every premises where the business is carried on, the business is *bonâ fide* conducted by a duly registered pharmaceutical chemist or chemist and druggist, as the case may be, and the name and certificate of qualification of the person by whom the business is so conducted in any premises is conspicuously exhibited in the premises."

This provides more effectually than was done by the 1868 Act for the *bonâ fide* conduct by a qualified person of the business of a deceased registered chemist.

It will be noticed that in both cases a certificate of qualification has to be exhibited.

Sub-section 3 runs as follows:—

"A registered chemist or druggist may, notwithstanding anything in Section 15 of the Pharmacy Act, 1868, take, use, or exhibit the name or title of pharmacist."

The reason for this provision is that the title "Chemist" which has always been somewhat inappropriate as a description of a dispenser of medicine, had been usurped by corporate bodies, and it was desirable to reserve a title strictly to individuals which should be of the nature of a personal title, akin to that of solicitor or dentist.

The word "pharmacist," which had been previously reserved for pharmaceutical chemists, was thought to be the most generally suitable.

Sub-section 4 runs:—

"A body corporate, and in Scotland a firm or partnership, may carry on the business of a pharmaceutical chemist, or chemist and druggist—

"(a) if the business of the body corporate, firm, or partnership, so far as it relates to the keeping, retailing and dispensing of poisons, is under the control and management of a superintendent who is a duly registered pharmaceutical chemist or chemist and druggist, whose name has been forwarded to the registrar appointed under the Pharmacy Act, 1852, to be entered by him in a register to be kept for that purpose, and who does not act at the same time in a similar capacity for any other body corporate, firm or partnership; and

"(b) if in every premises where such business as aforesaid is carried on, and is not personally conducted by the superintendent, such business is *bonâ fide* conducted under the direction of the superintendent by a manager or assistant who is a duly regis-

tered pharmaceutical chemist or chemist and druggist, and whose certificate of qualification is conspicuously exhibited in the shop or other place in which he so conducts the business.

"A body corporate, and in Scotland a firm or partnership, may use the description of chemist and druggist, or of chemist or of druggist, or of dispensing chemist or druggist, if the foregoing requirements as to the carrying on of the business are observed, and if the superintendent is a member of the board of directors or other governing body of the body corporate, or of the firm or partnership, as the case may be.

"Subject as aforesaid, Section 12 of the Pharmacy Act, 1852, and Sections 1 and 15 of the Pharmacy Act, 1858, shall apply to a body corporate, and in Scotland to a firm or partnership, in like manner as they apply to an individual."

The necessity for this sub-section arose from the fact that by the decision of the House of Lords in the case of "The Pharmaceutical Society v. the London and Provincial Supply Association, Limited" (Law Reports, 1880, Appeal Cases, 857), corporate bodies were held to be exempt from certain provisions of the Pharmacy Act, 1868, and were able to keep open shop for the sale of poisons without being subject to the regulations for the storage of the same, which are binding upon chemists and druggists.

They could, of course, only actually sell poisons by the hand of a qualified person, but, should they do otherwise, the only remedy was against the assistant selling, who was seldom a man of substance, and consequently against whom penalties could not often be enforced.

It is now provided that in every case a corporate body must have a qualified superintendent of that part of its business which relates to the keeping, retailing, and dispensing of poisons, and, further, if the body corporate wishes to use the description of chemist and druggist, or of chemist or druggist, or of dispensing chemist or druggist, such superintendent must be a member of the board of directors or other governing body of the body corporate.

Further, as in the case of an individual chemist, every branch which is carried on by the corporate body must be under the *bona fide* management of a registered person.

Section 4 confers additional powers with regard to education and examinations upon the Council of the Pharmaceutical Society.

Finally, I would call your attention to Section 5, which provides for some restriction on the sale of certain acids and salts, although it is not thought necessary that their sale should be confined to registered chemists.

It is provided that they shall be labelled with the word "Poisonous," and with the name and address of the seller.

I am conscious of the inadequacy of this rapid review of the Poisons and Pharmacy Act, but I feared overtaxing your forbearance, and I hope it may be sufficient to incite discussion, and that if any point is not clear, I may be given a further opportunity of elucidating it.

## CLINICAL RECORDS.

### PUERPERAL FEVER AND GONORRHOEA.

By A. STAYT DUTTON, L.R.C.P.LOND., M.R.C.S. ENG.

THE following case seems to be worthy of record, not on account of any special features connected with it, but in relation to its cause.

I was asked to visit the patient, a nullipara, æt. 26, by the midwife who attended at her confinement, on the third day following it. On examination I found a temperature of 103.5° F., pulse 120, and the usual feverish symptoms. There was no pain or tenderness over the uterus, and no evident local symptoms, with the exception that there was a considerable amount of a muco-purulent vaginal discharge of an inoffensive character. Between the third and the tenth day the temperature varied between 100° F. and 105° F., and

the pulse between 100 and 140. During this period there were no signs of parametritis or peritonitis, and only slight abdominal pain and tenderness, which were not constant. There were no rigors. For three or four days she was troubled with diarrhœa. On two occasions the temperature rose to 105° F., but on the eleventh day the more severe symptoms had subsided and the temperature was normal.

With regard to the causation, the possible retention of a portion of the placenta or of the membranes was considered, but of this there was no account, nor were either found on digital examination of the uterus. An inspection of the external parts did not reveal a rupture of the perinæum, or any lesion that was likely to have been a centre of infection. With respect to the possible introduction of infection from without, there was no evidence of any neglect, inefficient management, or uncleanness on the part of the midwife, who had used the necessary antiseptics both for herself and for application to the patient all through her attendance. She had not attended any other recent case of puerperal fever. Inquiry was made with regard to the sanitation and hygiene of the house and of the neighbourhood. The house was one of fifty of a moderate size that stood in a row in a high and open country district, and detached by half a mile from the rest of the village. The system of drainage for these dwellings had for some time been considered ineffective. So much was such the case that the occurrence of this illness precipitated the renewal of it, and within a few days of her recovery the work of a fresh system was taken in hand. But although this was so, no connection could be established between the puerperal condition and defects in the sanitary arrangements. An epidemic of scarlet fever had for some time been present in the district, chiefly among children, but the patient had not, as far as she was aware, been brought into contact with anyone affected with it or in whom it subsequently developed. Attention was then directed to other possible sources of infection, and, on investigation, there was a distinct history that a discharge characteristic of gonorrhœa had been present for some months.

Having excluded the more usual determining factors in its onset, this complaint seemed to suggest the probable cause, and on going into the question more fully, I became persuaded that it was. The capability of acquiring puerperal fever through the agency of gonorrhœa is fully recognised, but the general opinion appears to be that it is an event of comparatively infrequent occurrence.

Eden considers that the gonococcus is the only organism which auto-infection can, with anything like certainty, be ascribed to. (a) Galabin states that Whitridge Williams found the gonococcus present in 6.4 per cent. of 125 cases in which the lochia contained microbes, and when the temperature was 101° F., or above; also that Kronig ascertained its presence in 27 per cent. of 179 similar cases. (b) Hart and Barbour record a case of acute peritonitis which appeared to be undoubtedly due to gonorrhœa, the woman developing it on the second day after confinement, and dying in ten days. (c)

The observations which have been made with regard to the subject, as well as such a case that has now been described, seem to accentuate the following points: Firstly, although the connection between the two diseases is uncommon, yet the association of gonorrhœa with pregnancy and the puerperal period often occurs. Secondly, in view of the serious results which may accrue to the mother and to the infant, that an inquiry should be made whenever possible with regard to the presence of a vaginal discharge during pregnancy, or, if there has not been an opportunity, at the time of the confinement. Thirdly, having ascertained the existence of gonorrhœa either in pregnancy, during labour, or after the birth of the child, that the necessary measures for its alleviation should in all instances be established.

The need of diagnosing the affection during these periods may be readily admitted, and it is possible that many cases of puerperal pyrexia for which a definite

(a) "Manual of Midwifery." 1906. P. 381.

(b) "A Manual of Midwifery." 6th Ed. P. 817.

(c) "Manual of Gynecology." 3rd Ed. P. 157.

cause is not assigned are thus occasioned, but it is evident that before attributing an attack of puerperal fever to the gonococcus, every other possible origin of infection should be eliminated.

The treatment which is required in order to arrest gonorrhœa in pregnancy and to prevent the deleterious effects it may produce during labour, or during the puerperium, is found in various works. The chronic variety is the most frequent in pregnant women, and, with regard to it, I may add that I have found the use of an injection night and morning, composed of a pint of hot water, in which  $\frac{1}{4}$  a drachm of zinc sulphate and the same quantity of boric acid are dissolved, in addition to, in some instances, the administration of iron alone, or in combination with quinine, the most efficacious method of procuring its relief. There is also the question of ophthalmia neonatorum, and it may be concluded that, if gonorrhœa was discovered whenever present before the infant's birth, and suitable treatment undertaken, as well as immediate attention to the eyes on the completion of labour, this unfortunate and ocularly destructive disease would be largely prevented.

## OPERATING THEATRES.

### ROYAL FREE HOSPITAL.

**UMBILICAL HERNIA.**—MR. WILLMOTT EVANS operated on a boy, æt. 9, the subject of an umbilical hernia. The patient had suffered from birth from the hernia, and all ordinary methods, pads, and trusses were said to have been tried before the child came under observation. The hernia formed a projection measuring about 2 in. in height when fully distended, and when reduced an opening was felt in the abdominal wall about 1 in. in diameter. Operation had been postponed because the child had suffered from a troublesome cough, but when this had been relieved by treatment, the child was admitted for operation. When the boy had been anæsthetised with chloroform, and the surfaces had been thoroughly cleansed, special care being taken to make the umbilical pit clean by means of an ethereal solution of biniodide of mercury, two curved incisions were made for about 1 in. above the hernia to a corresponding distance below, so as to enclose a portion of skin 4 in. or so in width, which included the umbilicus. The flaps thus marked out were turned back, and the tissues were dissected until the neck of the hernia was laid bare. The contents were then returned into the abdomen and the sac opened. It was found that a small portion of omentum was adherent to the sac wall. This was ligatured in two pieces with silk, and divided. The sac wall was next carefully separated from the abdominal wall, ligatured, and returned into the abdomen, the excess of the sac wall being removed. It was then found that the ring at the neck of the hernia could not readily be closed on account of its rigidity. The abdominal wall was therefore incised in the middle line above and below, dividing the ring; it was then possible to make one side overlap the other. The two edges were now brought together by means of mattress sutures of silk, without any tension, and the skin wound was sutured with catgut and dressed.

Mr. Evans said that it was seldom indeed that umbilical hernia in children required operation. Although it was very common in the first year of life, it was extremely rare to meet with it during the second decade, but it increased in frequency again after the age of 40. There was no doubt, he considered, that the umbilical hernia of infants has a natural tendency to cure, and in most cases recovery occurs whether treatment has been adopted or not. He had little doubt that the use of a suitable pad had a definite effect on the cure of an umbilical hernia, but the pad was so carelessly applied by the parents of most outpatient children, and it was so frequently omitted entirely, that if the cure depended on the proper use of the pad, recovery would be much less common than it was. In the present case the time had gone by to expect a cure without operation. The formation of a hard ring through which the bowel protruded in itself prevented that approximation of the sides of the open-

ing which was essential to a permanent cure. He therefore considered the time had come when operation might be legitimately employed. It was not sufficient, he pointed out, in cases of umbilical hernia merely to remove the sac; the opening itself must be closed. It was unwise, he thought, to attempt to operate on these cases if the child is suffering from cough or from any other condition likely to increase intra-abdominal pressure. The time devoted to the cure of the cough, he considered, would be well spent. The essentials of the operation were: the closure of the umbilical ring, while strict asepsis was of paramount importance. When the ring is recent the sides come together easily, and that was probably what happens in a spontaneous cure; but when years have gone by the substance of the ring thickens into a hard mass, so that it is difficult to bring together the sides of the ring. In such a condition there are two alternatives, he said, before the surgeon. He may either excise the ring or he may divide it above and below, and continue the incision for half or three-quarters of an inch in each direction. By either of these methods it will be found possible to bring together the sides of the opening. Of the two methods, Mr. Evans considered the second to be the better. Attention, he remarked, must also be paid to the method by which the two sides are to be held together; for the best results overlapping was essential, and the mattress stitches were the most suitable; but, above all, it must be borne in mind that there should be no real tension on the stitches, for if there be they will surely cut out.

Nothing need be said about the after progress of the case beyond drawing attention to the fact that great care was taken by bandaging to prevent any straining on the wound beyond the tenth or fourteenth day. When the dressing was removed at the end of a fortnight the wound was soundly healed. Most of the catgut stitches came away with the dressing, but one or two needed division and removal.

## TRANSACTIONS OF SOCIETIES.

### OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.

MEETING HELD IN THE ROOMS OF THE MEDICAL SOCIETY OF LONDON ON FRIDAY, JULY 9TH, 1909.

Mr. PRIESTLEY SMITH in the Chair.

DR. F. W. EDRIDGE GREEN showed a

#### SPECTROSCOPE FOR TESTING COLOUR PERCEPTION.

It is constructed like an ordinary spectroscope, except that there is a telescope and collimator both fixed, and in the focus of the eye-piece there were two shutters. Those cover the whole of the spectrum, and by means of them the operator can isolate any portion of the spectrum, in order to show the size of the patch, which seems to be monochromatic to any person. He said that whereas it used to take him three days to examine a case by the old instrument, he could now examine one in half-an-hour, because attached to each shutter is a drum marked in wave lengths, graduated to the fourth degree, which was very fine. That enables the size of the patch to be determined without any calculation. The spectroscope could be used for seeing the exact termination of the spectrum, and how far the ends extended.

Mr. N. BISHOP HARMAN showed a chart illustrating some new cataract pedigrees. The cases illustrated the truth of Dr. Treacher Collins' contention that the cataract was a defect in the lens secretion which went to make the capsule. The patients had plaques on the back part, behind the nucleus, and including the posterior part of the lens. In one girl the cataract extended so as to include the nucleus, while in a further case it projected forward like a piece of coral through the lens, so that it seemed there was lens matter bulging through. At first, he thought it was that, and that it had been needed, and afterwards got hard and sclerosed.

Mr. ARNOLD LAWSON and Mr. MACKENZIE DAVIDSON read a paper entitled

A PRELIMINARY NOTE ON THE TREATMENT OF EYE DISEASES BY RADIUM.

Mr. LAWSON said the cases had been selected from the out-patient clinique of Moorfields Hospital, and were selected as instances of maladies which usually proved obstinate or only improved slowly under the ordinary forms of treatment, or else were of an active and virulent nature, and so required drastic measures. Only 17 cases had so far been tried, but in every case the result of exposure to radium had been very encouraging. Most of the cases were corneal ulcerations, four were non-ulcerative lesions, and one was episcleritis. After one application of five minutes to a hypopyon there was distinct benefit. For instance, a man, æt. 35, gave a history of injury to the right eye. There was deep ulceration, and a grey infiltrated area of 4 mm. diameter, with a large hypopyon; 20 milligrams of radium were applied for 5 minutes, and five days later the injection was subsiding, and the hypopyon had disappeared. Two days after a second application of three minutes the man was discharged from the hospital, the eye being not quite white, but, for all practical purposes, well. Other cases also did very well from the treatment. In all cases the only other measures were boracic lotion and atropine where required. Some punctate erosions were also similarly treated, and gave equally encouraging results, as also did cases of old-standing trachomatous pannus, except in one case, in which there was increased vascularity after the treatment. The dosage of radium was an important point, and the small dose of 5 milligrams seemed to act as quickly as did a much larger quantity. In one case the pain after the application endured three days, but in the others the longest time was 20 hours. Dr. Mackenzie Davidson explained that the paper was a tentative one. The radium was applied in sealed glass tubes, the glass cutting off the Alpha rays, so that the Beta and Gamma rays only passed through the lesion.

Mr. ERNEST CLARKE and Mr. HEWKLEY discussed the paper.

The CHAIRMAN then, in a graceful tribute, presented to Mr. Edward Nettleship the Nettleship medal for his work in ophthalmology, and Mr. NETTLESHIP replied, paying a high compliment to the many coadjutors who had helped him to complete the pedigree on which he had been working.

MEDICO-LEGAL SOCIETY OF LONDON.

MEETING HELD JUNE 22ND, 1909.

Dr. SCOTT in the Chair.

A PAPER ON

THE POISONS AND PHARMACY ACT

was read by Mr. H. WIPPELL GADD. (This will be found in full on p. 33 of present issue.)

In the discussion that followed,

Dr. STANLEY ATKINSON asked whether the real reason for granting licences under Section 2 of the Act was not that chemists, being used to selling small quantities, charged too much when supplying horticultural poisons? He thought it would be interesting to notice whether in the next report of the Registrar-General there was any increase in the number of suicides and accidental deaths due to poisonous preparations used in agriculture and horticulture.

Mr. R. A. ROBINSON called special attention to Section 5, and the powers given therein to the Privy Council to make regulations as to the sale of mineral acids and soluble salts of oxalic acid. He thought the Medico-Legal Society might usefully make recommendations as to what, in their opinion, such regulations should include. He related an experience of his own, where a virulent preparation of nicotine was exposed for sale by a greengrocer, who was absolutely ignorant of its dangerous nature, and yet applied for a licence to sell poisons.

Dr. HUBERT BISS thought the Act under discussion a most iniquitous statute. All proposed pharmaceutical legislation which had been brought forward

in the interest of the public health had been watered down to suit commercial interests. Company chemists did nothing for pharmacy, but simply sold what they could with least trouble. They were large advertisers, and were, therefore, given the support of the Press. He thought it shameful that the personal title of "chemist" had been given to corporate bodies, whilst the title "pharmacist," which was of no use, because no one understood it, was restricted to individuals.

The CHAIRMAN (Dr. Scott) said, in his opinion, it was a very serious matter to allow persons who were uneducated, or at least had received no professional or technical training, to sell poisonous substances.

Mr. GADD, in reply, thanked the meeting for its very kind reception of his paper. He would have answered Dr. Atkinson's remarks had not Dr. Biss so effectively replied to them.

## CORRESPONDENCE.

### FROM OUR SPECIAL CORRESPONDENTS ABROAD.

#### FRANCE.

Paris, July 11th, 1909.

#### ARTERIO-SCLEROSIS TREATMENT.

It is generally believed that arterio-sclerosis is a malady of old age. Such is not the case. It can be observed, according to Prof. Huchard, in his paper read at the Geneva Congress, between 30 and 60 years of age; and Lancereaux published several cases between 30 and 40; but it is from 40 to 50 years that this affection is the most frequently observed. Death supervenes, in one form or another, between the ages of 50 and 65, this latter representing in most cases the extreme limit.

Arterio-sclerosis may be regarded, consequently, as a disease of ripe age, but, in reality, it reveals premature decline. Vigour, energy, good health, food, do not always correspond to the number of years. To say rightly, a man is more the age of his arteries (Casalis) than of his birth register. Atheroma of the blood-vessels is the cause of profound disorder in all the economy. The blood-vessels of arthritic individuals, writes Fernet, age early, and all the organs suffer from defective irrigation.

Arterio-sclerosis is the great cause of angina pectoris and apoplexy, and renders particularly grave certain infectious maladies, as grippe and pneumonia. It is consequently of primary importance to recognise the first signs of the disease before the arteries have become thickened and have lost their elasticity, for afterwards all treatment would be useless.

The practitioner, says M. Lancereaux, will not forget that if he does not succeed in curing arterio-sclerosis he will have one day or another to treat the serious disorders which result from it: functional insufficiency of the kidney (uræmia), or that of the heart (asystole), and also frequently cerebral manifestations.

The first symptoms of this malady are revealed by oppression in walking, headache, palpitation, vague pains, cramps, stitch in the side, præcordial anguish.

The pulse is hard, the heart-sounds sharp, especially the second, and all these symptoms become aggravated as the malady progresses. The patient complains of somnolence in the day, at night sleep is agitated, while polyuria is present in most cases. Symptoms of hypertension (epistaxis, divers congestions, etc.) are frequently observed, and the superficial arteries, radial, temporal, are hard and sinous.

Sometimes arterio-sclerosis affects particularly the nervous system, as described by Jacquet, of Bâle. The disorders are manifested by a change in the character; the patient becomes irritable, is easily fatigued, incapable of concentrating his attention on any subject for a certain time. Memory fails, especially as regards names and numbers, and these troubles are complicated with headache and vertigo.

The headache generally occupies the frontal region; it is less an acute pain than a kind of painful pressure. The patients complain of their heads being fixed, as it were, in a vice, and this sensation may persist for long periods. Vertigo is generally spontaneous, or it appears during a sudden change of position, such as

getting out of bed, or physical or intellectual effort. The patients frequently complain of noises in the ears, while intolerance for even small doses of alcohol is characteristic.

Patients are quite conscious of their condition, suffer accordingly, and frequently express their fear of softening of the brain.

This condition is susceptible of improvement, but generally remains stationary for years, and death is finally caused by apoplexy, sclerosis of the coronary arteries, or some other intercurrent malady.

This particular form of arterio-sclerosis is frequently confounded with neurasthenia, and this confusion may cause erroneous treatment.

What should be the treatment prescribed for the patient? The classical iodide of potassium has fallen out of favour.

For Dr. Huchard the iodide treatment is not only useless, but hurtful, during the pre-sclerosis period, as well as in the third and fourth period, when renal and cardiac insufficiency have to be treated.

The use of iodide of potassium has been found to be sometimes attended with such accidents as oedema of the glottis or of the lungs, especially in renal and aortic disease. Dr. Huchard also protests against the treatment by serums, trinitrine, nitrite of amyl, electricity, etc., which all of them possess but a hypothetical influence on arterial hypertension, which in reality might be regarded as a secondary element of the malady.

The real cause of arterio-sclerosis is not very clear. Alcohol and tobacco were incriminated, but unjustly, according to Lancereaux. Arthritism as a predisposing cause is generally admitted, as well as those affections which tend to lower the nutrition. It is probable that the presence of an excess of uric acid in the blood is one of the chief factors in the disease, or, in the words of Prof. Huchard, "gout is to the arteries what rheumatism is to the heart."

The rational treatment, consequently, affirms Dr. Marc-Frenkel, of arterio-sclerosis, consists in disintoxicating the patients by the use of dissolvents of uric acid. Over 40 cases were treated successfully by Dr. Frenkel with urodonal, a recent drug, considered to be the most powerful dissolvent of the acid, at the dose of a teaspoonful in a little water, four times a day between meals, for ten days every month. Under this treatment the arterial tension was notably lowered, while the phenomena of congestion (epistaxis, præcordial oppression, neuralgic stitches in the side), disappeared, and the patients recovered their ordinary sleep and lost all diurnal somnolence.

Besides the medical treatment, certain foods should be proscribed: high meat or cheese, fish, strong wines, kidney beans, sweet-bread, etc. Another advantage of this treatment by urodonal is that it is inoffensive even in renal insufficiency.

#### ARTHRITIC NODES OF THE FINGERS.

Iodide of sodium	} 1 dr.
Nitrate of soda	
Salicylate of soda	
Acetate of potash	
Water, 8 oz.	

A dessertspoonful at each meal (3) in a little water. The treatment should be continued six months, with an interval of rest of a week after the end of each bottle.

#### WRINKLES.

Milk of almonds, 2 oz.  
Sulphate of aluminium, 1 dr.  
Rose water, 6 oz.

To be applied at bed time. A good massage of the wrinkled surface should precede the lotion.

#### GERMANY.

Berlin, Ju'y 11th, 1909.

At the Verein für Innere Medizin, Hr. Bleichroeder related particulars of a case of

#### ENORMOUS CYSTS OF THE KIDNEYS.

The patient, a woman, was admitted into hospital suffering from severe bronchitis, and died soon after admission from cardiac failure. At the autopsy enormous cysts of the kidneys were found. The curious feature was that there had been no evidences of renal

mischiefs during life, or any disturbances of the circulation; there had been no uræmia. In answer to a question by Hr. Kraus, the speaker said that tumours had been felt in the abdomen during life, but no diagnosis had been made as to their nature.

Hr. Payr, Greifswald, gave an address on

#### THE PATHOGENESIS AND TREATMENT OF ULCER OF THE STOMACH.

Amongst the numerous attempts to explain the causation of the disease, he said that which found the most favour was that of self-digestion set up by some kind of circulatory disturbance (Virchow-Pavy). According to his own earlier experiments, blocking of a considerable area of the stomach by injection of China ink, or emulsion of dermatol into the vessels, invariably gave rise to hæmorrhage into the mesentery, with erosion and ulceration of the walls of the stomach.

These, rather quickly healing ulcers, would be more correctly described as corrosion defects, just as attempts to set up changes in the human subject, similar to the changes of *ulcus rotundum*, had only succeeded in producing traumatic defects. It was only very exceptionally that ulcers formed showing no tendency to heal (Fütterer).

The speaker had now succeeded in producing all possible forms of ulcer of the stomach by injecting weak formaline solutions, diluted alcohol, into the vessels of the stomach walls, with or without simultaneous lesions of the mucous membrane, those with hard callous edges, as well as those that perforated into the abdominal cavity. In his opinion the chief cause of want of any proclivity to heal lay in extensive changes in the walls of the blood-vessels of the stomach, in sclerosis and puckering around the base of the ulcer.

From this observation he had drawn conclusions as regarded treatment. After a short description of the complications met with in ulcer of the stomach, he passed on to treatment.

Simple ulcer belonged to internal treatment. Not only did the so-called "classic" complications of ulcer demand surgical interference—hæmorrhage, perforation, and stenosis—but also callous ulcers, tumour ulcers, as they defied treatment, or returned after improvement.

Independent of operative treatment of perforative ulcer, and for excessive hæmorrhages, there was at present a rivalry between gastro-enterostomy and resection of the ulcer.

The first-named was at present the normal method for the majority of surgeons. The latter was deserving of being more used in ulcers of the body of the stomach. Like Riedel, he was also in favour of circular (transverse) resection. He had treated 21 cases of ulcer of the stomach by excision or resection, and had only 1 death to record.

At the close of his address he showed two patients on whom he had operated by resection for ulcer of the stomach with tumour (*Ulcustumoren*), removing extensive sections of stomach wall. Both were now in perfect health.

Hr. Rosenheim agreed with the giver of the address as to the pathogenesis. As regarded the question as to the frequency of cancer formation, enormous figures had been given, but wrongly. Some years ago he had given 6 to 7 per cent.; Virchow had opposed him, and given the percentage as 2 to 3. But Virchow had only seen the termination of the process, and at that stage the traces of the genesis had often disappeared. He now thought 6 to 7 per cent. too low; he would place it at 10. He quite agreed with Payr as to treatment. His mortality with resections had been 5 per cent.

Hr. Kraus gave statistics taken from a prize essay that had been submitted to him. According to this, out of 600 persons that had undergone gastro-enterostomy, only 1.10 per cent. had died from carcinoma. From this it would appear that the dread of cancer should not lead to the selection of gastro-enterostomy as opposed to resection. It was interesting that Brenner found carcinoma in the cicatrix after resection, and, curiously, also in the percentage of 1.10.

Hr. Bickel had seen duodenal ulcers after gastro-enterostomy. The disappearance of the disease with advancing pregnancy was probably due to gastric secretion becoming diminished at this stage.

Hr. Katzenstein laid stress on the great importance of Payr's experiments, but said they did not explain why ulcer of the stomach had so little tendency to heal. After operation (he preferred gastro-enterostomy to resection), the diet he recommended was a necessity.

### AUSTRIA.

Vienna, July 11th, 1909.

#### HISTORY OF SYPHILIS.

At the Gesellschaft der Aerzte, Kronfeld startled the members with a history of syphilis which, he affirms, commenced *seven or eight hundred years* before the birth of Christ. We were always told at school that Columbus was the licentiate that inflicted this disease on mankind. We now learn that that daring explorer has been maligned, and that a young woman of the negro type has all the marks of the evil one. It seems that Kronfeld combines painting with medicine, and in his pursuit as a painter has devoted a considerable time to morbid diseases among the ancients. In his devotion to medicine he has discovered an ancient piece of sculpture in the Austrian Museum for Art and Industry that conclusively proves that syphilis was common among the Greeks seven or eight hundred years before the birth of Christ.

The subject of investigation is on a vase still in good preservation. On this vase are two figures, having the titles inscribed, "*Ungerechtigkeit*" and "*Rechtigkeit*," the former having a distinct negro type, while the latter was spotless and without a blemish, the former has large chronic serpiginous ulcers on both legs and arms, that no practised eye can doubt the nature of the disease. The ulcers on the body may be confused with lepra, but their serpiginous form, raised, sharp-cut edges, are strongly presumptive of syphilis. The "*Rechtigkeit*" is supposed to have been put to death for her chastity, and is represented in the figure as purity itself. Kronfeld cannot believe that this disease had an epoch of explosion, nor that this is an isolated case in the art.

In Darmstadt there is another old bronze figure with the same disease depicted on the arms and hands; sharp, depressed ulcers, circular and serpiginous, and resembling the "*Ungerechtigkeit*" in every detail. The absence of these chronic diseases in Grecian art in general is no proof that syphilis did not exist, as the Grecian was always in favour of depicting perfection, and not blemishes.

It was suggested, he said, that these ulcers on the "*Ungerechtigkeit*" were the result of tattooing, but it must be borne in mind that tattooing was rare amongst the ancients, but even tattooing can be distinguished from these chronic serpiginous ulcers. He next quoted from ancient medicine, historians and poets to prove that Columbus was innocent of the crime attributed to him.

Hovorka said the origin of syphilis always seemed to him to be one of self-righteousness—everyone blamed his neighbour! The French used to call it "*Mal Espagnol*," "*Mal Anglais*," "*Mal Indien*," "*Mal Portugais*," while the Spaniards called it "*El mal Francez*"; the Portuguese, "*El mal Castellano*"; in Italy it was called "*Mal di Spagna*"; in Germany, "*Spanische*," "*Litannische*," "*Lothesingische*," and "*Franzosen Krankheit*"; in England it was long known as "*The Spanish Sickness*," and even the Turks called it the "*Christian Disease*"—everyone but themselves were to blame for creating this vile offence among the pure and righteous!

It seems to be a universal disease, and one whose medical treatment has passed through many phases, which may briefly be divided into mineral and vegetable. Popular domestic medicines appear to have been used before the recognised physician commenced with mercury, copper, etc. Mercury was first extensively used in the West Indies; Turkey and China using cinnabar; Russia and Bosnia in the form of vapour, and dusting the sores. Calomel with a vegetable infusion appears to have been early used by the Chinese; thereafter Turkey and Russia used it as

an external application. Sublimate was used in Siberia long before syphilis was reported in Europe, and copper filings in South Africa, all claiming a specific for the mysterious disease. Vegetable decoctions, as sarsaparilla, guaiacum wood, China root, smilax, etc., were among the favourite drugs to combat the disease. From the history of the apothecary we learn that syphilis was an early plague of mankind that probably flowed and ebbed according to leisure and luxury.

Ehrmann brought forward documentary evidence to prove the American origin of the disease. It appears to have presented itself quite suddenly, as Cataneus writes of it:—"*Morbus insolitus, nullis antea saeculis visus*," which he goes on to say is very destructive and epidemic. Dürer, of Venice, tells us that an attack ensures immunity, and inoculation modifies the attack, although mercury seems to have been freely administered. It may be noted here that mercury was used early by the Moors in Spain for scabies, which would lead to the use of the drug in the new disease, and as warfare was common in those times, the Italian and Venetian surgeons would early follow their example.

## FROM OUR SPECIAL CORRESPONDENTS AT HOME.

### SCOTLAND.

MEMORIAL TO THE LATE DR. FINLAYSON, GLASGOW.—On behalf of the committee of subscribers to the fund in memory of the late Dr. James Finlayson, Sir Hector Cameron has presented to the Council of the Faculty of Physicians and Surgeons of Glasgow a deed of gift conveying to the Council the future management of the funds. The income of the fund is to be applied to the endowment of a "Finlayson Memorial Lecture-ship," the lecturers to deal with some branch of pathology, medicine, or the history of medicine.

TREATMENT OF PHTHISIS IN EDINBURGH.—The results of the system of isolating cases of advanced phthisis, which would otherwise form dangerous foci of infection, having proved satisfactory, the Town Council has resolved to extend the accommodation provided in the Edinburgh Fever Hospital from 50 to 62 beds. It is proposed to erect six pavilions of 12 beds each, and the estimated annual additional cost of maintenance is put at £250.

GLASGOW ROYAL INFIRMARY.—The Lord Provost of Glasgow opened the new surgical block of the Infirmary on June 23rd, and in congratulating the managers on the progress made in their scheme of reconstruction, stated that the next portions to be proceeded with were the third wing of the surgical wards, the isolation department, the pathological department, and the block for special diseases. The probable cost of the alterations is estimated at about half a million, towards which £320,000 has been raised.

PRESENTATION TO PROFESSOR CLELAND, GLASGOW.—On the occasion of his retirement from the Chair of Anatomy, Professor Cleland was presented by the medical students of the University with a handsome carriage clock. The proceedings took place on June 25th in the University Union, and the presentation was made on behalf of the students by Mr. Galbraith, President of the S.R.C.

FIRE AT PEEBLESHIRE FEVER HOSPITAL.—The central building of this hospital was completely destroyed by fire on the night of July 8th. There were 20 patients in the hospital at the time, and these were all safely removed and accommodated in the Poor-house on the opposite side of the road. The fire was extinguished in about two and a-half hours, the wings of the hospital, in which the wards are situated, being saved, but the central administrative block, which is built of wood and corrugated iron, was completely burned to the ground.

### BELFAST.

ULSTER MEDICAL SOCIETY.—The annual meeting of this Society was held in the Medical Institute, Belfast, on Thursday evening, July 8th, the President, Mr. T. S. Kirk, in the chair. The minutes of the last

annual meeting having been read and confirmed, the report of Council was presented, with the Hon. Secretary's, Treasurer's, and Librarian's reports. These showed the Society to be in a flourishing state, the Treasurer having a balance of £73 in hand, notwithstanding some exceptional expenditure.

These reports having been adopted, Dr. Calwell moved that the Hon. Secretary be instructed to consult with the Hon. Secretaries of the Belfast Division and Ulster Branch, British Medical Association, and arrange at the commencement of each year the dates of ordinary meetings for the year, and see that these dates are notified to Fellows and Members. This resolution was passed.

The following were elected office-bearers for 1909-10: President, Dr. Austin; Vice-Presidents, Dr. Darnell (Bangor) and Dr. Maguire; Hon. Secretary, Dr. Howard Stevenson; Hon. Treasurer, Dr. Fieldin; Hon. Librarian, Dr. Storey. A committee was appointed to draw up the deed of gift of the Belfast Cup, which the golfing members of the Society are presenting to the British Medical Association, to be played for at the forthcoming meeting of the Association in Belfast.

Through Dr. John McCaw, a very beautiful copy of an address was presented to the Society, the original having been presented to Dr. Coffey in 1839 by the members of his class in surgery, on the occasion of his retirement from his chair in the old Belfast College. It was through Dr. Coffey's influence that his favourite pupil, Dr. Alexander Gordon, was appointed his successor.

## LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

### THE REMOVAL OF GROWTHS FROM THE VOCAL CORDS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Dr. Dundas Grant, in his letter of July 7th, points out that in the report of my remarks in connection with the removal of a laryngeal growth by direct vision laryngoscopy, justice was scarcely done to the older indirect mirror method of removal with angular forceps. I, of course, agree with him that it has often been possible for experts to remove favourably situated laryngeal neoplasms at one sitting by the indirect method, not only with, but even without, cocaine anaesthesia, as in the early operations of Czermak and Mackenzie.

My remarks, however, were made in reference to a growth unfavourably placed—viz., springing from the anterior fourth of the left vocal; the exact point of origin was not sufficiently brought out in the report. Dr. Grant will probably endorse my observation "that the removal of growths in the near neighbourhood of the anterior commissure was always difficult under the old indirect mirror and forceps method, and often necessitated a large number of sittings to train the patient to toleration."

Your reporter has given an excellent summary of my remarks to him. If, however, I had had an opportunity of revising his notes in manuscript or in "proof," it is not unlikely that I should have more definitely acknowledged the remarkable results sometimes achieved in the past by experts, in spite of the difficulties incidental to the indirect method. After considerable experience with both methods, I am, however, convinced that the direct one enables us to remove even a favourably situated growth more easily, certainly, and thoroughly than the old method with the mirror and angular forceps; and as for cases which present difficulties, whether due to site or size of the growth, or to the sensitiveness or to the age of the patient or what not, the superiority of the new method cannot be seriously questioned; and it moreover possesses the enormous advantage of being easily carried out (by an expert) under deep chloroform anaesthesia, if necessary. For my own part, having mastered the technique of direct vision endo-laryngeal handicraftsmanship, it is quite a relief to me to feel that I shall

rarely be annoyed again by failure to remove a laryngeal growth at one sitting, or at the most two sittings, in the case of difficult multiple neoplasms.

In spite of Dr. Grant's loyalty to the older method, in which he is so expert, I feel very confident that his increasing experience in dealing with large, tough, tubercular growths through the direct laryngeal spatula will before very long lead him to adopt the latter method almost exclusively in other endo-laryngeal surgical procedures.

I am, Sir, yours truly,

WILLIAM HILL.

26 Weymouth Street, London, W.,

July 11th, 1909.

### EMOLUMENTS OF CHRISTIAN SCIENCE.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—“Science and Health” is published at a price which is not in the least extravagant, and I have never known a single person who has not been able to obtain it without difficulty. Dr. Sers suggests that the price of the book is kept up for mercenary purposes. Only last week a correspondent wrote objecting that he could not obtain a copy of “Science and Health” in a foreign language, and asking why its circulation was prohibited by a refusal to have it translated into foreign languages. If the aim of the publishers of “Science and Health” is to make money out of it, imagine the enormous amount of revenue they are cutting off by refusing to have it translated into other languages; and, in precisely the same way, if their object is to make money, how could they make money better than by flooding the world with cheap editions? Furthermore, there is attached to every Christian Science church a free circulating library, from which every prospective purchaser of “Science and Health” can borrow it for nothing. I am not aware that the publishers of Farrar's “Life of Christ,” or Renan's “Life of Jesus,” to take the two examples selected by Dr. Sers himself, ever opened their doors to the public and said, “You can come and borrow these books for nothing, and read them, and afterwards buy them or not, as you may desire.” The reasons for publishing “Science and Health” at its present price, which is a perfectly modest one, are the business of the Christian Science Church alone. It should be perfectly possible to differ absolutely from your neighbour, without it being necessary to impute either ignorance, fraud, or greed.

I am, Sir, yours truly,

FREDERICK DIXON.

July 3rd, 1909.

[At Mr. Dixon's urgent request we print the essential parts of his very long letter. Those who have studied Mr. Dixon will not be surprised to find that he does not yet recognise that his writings serve merely to bring ridicule upon the cause he champions; at least, when he addresses scientific readers. Christian Science professes to cure all diseases by prayer, and by practice of the cult by agents who, mostly, make an income out of it. If its claims could be in any way substantiated crowds of unpaid missionaries would be forthcoming to carry its benefits to suffering humanity throughout the world. Mr. Dixon, however, tells us that, lest they should be charged with mercenary motives, Christian Scientists refuse to issue their works in foreign languages, thus depriving foreigners of the blessings so near their reach. The whole thing is too childish for argument; and neither now nor in future can we give more space to it.—ED. M. P. AND C.]

## OBITUARY.

ANDREW JAMES DUNCAN, M.D. Ed.

WE regret to record that Dr. Andrew James Duncan, of Dundee, died at his residence on July 7th. A stroke of paralysis had laid him low, and, in spite of every effort to promote recovery, the attack proved fatal. By his death there is removed one of the foremost medical practitioners of the city. He had a large

*clientelle*, representative of all classes of the citizens, and was recognised as a skilful and careful physician. He was born in India, his father being Dr. Andrew Duncan, of the Honourable East India Company's service. He was brought up in Dundee, and was educated in the city and at Edinburgh University. After graduating M.D. at Edinburgh in 1865, he studied at Vienna and Paris, and commenced the practice of his profession in Dundee in 1866. Since then his life has been spent in the city. He soon gained the confidence of the public, and his practice extended rapidly. All his energies and time were devoted to his work. He was, however, deeply interested in the Infirmary, of which he was a director for some time, and up to his death he was an honorary consulting physician of the institution, as well as being at one time honorary ophthalmic surgeon. Amongst other appointments held by him were those of surgeon of the Eye Institution and surgeon of the Institution for the Blind.

## SPECIAL ARTICLES.

### SIXTEENTH INTERNATIONAL CONGRESS OF MEDICINE, BUDA-PESTH, AUG. 29th—SEPT 4th.

THE travelling arrangements to and from the Budapest Congress have now been issued, and the *carte d'identité* enabling members to obtain certain reductions in the fare has been sent to everyone who has paid his subscription. The official reductions are 50 per cent. on the French lines if application is made at least three days before the ticket is required upon the pink form issued. This form must be stamped at the Congress before it is available for the return journey. The Royal Hungarian State Railways make a reduction of 50 per cent. to members furnished with the green card of identity, and there is a similar reduction on the Danube boats. But it appears from the instructions issued that very few members of the British section will be able to obtain these reductions without breaking the journey at each frontier, as it has been found impossible to establish any system of through tickets at reduced rates.

The Great Eastern Railway Company will issue circular tickets as follows:—London, Harwich, Hook of Holland, Rotterdam, Cologne, Mayence, Frankfort-on-Maine, Passau, Linz, Vienna, Budapest; Vienna, Dresden, Hanover, Salzbergen, Hook of Holland, Harwich and London. The cost of these tickets is £10 14s. 5d. issued singly, or £8 2s. 11d. if issued to parties of twenty and to Vienna only. They are available for 90 days, second-class rail in England, first-class on the G.E.R. steamers, second-class rail on the Continent, and first-class on the Rhine steamers, or second-class rail between Cologne and Mayence. By the night service, leaving Liverpool Street at 8.30 p.m., there is a through carriage with a restaurant car from the Hook of Holland to Frankfort (5.48 a.m. to 4.10 p.m.), and a sleeping car (extra fare) from Frankfort to Vienna (4.37 p.m. to 7.30 a.m.). If the journey is taken *via* Dresden, there is a through carriage with a restaurant car from the Hook of Holland to Hanover (5.25 a.m. to 3.5 p.m.); a through carriage with a restaurant car from Hanover to Leipsic (3.5 p.m. to 10.2 p.m.), and a sleeping car (extra fare) from Dresden to Vienna (10.2 p.m. to 7.40 a.m.).

Mr. J. Y. W. Macalister issues a circular from the Royal Society of Medicine, 20 Hanover Square, W., stating that he has organised a party for the Fellows of the Royal Society of Medicine and for the friends of Fellows, although they are not connected with the Society, who are properly vouched for. This party will be accompanied by an experienced courier. It will travel by the *train-de-luxe* both on the outward and homeward journeys, and will be lodged in the best hotels. The inclusive charge is 36 guineas *via* Ostend, and 38 guineas *via* Calais. A deposit of £5 is required, and names are to be sent in at once.

The South-Eastern and Chatham Railway Company quote specially reduced rates for parties of not less than 20 passengers travelling together on the outward journey, but will make no reduction to members travel-

ling individually. The Zeeland Steamship Company, which runs through carriages from Flushing to Vienna in connection with the day and night services from Victoria to Queenboro', will also allow a reduction on the ordinary fares for parties of twenty who travel together.

## REVIEWS OF BOOKS.

### OXYGEN AND SPARTEINE IN ATHLETICS AND TRAINING. (a)

THIS claims to be a contribution to the physiology of Doping. So little is said concerning the use of sparteine that it is difficult to see what are the grounds for its inclusion on the title page. After a brief discussion as to whether the use of oxygen and sparteine can be defended on ethical grounds the author reproduces an article in which his inquiries and experiments upon the administration of oxygen to some few cyclists in France are set forth. The matter is very simply explained, in fact just those difficulties which meet one in facing the subject are omitted, and the author's deductions are equally simple. With all respect it cannot be said that any great addition is made to what already is known on the subject.

### DISEASES OF THE EAR. (b)

A REVISED English edition of the late Professor Politzer's classical work constitutes an event of no little importance in the domain of British otology, for by common consent the author throughout his life held the leading place in the speciality which he may almost be said to have created. No aural surgeon can afford to neglect the views and opinions of the master, and the real question is, whether practitioners in any other line of medicine can dispense with a book which marks the acme of the science of otology. That is for them to decide, but we may say in passing that they will find nowhere in present-day aural literature a treatise so complete, so adequate, and so satisfactory. The anatomy and physiology of the sound-conducting apparatus—the external and middle ears, the Eustachian tube and mastoid process—occupy sixty-five pages, and all the minutiae are entered into fully; whilst the anatomy and physiology of the sound-perceiving apparatus bring the number of these preliminary pages to nearly a hundred. Nearly another hundred are devoted to the methods of physically examining the organ of hearing, and the elaborate care with which each method is described and explained will leave little to the imagination of a practitioner who wishes to render himself *au fait* with the *technique* of modern processes. At the close of this part of the subject the author makes some interesting remarks about the hygiene of the ear. He is convinced that acute suppurative middle-ear affections are much more common in town than in country dwellers, and he thinks that physicians should teach industrial workers, especially those exposed to dust, to wash out the nose with saline solution two or three times a week. Coming to diseases of the ear which, with related maladies of the nose and throat, occupy the remaining six hundred pages, we find a great deal of valuable and sometimes out-of-the-way information which Professor Politzer accumulated during the course of his vast experience. In some respects he is inclined to take a more gloomy view of slight derangements than is customary in this country, his estimate, for instance, that ceruminous plugs in the external auditory meatus, are so frequently associated with organic changes in the middle-ear and labyrinth, seems to lay too much stress on what is commonly a purely local affection. Needless to say, much space is devoted to chronic middle-ear disease and its complications, and here the author is certainly more

(a) "Oxygen and Sparteine in Athletics and Training." By Oscar Jennings, M.D., Paris. London: Bailliere, Tindall and Cox. Price 1s. net.

(b) "Diseases of the Ear." By Professor Adam Politzer, of Vienna. Translated and Edited by Milton J. Ballin, Ph.B., M.D., Assistant Surgeon to the New York Ophthalmic and Aural Institute and to the Mount Sinai Dispensary, Ear, Nose, and Throat Department, and by Clarence L. Heller, M.D. Fifth Edition. Revised and enlarged. London: Bailliere, Tindall and Cox, 1909. Pp. xvi. + 897. 337 illustrations. 25s. net.

conservative in his recommendations than most aural surgeons. A particularly pleasing feature of this book is the credit given to native and foreign otologists who have done good work and advanced the science they are interested in. Professor Politzer always attempting to give credit where credit is due. Excluding all treatises and papers mentioned in the body of the work, his bibliography, which extends to twenty pages and includes papers written between 1733 and 1908, shows the catholicity of his reading and study. Indeed, it is difficult to say more than is justified of this encyclopædic work.

#### SPRAINS AND ALLIED INJURIES. (a)

MR. WHITELOCKE'S book on "Sprains" is the product of a long and rather special experience in the minor injuries which accompany the pursuit of athletics, but it is none the less applicable to similar conditions occurring every day in the course of ordinary life. It is a very practical clinical work. Mr. Whitelocke has, happily, not been content to deal with his cases in the way he learnt in his student days, but has brought to bear on the problems set him in practice an original and inquiring mind. He has treated his patients' injuries as definite surgical entities which have resulted from anatomical derangements, and has thought out how these derangements may be restored. In consequence he has evolved methods of practice new, interesting, and effective, and he deserves immense credit for his ingenuity and skill. No detail is too trivial for notice, and no method of treatment too simple, if it accomplishes the end. As examples of the latter proposition we may cite his plans for dealing with an ordinary sprain of a joint and for replacing a slipped cartilage in the knee. Cold and heat, the traditional variants, in the treatment of sprains, he eschews, in favour of elastic pressure, obtained by wrapping the joint thickly in cotton-wool and bandaging firmly over it. Those who have practised this treatment will find it not only much more efficacious as regards cure, but much more comforting to the patient. As regards slipped cartilages, Mr. Whitelocke observed that the motion of the knee in swimming was the same as that required for reduction of the internal cartilage, and, before trying any further treatment, he makes his patients lie on the floor of his consulting-room and swim vigorously on the carpet. If success does not follow, then he is prepared with a method of reduction by movements which he describes fully and illustrates by photographs. We think the author has done himself a little injustice in not widening the title of his work, for he gives a good deal of information about his methods of operating on joints, and other subjects, such as rupture of muscles, which is of much value, and which the ordinary reader would not, in the ordinary course, come to a work with this title to look for. We greatly dislike the word "system" in connection with surgery, but Mr. Whitelocke's methods of treatment are so original as almost to constitute a new "system" of treatment in the injuries of which his book deals, and we hasten to add that they are much more efficacious than those publicly advocated by any other surgeon, with the exception of Sir William Bennett. Practitioners who do not like to see their patients drift off to bone-setters and electrical quacks, through disgust at the inefficacy of surgery to deal with their sprains, and by such drifting run the risk of life-long injury, will hasten to make themselves acquainted with the contents of this admirable book.

#### DISORDERS AND DISEASES OF CHILDHOOD. (b)

DR. STILL'S new work is a noteworthy contribution to the literature of diseases of children. Its outstanding merits are two: it is based on the large personal experience of the author, and the subject is dealt with from the clinical standpoint. In his preface Dr. Still disclaims any idea of competing with the systematic text-books, but, as a matter of fact, he has

left out little that is of importance, though, curiously enough (and the omission is to be regretted), he does not seem anywhere to describe that form of arthritis with which his own name is now generally associated. In a short review it is impossible to refer at length to the interesting observations with which the book bristles, but we may draw special attention to the chapters on certain clinical groups of symptoms and morbid conditions which are interpolated among the more formal descriptions of stock subjects. Instances of these are the chapters on abdominal pain in children past the age of infancy; on the medical aspects of dental caries; on "bilious attacks," so-called; on fever of obscure causation, and the like. These chapters will be found both practical and extremely interesting, discussing, as they do, subjects which are often a matter of perplexity to the practitioner, and on which most text-books give rather scanty information. They display Dr. Still's powers of observation, and his critical acumen, and his originality, to an extent which is impossible when he is dealing with more hackneyed subjects. In regard to dentition, Dr. Still points out that it occasionally oversteps physiological limits, and may be a cause of fever, of indigestion, or other symptoms—a view in which we heartily concur. We notice that in several places he lays stress on the necessity for boiling milk on account of the risk of tuberculous infection. In this respect his opinion has—as he admits—undergone a change, and we are glad to see that he no longer advocates the use of raw milk. One of the many small points of interest brought out is the fact that in some marasmic babies the use of sodium citrate is apt to cause oedema. The chapter on threadworms is also full of novel ideas; the cases cited in support of the notion that appendicular pain may be caused by the lodgment of oxyurides in the appendix are very suggestive. It would require a long review to do full justice to this most interesting volume, and we must content ourselves by urging practitioners to study its pages for themselves, in the full assurance that they will not regret doing so. Alike by its originality, its practical character, and its perspicacity, it is a most thoroughly satisfactory book. Dr. Still has obviously put an enormous amount of work into its production, and he may be most heartily congratulated on the result.

#### HOUSE DRAINAGE AND SEWAGE DISPOSAL. (a)

WE welcome under the above title and in book form the Cavendish Lectures delivered in February, 1909. While containing no strikingly original statement, the lectures are a mastery summary of the most recent and important knowledge in regard to the subject of which they treat. The style is clear and vigorous, and the author's meaning is never in doubt; in fact, by making the best use of the English language, Dr. Parkes has produced what should serve as a model for those who wish to enter the field of scientific literature.

In spite, however, of the excellence of the work, there are a few points to which exception must be taken; for instance, on page 41 the author justly deprecates any attempt to dogmatise as to the length of time that the typhoid bacillus can exist in a saprophytic condition, and yet on page 21 he refers in detail to experiments from which definite conclusions in this connection have been drawn, while Koch's views—which are presumably reliable and certainly not dogmatic—are not even mentioned.

Again, on pages 101, 102, 103 the advantages of land treatment are clearly stated, including Dr. Houston's finding that, after such treatment, some effluents might be regarded as potable water of more than average quality; and as a like result is utterly unobtainable by other processes commonly in vogue—the processes in question really obviating nuisance rather than danger—it might naturally be assumed that land treatment is the goal at which we should aim. In view of the above, it is rather surprising to find on page 107 that land treatment receives somewhat contemptuous reference. It is stated that "on the whole, the idea that the land is in all cases the best, because

(a) "Sprains and Allied Injuries of Joints." By E. H. Anglin Whitelocke, M.B.Ed., F.R.C.S., Ass.-Surgeon to the Radcliffe Infirmary, Oxford, Litchfield Lecturer in Surgery in the University of Oxford. Oxford Medical Manuals. 1909.

(b) "Common Disorders and Diseases of Childhood." By George Frederic Still, M.A., M.D.Cantab. 8vo. Pp. xii. and 731. London: Henry Frowde and Hodder and Stoughton. 1909.

(a) "House-Drainage, Sewerage, and Sewage Disposal in Relation to Health." By Louis C. Parkes, M.D., D.P.H. London: H. K. Lewis. 1909.

the most natural material for the treatment of town sewage has now been abandoned"—it may be observed with absolute truth that no person of average intelligence ever held any such views regarding the universal applicability of land, as the exercise of even a modicum of common sense tells us that land treatment cannot "in all cases" be the best; but this conclusion does not alter the fact that the waste of sewage entailed by our present systems, including expense of plant and upkeep, is represented by an annual loss of many thousands of pounds, while the actual causes of disease—viz., pathogenic germs—are to all intents and purposes unaffected. Dr. Houston's report for the Royal Commission on Sewage Disposal (Second Report, 1902) leaves no doubt as to the failure of septic tanks, contact beds, etc., to deal with germs of the nature just referred to, so that this particular point can be considered as definitely settled; and it may here be incidentally observed that it is a matter of deep regret that Dr. Houston's dictum cannot be forcibly thrust before public attention, particularly at a time when glaring social abuses appear to stand some reasonable chance of remedy. A far more extensive use of natural agencies would be adopted if it were not for the existence of what are known by courtesy as "vested interests," or, in plain English, as the obstructiveness of private landowners. We would in this matter have heartily welcomed the force which Dr. Parkes' authority would lend to the cause of what is unquestionably a neglected sanitary reform, and we therefore regret the opportunity he has lost for rendering service to that branch of medical science of which he is a justly distinguished ornament.

In spite of the existence of what we believe to be defects, we can honestly congratulate Dr. Parkes on a work which should be in the hands, not only of those who are officially connected with sanitation, but of all who are interested in the public health of the country.

#### THE INFLUENCE OF HEREDITY ON DISEASE. (a)

It was a most happy thought of the Council of the Royal Society of Medicine to have instituted a discussion of such breadth and value on this important subject, and it is an equally happy thought to have the discussion published in book form, so that it may be read by those to whom the "Transactions" of the Society are not accessible. The contributors to the discussion contain such distinguished names as Professors Karl Pearson, Bateson, and Sir John McFadyean, and Drs. Mott, Savage, Bullock and Bond. It is impossible here to enter into the individual merits of the numerous questions raised, for they rank among the most abstruse in all science. Heredity is a field where English Science, thanks to the labours of Galton, Pearson, Bateson, and a host of others, ranks at least as high as that of any foreign country, a statement that, unfortunately, cannot be made in many spheres. The present discussion well maintains this eminent level, and furnishes what may legitimately be termed an epoch-making contribution to a subject which is of cardinal importance to the human race as a whole, and to the medical profession in particular. The volume, which is excellently got up, is warmly recommended to all members of the medical profession.

### LITERARY NOTES.

MESSRS. BAILLIÈRE, TINDALL AND COX announce that from July 1st they have taken over the publication of all the books by Sir William Whitla, including "Materia Medica," "Practice of Medicine," and his well-known "Dictionary of Treatment," a new edition of which will be issued in the autumn. They will also in future publish Green's "Pathology and Morbid Anatomy," a tenth edition of which is now in

(a) "The Influence of Heredity on Disease, with Special Reference to Tuberculosis, Cancer, and Diseases of the Nervous System." A Discussion opened by Sir Wm. Church, Sir Wm. Gowers, Arthur Latham, and E. F. Bashford. London: Longmans, Green and Co. Price 4s. 6d. net.

circulation. These changes are the result of the retirement from business of Mr. William Renshaw, head of the old-established firm of Henry Renshaw, which will now cease to exist.

\*\*\*

MESSRS. BAILLIÈRE, TINDALL AND COX also announce the following new works and new editions in active preparation:—Dieulafoy's "Text-Book of Medicine," translated by V. E. Collins, M.D. Lond.; a third edition of the "Manual of Massage," by M. A. Ellison; a second edition of "Practical Microscopy," by F. Shillington Scales, F.R.M.S.; a new edition of "Aids to Analysis of Food and Drugs," by C. G. Moor, F.I.C., and W. Partridge, F.I.C.; a third edition of "Aids to Mathematics of Hygiene," by R. Bruce Ferguson, M.D.; "Sanatorium Treatment of Tuberculosis," by Rufenacht Walters, M.D.; "Surgical Anæsthesia," by Bellamy Gardner, M.R.C.S.; a second edition of "Chemical Notes and Equations," by G. H. Gemmell, F.I.C.; "Gynaecological Therapeutics," by S. J. Aarons, M.D.; "Incidence of Sex and Age on Disease," by J. Grant Andrew, F.F.P.S.; and a second edition of "Menstruation and its Disorders," by Arthur E. Giles, M.D.

\*\*\*

We have received from Messrs. Baillière, Tindall and Cox a pamphlet entitled "The Re-Education and Self-Control in the Treatment of the Morphine Habit," written by Dr. Oscar Jennings. (1s. net.) In this pamphlet the author points out the folly of supposing that all morphinists are hopeless so far as treatment is concerned. Like all neurasthenics they are merely deficient in self-control. Therein lies the key to successful treatment of the morphine habit. Drugs should be used as little as possible. Restoration of will-power should be aimed at. There is much commonsense in the author's teaching, and he deserves a careful hearing. Those of our readers who imagine that morphomania is incurable should procure this pamphlet and inwardly digest its contents. It contains much that is suggestive and encouraging with reference to the therapeutics of this unfortunate habit.

\*\*\*

MR. H. K. LEWIS informs us that he has purchased the remainder of the stock of the New Sydenham Society's publications, comprising the collection of volumes on medicine and surgery, the Pathological Atlas, the Lexicon of Medical Terms, and the Atlas of Clinical Medicine, Surgery, and Pathology, issued by the Society during the years 1859-1907. Many of the works were of a pioneer character when issued by the Society, and have since acquired a classic and historic importance. The number of copies of each book has been of necessity limited on account of the heavy expense of warehousing a larger stock, and of many of the volumes only a small number remained over.

\*\*\*

MESSRS. KNOLL AND CO. have issued a booklet dealing with their preparations in an interesting and scientific manner. The work is quite small, and is entitled "Knoll's Materia Medica," but, as a matter of fact, its scope is much wider than the title implies, for apart from the chemical descriptions of the various preparations, each drug is treated separately and notes on its physiological action, the indications which require it, and the dose and mode of employment are all given. This information is conveyed on the right-hand pages throughout, and on the left pages are clinical notes giving in short, and frequently tabular form, the experience of medical men who have used the drug, as to difficulties, precautions, and so on, to be observed. In all, fourteen different preparations are thus dealt with, and they include digipuration, which is said to be digitalis without unpleasant effect, iodival, an organic preparation of iodine, lenigallol and engallol, both of which have acquired considerable favour, bromural and triferrin. The brochure is a handy thing to have on the consulting-room table, and many fresh suggestions will be found in it especially helpful in treating cases that drag on till all ordinary remedies are exhausted.

## LABORATORY NOTES.

### MOUILLA—A NEW LIQUID SOAP.

MOUILLA is a liquid soap, made with pure potash, and composed largely of high quality oil and glycerine (B.P. 1.260). In appearance it resembles olive oil, and in use one has to pour a drop into the palm of the hand, rubbing as with ordinary soap, when a capital lather is produced. It is also claimed to have the advantage of lathering in the hardest water, of cleansing better than hard soap, of preventing chapping and irritation of the skin, and of rendering the hair silky and glossy. As a toilet soap these are great recommendations, and for the surgeon who is busy with operations and dressings they are godsend. We have tested this *savon de luxe* for ordinary purposes, and can cordially recommend medical men to try it for themselves.

## MEDICAL NEWS IN BRIEF.

### North-East London Post-Graduate College.

THE vacation course of the North-East London Post-Graduate College is to be held this year from September 6th to September 18th at the Prince of Wales's General Hospital, Tottenham, N. There will be continuous arrangements for study during the fortnight from 10 a.m. to 6 p.m. each day, which will comprise demonstration and pathology, on clinical methods, on selected clinical cases, with clinics, clinical lectures and discussions. The fee for the course is two guineas; a syllabus, with further information, may be obtained from the Dean of the School at the Hospital, or at 142 Harley Street, London, W.

### The International Congress of Nurses.

THE meeting of the International Council of Nurses to be held in London at the Church House on July 19th, with the four days of open Congress at Caxton Hall and the Church House on the 20th, 21st, 22nd and 23rd, is expected to be the most remarkable gathering of nurses yet held as to numbers, cosmopolitan character, and distinction of individual members who are coming. Many of the most prominent women in nursing organisation, and who have taken a leading part in advancing the education, training, and special new lines of work for the nurse, are to take part in the proceedings. The subjects to be discussed are varied, and disclose the extent of the demands made upon the trained nurse of to-day, as well as the ever-widening opportunities offered to her.

The officers of the International Council of Nurses are:—Hon. President, Mrs. Bedford Fenwick, London; President, Miss S. B. McGahey, of Australia; Hon. Treasurer, Miss Margaret Breay, London; and Hon. Secretary, Miss L. L. Dock, the United States.

Among the Presidents of National Councils of Nurses are:—Miss Snively, Lady Superintendent of the Toronto General Hospital, Canada; Miss Annie Goodrich, Superintendent of Nurses of Bellevue and Allied Hospitals, New York; Sister Agnes Karll, of Germany; Miss Tilanus, of Holland; Mrs. Henny Tscherning, of Denmark; and the Baroness Mannerheim, of Finland.

At the session on Tuesday, the 20th, the topics discussed will be "Education and Registration," "The Nurse in Private Practice," and "School Nursing"; on Wednesday, "The Nurse as Citizen," dealing with district nursing, social service work, and preventive efforts on various lines, and "The Relations of Nursing and Medicine"; on Thursday, "The Care of the Insane," "Professional Organisation," and "The Nurse as Patriot," covering Army nursing, Naval nursing, etc.; on Friday, "Mission Nursing and Morality in Relation to Health" will be considered. There will be an interesting nursing exhibit of practical appliances, inventions, and devices, books, journals and reports.

### The Mineral Springs of Bath.

LAST week Sir Malcolm Morris, F.R.C.S., was invited by the Corporation of Bath to formally open

a new departure within the beautiful grounds of this historical city. Hitherto, visitors had perforce to drink the mineral waters in the famous Pump Room, but there was no provision made for "taking the waters" in the open during the spring and summer months. To provide pleasant surroundings for the summer cure-guest the Corporation have now erected in the Institution Gardens a handsome colonnade and a fountain, where the hot mineral waters will be served. It would be difficult to find anywhere more beautifully situated grounds. The band plays under the trees in the gardens; gay flower beds and comfortable chairs are everywhere. Near the colonnade is a bit of old masonry—all that is left of the Monk's Mill, once the property of the monks of Bath Abbey when the gardens formed part of the Abbey grounds. The Roman culvert runs underground near by, conveying waste water from the baths, exactly as it did nearly 2,000 years ago.

Drinking the waters in the open air has always been recognised as one of the enjoyable features of Continental spas, which the English health resorts have been slow to adopt. The opening of the fountain and colonnade indicates that not only in the autumn and winter, but also in the spring and summer, is the comfort and enjoyment of visitors considered.

Bath has been bestirring itself in other directions of late. It is to have a "Historical Pageant" during the present month. It has just issued "Bath as a Health Resort," beautifully illustrated in colours, and it is sending its "Sulis" water of known therapeutic value in bottles to all parts of the kingdom. These are encouraging signs that the authorities entrusted with our home health resorts are anxious to compete with the claims of foreign spas, and it affords us pleasure to record the fact.

### Irish Questions in Parliament.

DURING the past week, Mr. Kettle asked the Chief Secretary for Ireland on what grounds Steevens Hospital is selected by the Royal Irish Constabulary for the treatment of constables; whether the hospital enjoys a monopoly among Dublin hospitals for Royal Irish Constabulary patients; what sums per week are deducted from the pay of Constabulary patients and handed over to the hospital authorities; and whether he will explain why two patients suffering from tubercular disease of the lungs, one of whom died, were recently accommodated in the common ward, to the danger of all the other patients.

Mr. Birrell replied that the Constabulary authorities informed him that Steevens' Hospital was selected for treatment of constables on the ground of its proximity to the depôt, and the desirability of having one hospital where special wards could be set apart and kept available for members of the force. It enjoyed a practical monopoly in Dublin for the treatment of Constabulary patients. Single men paid 2s. 3d., married men 1s. 4d., and recruits 1s. 10d. per day for the treatment. One patient who had tubercular disease of the lungs was retained for a time in the common ward on the responsibility of the doctor who was attending him, but was removed before his death.

Mr. Hugh Barrie asked the Chief Secretary whether it is proposed to affiliate the Mater Infirmorum Hospital (Belfast) to the new Belfast University; and, if so, are its teachers and teaching to be recognised; and will the members of its medical staff be admitted upon the Examining Board of the University.

Mr. Birrell: It is not proposed to affiliate the Mater Infirmorum Hospital to the Queen's University. It is proposed by the Medical Faculty that the hospital should be recognised as a place of clinical teaching, as it was by the old Queen's College, but this is subject to the approval of the Senate. The appointment of examiners is for the Senate upon the recommendation of the Academic Council. I have no means of knowing how far the medical staff of this or any other hospital will be recognised by the Senate.

### Guy's Hospital Medical School.

At the annual distribution of prizes to the successful students of Guy's Hospital Medical School, on Friday last, the Dean, Dr. Eason, read his annual report, in the course of which he stated that the entry of students

from October, 1907, to October, 1908, was approximately the same as that of the previous twelve months. The number of students who qualified was also about equal to that of the previous year. From the returns of the General Medical Council, the number of students entering the profession was still much below that of a period of from 10 to 15 years ago. This fact was probably due in some degree to the overcrowding of the profession which resulted from the large entries into the medical schools of London at that time, and also to the increase in the cost of the medical curriculum; but it was interesting to note that this period of depression in the profession seemed to be passing away, and there was no doubt that at the present time the demand for qualified men far exceeded the supply. Applications were being daily received from provincial hospitals unable to get the medical officers they required, and the income that could be made by the recently qualified man was certainly much higher than it was a few years ago. The Dean mentioned that the medical school received no subvention from the hospital funds.

#### **Tribute to Work of Liverpool School of Tropical Medicine.**

THE Liverpool School of Tropical Medicine has received the following letter from the African Association, Limited, viz. :—

"I beg to hand you herewith cheque for £50, being a supplementary grant made to your school by the shareholders of this company, at their meeting of 1st inst., in recognition of the fact that 1908 was the first year in the history of the company in which there had not been a death in the whole of our coast staff."

Colonel Seely, who, as Under-Secretary of State for the Colonies, was notified of the action of the African Association, writes as follows, viz. :—

"Colonel Seely desires me to thank you for your letter enclosing a cutting from the Liverpool paper giving an account of the annual meeting of the African Association. He was glad to see the very practical tribute which was paid by the association to the work of the School of Tropical Medicine."

#### **Irish Medical Schools' and Graduates' Association.**

THE summer general meeting and luncheon will be held at 1.30 p.m. on Wednesday, July 28th, at the Medical Institute, Belfast, the President, Albert Mouillot, Esq., M.D., T.C.D., in the chair. It is hoped as many members as possible will attend. Guests, ladies or gentlemen, may be invited. The charge for luncheon will be 3s. each, to be paid at the time, but in order to make the necessary arrangements and reserve seats, it is desirable to inform Dr. Douglas, Goudhurst, Kent, as soon as possible.

### **PASS LISTS**

#### **University of Glasgow.**

THE following candidates (alphabetically arranged) have satisfied the examiners in the Fourth (Final) Professional Examination for the degrees of Bachelor of Medicine (M.B.) and Bachelor of Surgery (Ch.B.) :

William S. Alexander, M.A., Andrew C. Anderson, William Anderson, James C. Auchencloss, David Barbour, Arthur M. Bayne, George T. Bogle, David Y. Buchanan, Carl J. B. Buchheim, James Cairns, John A. M. Camerson, Andrew H. Clark, Donald J. Clark, James L. Cochrane, Rutherford Cramb, Charles Duguid, M.A., Donald Fisher, Edward J. Fitzgerald, George Fletcher, M.A., Robert Gale, Florence A. Gallagher, Edward G. Glover, Robert D. Goldie, John Granger, Kenneth C. G. Gray, Albert W. Gregorson, Euphemia A. Hay, William A. Hislop, William Howie, Bentley M. Hunter, James T. Kirkland, Alexander Leishman, William T. Lindsay, William M'Adam, M.A., B.Sc., William C. Macartney, William M'Connell, Donald M'Intyre, Robert B. Forbes M'Kail, Campbell Macmillan, John W. M'Nee, John H. M'Nicol, Jeanie D. M'Whirter, M.A., David Manson, Mary C. Mitchell, Hyacinth B. W. Morgan, John M'I. Morgan, Findlay Murchie, Frederic L. Napier, William Niccol, Charles M. Nicol, David Purdie, Jessie D. Rankin, John Robertson, Margaret E. Robertson, Robert C. Robertson, Hugh G. Robinson, Winifred M. Ross, William A. Sewell, B.Sc., James S. Somerville, Rich-

mond Stael, Alexander Stewart, Arthur F. Stewart, Robert W. Sutherland, David C. Suttie, Robert Sweet, Charles H. Wagner, Ethelwyn M. Walters, Hugh White, David M'C. Wilson, Henry J. Windsor David Yellowlees.

The following passed with distinction in the subjects indicated :—

In (a) Surgery and Clinical Surgery, (b) Practice of Medicine and Clinical Medicine, (c) Midwifery. David C. Suttie.

In (a) Surgery and Clinical Surgery, (b) Practice of Medicine and Clinical Medicine.—Robert Gale.

In (a) Surgery and Clinical Surgery, (b) Midwifery.—David Y. Buchanan, Andrew H. Clark.

In (a) Practice of Medicine and Clinical Medicine, (b) Midwifery.—George Fletcher, M.A.

In Surgery and Clinical Surgery.—William Anderson, Charles Duguid, M.A., Robert D. Goldie.

In Practice of Medicine and Clinical Medicine.—Edward G. Glover, Margaret E. Robertson, Winifred M. Ross.

In Midwifery.—James Cairns, William M'Adam, M.A., B.Sc., John W. M'Nee, John H. M'Nicol, Robert W. Sutherland, David Yellowlees.

#### **Conjoint Examinations in Ireland.**

THE following candidates have passed the First Professional Examination of the Royal College of Physicians and the Royal College of Surgeons, July, 1909 :—

M. J. Burns (with Honours), E. Harnett (with Honours), W. I. Adams, P. Ashe, J. C. Blackham, C. C. Boyle, E. Connell, J. D. Cherry, J. Crowley, J. Cohen, P. D. Daly, D. Donohoe, W. St. L. Dowse, T. R. Elliott, D. J. F. Flanagan, B. Goldberg, T. Gray, M. B. Gunn, M. Heenan, E. E. Hobson, F. J. Hunt, A. Humphreys, F. J. Kennedy, M. P. Lee, J. Magner, J. J. Magner, P. M. Moriarty, M. Morrin, B. J. Mullin, K. McGrath, F. T. McKenna, L. McKeever, J. W. O'Brien, T. F. O'Connor, J. P. O'Driscoll, E. B. Palmer, G. E. Pepper, B. Scher, N. A. Sheridan, R. Slaney, E. B. Stoney, J. C. Sproule, J. Stokes, T. S. Sullivan, F. C. Ward.

#### **The Royal University of Ireland.**

THE following candidates have passed the First Examination in Medicine :—

Nathaniel Bestie, Percy L. F. G. Bennett, Denis E. I. Byrke, John D. Carroll, Thomas J. Costello, Michael M. Davitt, Wilfred S. Dixon, William A. L. Dunlop, Edward C. T. Emerson, Thomas Farrell, B.A., Thomas Fennessy, Joseph Garry, William Gault, Stafford Geddes, John G. J. Green, Henry P. Hall, John F. Herbert, Thomas W. G. Hogg, Gerald L. Kennedy, Gordon D. Latimer, James H. Lawlor, Thomas J. Lydon, John B. Lyle, William S. Lynd, B.A., William J. McCracken, William M. H. McCullagh, Sch., William MacDermott, Patrick, McDonnell, James P. McLoughlin, George C. Maguire, Matthew Neilson, Eveline M. Noble, Mary J. O'Connor, Edward J. O'Keefe, Jerome J. O'Sullivan, Edith Robinson, Richard Shanahan, Herbert R. Sinclair, Thomas Walker, Michael J. Walsh, Thomas H. Wilson.

The following Candidates may present themselves for the further examination for Honours in the subjects set after their names. Those qualified in two or more subjects may present themselves for the further examination in all :—

Nathaniel Beattie (Botany, Physics), John D. Carroll (Zoology), Thomas J. Costello (Physics), William Gault (Physics), Stafford Geddes (Botany, Zoology), John G. J. Green (Zoology, Chemistry, Physics), John F. Herbert (Physics), Gerald L. Kennedy (Zoology, Chemistry), Gordon D. Latimer (Physics), John B. Lyle (Botany, Chemistry), William S. Lynd, B.A., (Botany, Physics), William M. H. McCullagh, Sch., (Botany, Physics), Patrick McDonnell (Zoology), George C. Maguire (Zoology), Jerome J. O'Sullivan (Chemistry, Physics), Edith Robinson (Zoology), Richard Shanahan (Chemistry, Physics), Thomas Walker (Botany, Zoology, Chemistry), Michael J. Walsh (Chemistry), Thomas H. Wilson (Botany, Chemistry).

## SUMMARY OF RECENT MEDICAL LITERATURE, ENGLISH AND FOREIGN.

*Specially compiled for THE MEDICAL PRESS AND CIRCULAR.*

**Meat Poisoning Due to Gaertner's Bacillus.**—McWeeney (*British Medical Journal*, May 15th, 1909) reports his observations on an outbreak of meat poisoning which occurred last winter in an industrial school for girls at Limerick. In all there were 73 cases of illness with 9 deaths. The symptoms in the earliest cases came on a few hours after partaking of a certain stew and cold beef, and death in one case occurred after about twelve hours' illness. All the deaths occurred within forty-eight hours. The symptoms, ushered in by severe headache, were those of acute gastro-intestinal irritation, nausea, vomiting and diarrhoea, followed in the more severe cases by profound collapse. Autopsies were made in three cases. From practically all the viscera examined, a typical strain of the bacillus of Gaertner was separated. The blood of those who recovered possessed agglutinins toward it. It was found to be highly pathogenic to rats, mice, rabbits and a calf, but guinea-pigs were immune. The source of the infection of the children was easily traced to a joint of cold beef, which had been served at dinner on the day the outbreak occurred, partly in stew, partly cold with cold bacon. The joint in question had been in the school premises for ten days—five days uncooked, and five days cooked. Part of the same joint was eaten on the third day after its arrival, and part on the fifth, without any ill effect. The beast, from which the beef came, had been killed at least five days before the meat was sent to the school. The beef was, therefore, at least 15 days old, but at the end of the first 10 of those days it was apparently innocuous. McWeeney found that cold beef experimentally inoculated with Gaertner's bacillus rapidly became pervaded throughout, while at the same time the meat showed no obvious alteration either to sight or smell. McWeeney suggests that the animal from which the beef was taken was infected prior to slaughtering, but in view of the fact that the beef was, if at all, very slightly infected five days prior to the outbreak, it seems more likely that it became infected accidentally in the larder during the last few days of its long stay. R.

**Ligation or Excision of Thrombosed Veins in the Treatment of Puerperal Pyæmia.**—Williams (*Amer. Journ. Obst.*, LIX., 5.) The author had five cases, four recovered and one died, a mortality of 20 per cent., which is in marked contrast with the average of 66 per cent. under the expectant treatment of puerperal pyæmia. From his experience he considers the operation valuable, and destined to save many lives if promptly performed. In one of his cases it jugulated the pyæmic process, and in the other three favourable cases appeared to shorten the course of the disease by weeks or months even though they might have recovered spontaneously. The extra-peritoneal method: It is impossible at the present time to express a definite opinion concerning the curative value of this method. The author has not been favourably impressed by the study of reported cases. One of its great disadvantages is the difficulty in determining which vessels are thrombosed, and the consequent necessity of making an incision in both flanks. Moreover, considerable difficulty may be experienced in differentiating the various vessels. On the other hand after laparotomy the vessels are easily differentiated, and the thrombotic process isolated, while the pelvic organs can be examined at the same time. The author considers the only plausible argument in favour of the extra-peritoneal method is the avoidance of peritoneal infection, but this danger is more apparent than real. He believes that the operation should be undertaken whenever a positive diagnosis can be made, while in those cases in which thrombosed vessels cannot be palpated through the vagina the determination to interfere should be

governed entirely by the general condition of the patient, and the abdomen should be opened if she is seriously ill and the clinical symptoms show no signs of improvement, in the absence of peritonitis or broad ligament abscess. All observers agree that the prospects of cure are far greater in the chronic than in the acute forms of pyæmia. As the general consensus of opinion seems to indicate the great superiority of the transperitoneal method, the *technique* of that method alone is considered. If the process is clearly limited to one spermatic, its ligation will complete the essential part of the operation. If there is any suspicion that both spermatics are implicated sutures should be applied on either side. Ligation is usually all that is necessary. If ligation of one or both spermatics is all that is indicated, and the process is not complicated by local inflammation, the prognosis is very favourable, and the patient has a good prospect of rapid and permanent cure. Beskofsky believes that in any event this should be the extent of the operation as if the process necessitates the tying of the hypogastric veins the prospects of cure are minimal and will be reduced by the manipulation. The best possible exposure should be obtained before applying the ligatures. Konatski observed frequent aberrations in the course of the venous trunks of the pelvis. Normally a vein collects blood from the base of the bladder and lower part of the uterus, and unites with another vein from the gluteal and rectal regions to form the hypogastric or internal iliac vein. Konatski has shown that in 30 per cent. the two vessels open separately into the external iliac vein, and so a ligature might easily be applied to the vein from the gluteal region instead of upon that from the uterus. The author gives tables of the reported cases operated upon by the two methods, and has based his paper upon the study of fifty-six cases treated by excision or ligation, fifteen extra-peritoneal, and forty-one trans-peritoneal, giving a mortality of 80 and 43.9 per cent. respectively. F.

**Suppurating Fibroids following Delivery.**—Hall (*Surg. Gyn. and Obst.*, VIII., 6).—Delivery was tedious, assisted with instruments under strict aseptic measures. On the third day, without any preliminary chill, the temperature rose to 104°, with very painful uterine contractions. Vaginal examination showed an irregular mass to the right of the uterus, and firmly in contact with it. The temperature continued high, in spite of salines and douches. The mass slightly increased in size; no fluctuation was found. After a few weeks, the patient still losing ground, it was decided to open directly above the mass. The omentum had become adherent to the uterus and right appendages, completely shutting off the right pelvis. On freeing this, two small interstitial fibroids, discharging pus from sinuses, and a third small fibroid in the cervical muscle, were found. The other organs were normal. The uterus was removed, but death followed from acute sepsis in 36 hours. In conclusion, in puerperal cases in which pus collects, evacuation by the vaginal route is to be preferred. Failing to reach pus from below, opening the abdomen should not be lightly considered; it is better to wait and try again from below. If the septic foci are confined to the uterus, vaginal hysterectomy is the operation of choice. Avoid all unnecessary interference with adhesions in septic cases. Consider them sacred, as Nature's breastworks. F.

THE first meeting of the Court of Governors of the College of Medicine, Newcastle, under its new constitution, was held in the Council Room of the College on July 8th. Sir George Hare Philipson was unanimously elected Chairman, and Ald. W. J. Sanderson, J.P., Vice-Chairman of the Court.

## NOTICES TO CORRESPONDENTS, &c.

**CORRESPONDENTS** requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

### SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, £1s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs 15.12. Messrs. Dawson and Sons are our special agents for Canada.

### ADVERTISEMENTS.

FOR ONE INSERTION:—Whole Page, £5; Half Page, £3 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 28 at £3 3s.; 53 insertions at £3, and pro rata for smaller spaces.

Small announcements of Practices, Assistances, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

**ORIGINAL ARTICLES OR LETTERS** intended for publication should be written on one side of the paper only and must be authenticated with the name and address of the writer, not necessarily for publication but as evidence of identity.

**CONTRIBUTORS** are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland to the Dublin office, in order to save time in reforwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

J. H. M. (Aberdeen).—We have perused the cutting from the journal enclosed in your letter. In answer to your question, we are compelled to say that we hardly think it conducive either to the dignity of the profession concerned, or the status of the individual, to have testimonials published in a lay newspaper in the context for a medical post. Probably the candidate has been the victim of some imprudent friend, or some over-zealous pressman. Such a step could hardly have been taken with his sanction.

PORTSMOUTH.—The references marked in *The Portsmouth Times* are hardly such as recommend themselves to our ideas of the dignity which is supposed to pertain to our profession. Under the guise of a review it becomes what might aptly be described as a "flaming advertisement" of the author. But it is probably occasioned by an over-zealous and injudicious friend. At least we hope so.

Mr. F. H. J.—Communication received as we were "at press." Will be considered in due course.

Q. E. D. (North Wales).—In many cases the sphygmogram has an undoubted clinical value. As a general rule the exigencies of ordinary private practice do not permit of the use of this method of diagnosis. It would be unwise, however, to imagine that graphic methods in head disease have no practical place in the consulting room of the up-to-date country practitioner.

Dr. SAUNDERS.—Thanks for letter and circular—the matter shall be attended to. As to the serum treatment of tetanus, it should certainly be tried, although it must be regretfully admitted that the mortality of the disease has not been hitherto greatly reduced by the introduction of the serum. However, the patient should not be deprived of the additional chance of recovery from a grave condition afforded thereby.

## Meetings of the Societies, Lectures, &c.

### WEDNESDAY, JULY 14TH.

**MEDICAL GRADUATES' COLLEGE AND POLYCLINIC** (22 Chenies Street, W.C.).—4 p.m.: Mr. A. H. Tubby: Clinique (Surgical). 5.15 p.m.: Lecture: Mr. A. Lane: The Surgical Treatment of Constipation.

### THURSDAY, JULY 15TH.

**MEDICAL GRADUATES' COLLEGE AND POLYCLINIC** (22 Chenies Street, W.C.).—4 p.m.: Sir Jonathan Hutchinson: Clinique (Surgical). 5.15 p.m.: Lecture: Dr. J. Collier: Disseminate Sclerosis (illustrated by cases).

### FRIDAY, JULY 16TH.

**SOCIETY OF TROPICAL MEDICINE AND HYGIENE** (11 Chandos Street, Cavendish Square, W.).—8.30 p.m.: Dr. J. P. Maxwell (Amoy): (1) A Case of Amoebic Abscess of the Spleen; (2) A Case of Black-water Fever.—Dr. G. P. Woolley: Preventable Diseases in Siam.—Lieut.-Colonel J. R. Forrest, R.A.M.C.: Fevers in Rangoon.

**MEDICAL GRADUATES' COLLEGE AND POLYCLINIC** (22 Chenies Street, W.C.).—4 p.m.: Mr. G. S. Hett: Clinique (Ear, Nose, and Throat).

**CENTRAL LONDON THROAT AND EAR HOSPITAL** (Gray's Inn Road, W.C.).—3.45 p.m.: Lecture: Dr. W. Wingrave: Clinical Pathology.

## Appointments.

BALL, W. G., F.R.C.S. Eng., L.R.C.P. Lond., Junior Demonstrator of Pathology at St. Bartholomew's Hospital.  
BARRIS, J. D., M.R.C.S., L.R.C.P. Lond., Demonstrator of Midwifery at St. Bartholomew's Hospital.  
DAVIES, H. MORRISTON, M.C. Cantab., F.R.C.S. Eng., Assistant Surgeon to University College Hospital.

ETHERINGTON-SMITH, R. B., M.B., B.C. Cantab., Demonstrator of Anatomy at St. Bartholomew's Hospital.  
FISHER, J. B., M.D., C.M. Edin., D.P.H., Certifying Surgeon under the Factory and Workshop Act for the Whitehaven District of the county of Cumberland.  
GASK, G. E., F.R.C.S. Eng., L.R.C.P. Lond., Demonstrator of Operative Surgery at St. Bartholomew's Hospital.  
HOWELL, C. M. H., M.B., B.Ch. Oxon., Demonstrator of Physiology at St. Bartholomew's Hospital.  
MOORE, R. FORSTER, F.R.C.S. Eng., B.C. Cantab., Demonstrator of Anatomy at St. Bartholomew's Hospital.  
PRITCHARD, HAROLD, M.D., B.S. Lond., Junior Demonstrator of Pathology at St. Bartholomew's Hospital.  
TATHAM, C. J. W., M.R.C.S., L.S.A., D.P.H., Assistant Medical Officer of Health of Scarborough and Medical Officer of Schools.  
WEAVER, A. E., M.D., Ch.B., D.P.H. Birm., Medical Officer of Health of Aberdillery.

## Vacancies.

Birr Union, Frankfort Dispensing District.—Medical Officer. Salary £120 per annum, with Registration and Vaccination Fees. Immediate application to William Lowry, Clerk of Union (see advt.).  
Worcester County and City Asylum, Powick.—Third Assistant Medical Officer. Salary £140 per annum, all found. Applications to the Superintendent.  
Westmoreland Consumption Sanatorium.—Resident Medical Superintendent. Salary £300, with board and residence. Applications to W. B. Parker, M.D., Stricklandgate, Kendal.  
Whitehaven and West Cumberland Infirmary.—Resident House Surgeon. Salary £120 a year, with board and lodging. Applications to W. H. Sands, Secretary.  
Govan Parish School Board.—Principal Medical Officer. Salary £500 per annum. Applications to Mr. M. MacLeod, Clerk to the Board, 151, Bath Street, Glasgow.  
West Riding Asylum, Wadsley, near Sheffield.—Fifth Assistant Medical Officer. Salary £140 per annum, with board, etc. Applications to the Medical Superintendent.  
Wolverhampton Union.—Assistant (Resident Medical Officer), etc. Salary £140 per annum, together with apartments, rations, and washing. Applications to Frank Harrison, Clerk to the Guardians, Poor-law Offices, Wolverhampton.  
Berks County Asylum, Wallingford.—Second Assistant Medical Officer. Salary £150 per annum, with board, furnished apartments, attendance, etc. Applications to Medical Superintendent.  
Birmingham General Dispensary.—Resident Surgeon. Salary £200 per annum, including cab allowance. Applications to Ernest W. Forrest, Secretary, 32, Union Street, Birmingham.

## Births.

BENT.—On July 7th, at Vellum Hurst, Southfields, London, the wife of John Francis Gibbs Bent, M.D., of a son.  
BODINGTON.—On July 10th, at Books Acre, Worthy Road, Winchester, the wife of A. E. Bodington, M.A., M.D., of a son.  
MATHESON.—On July 6th, at "Kintail," Butler Road, Harrow, to F. M. Matheson, M.R.C.S., L.R.C.P., and Mrs. Matheson—a son.  
MILLIGAN.—On July 6th, at 18 Coates Crescent, Edinburgh, to Dr. and Mrs. Harley P. Milligan—a son.  
MOWLL.—On July 4th, at Boreford, Hook Road, Surbiton, the wife of R. Rothwell Mowll, M.D., B.S. Lond., of a daughter.

## Marriages.

GARDINER—TEGETMEIER.—On July 7th, at St. Thomas's, Regent Street, W., B. Hubert J. Gardiner, M.D., of Mount Adon Park, Dulwich, to Ida, daughter of W. B. Tegetmeier, Esq., F.Z.S., etc., of Alexandra Grove, North Finchley.  
HALE—GRUNDY.—On July 6th, at St. John's, Southwick Crescent, London, Robert Eugene Vaughan Hale, younger son of Dr. C. B. D. Hale, of 3 Sussex Place, to Dorothy Agnes, youngest daughter of Lieut.-Colonel F. L. Grundy, late Royal Warwickshire Regt., of 14 Ladbroke Terrace, London.  
MORRALL—MACDONOGH.—On July 7th, at the Church of St. Thomas of Canterbury, St. Leonards-on-Sea, Edgar Percy Basil, only son of Lt.-Colonel A. E. Morrall, of Halidon, Abergavenny, to Rose Ethel, youngest daughter of the late J. MacDonogh, Esq., M.D., of Bridge View, Killarney, Co. Kerry.

## Deaths.

MAYBURY.—On July 4th, at 27 Almeida Street, Islington, Florence Ada, the beloved wife of Horace Mansell Maybury, M.D.

### TO MEDICAL ELECTRICIANS AND MASSEURS.

Unique opportunity of acquiring a Freehold Property and the Goodwill at a moderate price.

**CHELTEMHAM.**—For Sale by order of the Executors, in consequence of the death of the owner, Beech House, a centrally-situated Freehold Residence, with good accommodation and garden, situated on tram route and within three minutes of the G.W.R., and close to the public centres, for many years in the occupation of Mr. G. R. Francis, Medical Electrician, who carried on thereat a highly successful practice. Full particulars from the Sole Agent's, C. H. Bayley and Sons, 4 Promenade, Cheltenham.

# IRISH POOR-LAW AND LUNACY INTELLIGENCE,

Being the Supplement to the "Medical Press and Circular."

WEDNESDAY, JULY 14TH, 1909

**Notice to Correspondents.**

Poor Law Medical Officers and other subscribers to THE MEDICAL PRESS AND CIRCULAR are invited to make use of the facilities provided by the Management of the Journal for obtaining information on all matters connected with the Poor-Law Medical Service or the Medical Profession generally in Ireland.

The Editor will be glad at all times to receive letters or marked copies of newspapers dealing with matters of medical interest. All communications must be addressed to the Office of the Journal, 18 Nassau-street, Dublin, and should be delivered not later than Saturday morning to ensure attention in the issue of the following week.

**EVENTS OF THE WEEK.**

It rarely happens that the *Journal of the Irish Medical Association* contains anything of interest. The numbers for June and July are, however, exceptions. In the former there is a paper, startling in its outspokenness, by Dr. Foley of Ardraheen, on corruption in connection with dispensary appointments. Dr. Foley only states what is known to many but is only mentioned with bated breath, even the price to be paid, two years' purchase, is whispered about. So long as this widespread corruption, was recognised only in gossip, it was possible to ignore it, but now that in its own *Journal*, a sweeping charge has been made, the Irish Medical Association is bound to take the matter up and thoroughly investigate it. It will have to consider whether it will not be forced to alter its policy as regards Dispensaries and the remuneration of medical officers; and withhold its support from efforts to obtain increase of pay where there is any suspicion of corruption.

In the July issue a letter is published from Dr. John D. Crinion, in which, because the ballot for the five elected members of the Committee of Council did not result as he wished,

he raises for the first time in the history of the Association the religious question. This is to be deplored, but what is more deplorable, what is inexcusable, is the publication of the letter in the *Journal*. The Editor is not a new member; he is the Hon. Secretary of the Association; and he knows that Sectarian and Political matters are excluded, and it was plainly his duty to have deleted all references of the sort from Dr. Crinion's letter.

We report in another column the reply given by the Local Government Board with regard to the power of the Castlereagh Guardians to impose the adoption of a scale of fees on candidates for the Ballaghaderreen Dispensary District. A more shuffling declaration that Board never made. It is illegal, says the Board, to make assent to a scale of fees a condition of appointment, but you can ask the candidates whether they will assent, and act accordingly. We reiterate the statement made a few weeks ago, that assent to a scale of fees can be revoked at any time.

The Local Government Board have written to the Ballycastle Guardians stating that the

dispensary medical officers need not be included in the officers' insurance policy under the Workmen's Compensation Act.

Ireland is, after Germany, perhaps the best vaccinated country in the world, and, in consequence, the most free from small-pox. Irish people, though slow to move in health matters, are not by any means adverse to enlightenment, and they have always shown themselves ready to be guided by those with expert knowledge. Fads, therefore, such as anti-vaccination and anti-vivisection, have never prospered in Ireland. It is, then, with some surprise that we learn that an active anti-vaccination campaign is being carried on in the County Wexford. Both in the local newspapers and by public meetings the anti-vacks are making themselves heard. We do not anticipate much success for them in this country.

#### SALARIES IN CASTLEREA.

At the last meeting of the Castlereah Board a Sealed Order was received from the Local Government Board fixing the salaries of Drs. O'Donohue and Donnellan for the reconstructed Dispensary Districts of Castleplunket and Ballinlough. The fixing of these salaries has been a long-standing dispute between the Guardians and the Local Government Board, and on Saturday, the 19th inst., the Guardians passed a resolution of protest against the Local Government Board fixing the salary at the figures stated, and they themselves fixed the salary of Dr. O'Donohue at £112, and Dr. Donnellan at £130, with the result the Local Government Board sent down the Sealed Order with a letter stating:—"The Local Government Board have carefully considered the Guardians' proposal with regard to the salaries of these officers, and they regret that they cannot accept the view that a smaller salary should be fixed for each of the officers concerned than that proposed in the Board's letter of the 20th ult. The increased salary in Dr. O'Donohue's case was fixed in accordance with a scale formulated by the Board when dealing with alterations of Dispensary Districts in connection with the Local Government (Ireland) Act, 1898. This scale was found to work satisfactorily, and was not objected to by Boards of Guardians in any of the numerous cases in which it was applied. The Board have issued an Order under seal (copy of which is enclosed) fixing the salaries at £140 a year in the case of Dr. Donnellan, and £122 a year in the case of Dr. O'Donohue. The issue of the Order will not preclude the Guardians from considering the advisability of suggesting a scale of graded salaries for the various medical officers of the Union, which is a matter the Board have strongly urged upon them on several occasions.

We are glad to see that in this matter the Local Government Board has kept to its point.

#### ELECTIONS.

Dr. Dodd has been elected Medical Officer of the Ballymore-Eustace Dispensary District of the Naas Union at a salary of £125 rising to £150 a year, with £5 as Medical Officer of Health. There was no other candidate. It would be interesting to learn what are the duties expected from the Medical Officer of Health for the sum of £5.

Dr. Coen of Frenchpark has again been elected Medical Officer of the Ballaghaderreen Dispensary District, his previous election having been declared invalid by the Local Government Board, on account of the Guardians compelling candidates to accept a scale of fees.

#### SALARIES IN YOUGHAL UNION.

At a recent meeting of the Youghal Guardians, an increase of £20 in each of their salaries was granted to the medical officers of the Union. The salaries previously paid were respectively £155, £150, £120, £120, to four dispensary medical officers, and £120 to the Workhouse medical officer.

#### CASTLEBAR UNION.

##### "THE NEW GRADE."

The Local Government Board wrote drawing the attention of the Guardians to a suggestion contained in Form L in the half-yearly report of Dr. Hopkins, in which he suggested the advisability of the Guardians adopting a graded scale of salaries for the medical officers in the Union.

Mr. J. P. Canning—It is a great wonder they don't suggest a reduction in the salaries of the doctors.

Mr. T. Canning—The letter is an absurd one.

Clerk—A graded scale has been adopted in a great many unions.

Mr. J. P. Canning—And in a great many unions it has not been adopted.

Mr. T. Canning—Well, it won't be adopted here.

Mr. T. Moran—Dr. Hopkins is getting over £200 a year, and I consider he is well paid.

Mr. Prendergast—But he is doing two men's work.

The communication was marked "read."

#### BALLINA UNION.

Dr. Lang, late Medical Officer of Ballina Dispensary District has been unanimously voted a superannuation allowance of £60 by the Board of Guardians.

The Local Government Board wrote requesting to be informed whether the water supply was now satisfactory.

Mr. Melvin—No, nor never will be.

Mr. Gaughan—There is a committee of both bodies to meet.

The Clerk, in reply to Mr. Quigley, said the committee had not yet met.

#### QUESTION OF A SCALE.

The Castlereah Guardians were specially summoned last week for the appointment of a doctor for Ballaghaderreen Dispensary. About a month ago Dr. J. A. Coen was unanimously appointed on his signing a scale of fees approved by the Guardians. Dr. Beirne, who was also a candidate, but refused to sign the scale, appealed to the Local Government Board, who ordered a re-election on the ground that it was illegal to make the appointment conditional. The Guardians might ask the candidates to sign the scale, but they could not coerce them into doing so. The same candidates were before the Board on Saturday.

Mr. Murphy said they would elect no doctor who did not sign the scale of fees.

Mr. Grogan proposed the appointment of Dr. Coen, who had been for 17 years the doctor for Frenchpark District.

Dr. Beirne said that owing to the absence of his supporters he was reluctantly compelled to withdraw his application, and Dr. Coen was unanimously elected amidst applause.

#### TEMPORARY SERVICES.

Dr. Dolan of Kilnaleck having been summoned to attend at Cavan Quarter Sessions, intimated the same to the Relieving Officer who asked Dr. McQuaid, Ballyjamesduff to do temporary duty. Dr. Dolan being away for two days, Dr. McQuaid sent in an account to the Guardians for £2 2s. od., which they ordered to be paid, resolving at the same time to deduct the amount from Dr. Dolan's salary, as the case upon which the doctor was engaged was not a crown case. Dr.

Dolan wrote a long letter to the Board accusing the Relieving Officer of favouritism inasmuch as he had intimated to that gentleman that Dr. Ryan of Finea, would act if required. He further stated that the appointment made was highly objectionable to him, and he considered the act designedly offensive, and wished to be informed if he could be made to pay for a substitute who was not called in accordance with the Dispensary Regulations.

A letter was, however, read from Dr. McQuaid regretting that the Guardians contemplated deducting the amount of his fee from Dr. Dolan's salary, and stating that inasmuch as he had never taken a fee from a medical man for any professional services rendered, he could not make an exception in this case, and would not, therefore, accept any remuneration. The Board acknowledged their obligation of Dr. McQuaid's action, which they considered both generous and gentlemanlike. A letter was then read from Dr. Dolan, asking for his usual holidays, and nominating Dr. Ryan, Finea, as his substitute. The Board, however, appointed Dr. Clarke, Cavan.

#### WORDS AND WORKS.

As recorded in a recent number of the SUPPLEMENT, Dr. Ross, Medical Officer of the Ballykelly Dispensary District in the Limavady Union, was forced by ill-health and considerations of age, to return after a period of service extending to forty-two years. According to the observations of the Guardians and the encomiums which were showered upon him by the members present at the meeting at which his resignation was received and accepted, no dispensary medical officer ever discharged his duties more faithfully, more efficiently or with more acceptance to the poor amongst whom he laboured. The Guardians felt themselves reluctantly and with sorrow obliged to appoint a successor, and issued advertisements for a duly qualified practitioner at the old salary. Notice of motion was also given to consider on the same day the question of Dr. Ross's superannuation. There was only one candidate for the position, viz., Dr. E. J. Martin of Dungiven, who was, of course, amidst a great flourish of trumpets unanimously elected. In offering his congratulations to Dr. Martin the Chairman informed him "the position he would have to fill was a difficult one, and his money would be hardly earned, indeed doctors always earned their money under great hardships. He was going to succeed Dr. Ross whose devotion to duty was so well known, and universally recognised. Dr. Ross had been fifty years doctor in the Dispensary District of Ballykelly, and his kindness and benevolence would have a lasting effect among the people. Astronomers told them that light from celestial bodies only struck the eye after travelling millions of miles through space and this light continued to exist for hundreds of years after the luminary from which it emanated had ceased to exist. In like manner Dr. Ross by his worth and work had shed a light throughout the community where he laboured which would continue to exercise a beneficial influence long after he himself had passed away. In conclusion he hoped Dr. Martin would uphold the worthy traditions of the dispensary to which he was appointed." Dr. Martin, of course, in reply said he would do his best and the Guardians proceeded to discuss the amount of superannuation allowance they would grant to their late officer. One member proposed and it was duly seconded, that the maximum pension, viz., £87 5s. 8d. a year be granted. It was then moved and as an amendment also seconded, that only £50 a year be granted. The amendment was carried by a majority. Dr. Ross could have resigned on the passing of the Local Government Act and claimed full pension as a matter of right, so that during the past ten years he has been saving the Guardians the salary of a successor. It is such treatment as this that keeps candidates away, and we are greatly surprised that even one could be found to accept the position of dispensary doctor under such a system.

#### THE HEALTH OF DUBLIN.

The annual rate of mortality in Dublin, which had been equal to 15.7 and 19.6 per 1000 in the two preceding weeks, declined again to 18.5 in the week ending July 3rd. During the 13 weeks of last quarter the death-rate in the city averaged 20.9 per 1000, whereas the mean rate during the same period did not exceed 13.5 in London and 15.8 in Edinburgh. The 141 deaths of Dublin residents from all causes registered last week showed a decline of nine from the number in the previous week, and included 13 which were referred to the principal epidemic diseases, against ten and eight in the two preceding weeks. These 13 deaths were equal to an annual rate of 1.7 per 1000, the death-rate from these epidemic diseases being equal to but 0.8 in London, and 0.9 in Edinburgh. Of the 13 deaths from these epidemic diseases in Dublin last week, five resulted from diarrhoea, four from whooping-cough, two from measles, and one each from scarlet fever and diphtheria, but not one either from "fever" or small-pox. The fatal cases of diarrhoea exceeded the number in any recent week, while those of whooping-cough showed a slight decline. The 141 deaths at all ages included 31 of infants under one year of age, and 44 of persons aged upwards of 60 years; the deaths of elderly persons exceeded the numbers in recent weeks. Four inquest cases and two deaths from violence were registered during the week; and 60, or 42.6 per cent., of the deaths occurred in public institutions. All the causes of death registered in the city last week were duly certified either by a registered medical practitioner or by a coroner; in London the causes of all but one of the 1,029 deaths last week were duly certified, and in Edinburgh 2.2 per cent. of the causes of death were uncertified.

#### THE TUBERCULOSIS ACT.

At the Fermanagh County Council a letter was read from the Local Government Board enclosing a memorandum explaining the object of the Tuberculosis Prevention (Ireland) Act, 1908. They trusted that the new powers conferred by the Act for dealing with Tuberculosis would receive the earnest consideration of the Council.

The Secretary said this was a matter of great importance, and it would be better to adjourn the consideration of it till the next meeting, so that copies of the Act might be put into the hand of the members of the County Council.—This was agreed to.

The Navan District Council received a letter from the Local Government Board forwarding a draft of the Tuberculosis Act, and asking the Council to give it their earnest consideration.

Mr. Collins—What do they want us to do?

Clerk—To adopt Section 1 of the Act. If you do so it will make compulsory notification essential, and the doctor can see to the disinfecting of the house in which the consumptive patient is located.

Mr. Owens—If we adopt Part 1 of the Act it will be necessary, and within the power of the doctor to order the patient out of the house—in here or to some other place.

Clerk—I don't know if that compulsion will be resorted to.

Mr. Owens—It may, and I am opposed to Part 1 of the Act.

Mr. Collins—I propose that we do not adopt Part 1 or any Part of the Act. By adopting it we would be inflicting a great hardship upon people who have sick relatives suffering from some disease which might be supposed to be consumption.

Mr. Steen—Not "supposed," but patients really suffering from consumption.

Mr. Collins—I say "supposed," because I have seen cases where doctors have differed. I think the medical profession are trying to reap some pecuniary advantage by this scare which has been raised in Ireland by people

who are working with the best of intentions. If we enforce it people will be obliged to notify the sanitary authority that one of the family is suffering from consumption. Now a great many will object to that as an intrusion on the privileges of family life, and it should not be tolerated. He was sure that the family in which one of the members might happen to be affected with consumption would be as much concerned for the welfare of the poor patient, and would be willing and anxious to do whatever they could either by isolation or otherwise, as the sanitary authority would be.

Mr. Dwyer agreed with Mr. Collins, and seconded the resolution.

Mr. Steen said the doctors were anxious for compulsory notification, and perhaps in some cases if they thought fit, it might be advisable to have steps taken for the isolation. This (consumption) was a terrible speck on Ireland, and we who are not experts in the matter should do nothing to prevent these people from using the best means in their power to prevent the

spread of the disease. These medical men are instructed in this matter, and we should certainly be guided by them.

Mr. Owens said perhaps the matter might be postponed for further consideration.

Mr. Steen—We have never objected to the notification of measles or scarlatina. It is now well known that Tuberculosis is contagious.

Mr. Collins, replying to Mr. Owens, said he hadn't proposed the resolution without some consideration, and he had also interviewed people who knew more than he did, and if they did adopt Section 1 of the Act such people suffering from consumption must be isolated, and you have no place to isolate.

Mr. Owens—Be satisfied, Mr. Collins, by proposing a resolution to the effect that for the present we deem it inexpedient to adopt part one of the Act, and if we see fit we can do so afterwards.

Mr. Collins fell in with that suggestion, and the matter dropped.

**THE DUBLIN INSTITUTE OF BACTERIOLOGICAL AND CLINICAL RESEARCH,  
LABORATORIES—21 LOWER ORMOND QUAY, DUBLIN,**

Are now Open to receive all species of material for Clinical and Bacteriological investigation.

All investigations carried out under the personal supervision of the Director. Prospectus and Scale of Charges on application to the Secretary.

Telephone—No. 1831, Dublin.

Telegraph—Bacillus, Dublin.

Director—**Mr. C. JOCELYN O'HEHIR,**  
Late Bacteriologist to the City Laboratories, Dublin.

**HIGH-CLASS STATIONERY,

# THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX."

VOL. CXXXIX.

WEDNESDAY, JULY 21, 1909.

No. 3.

## NOTES AND COMMENTS.

ONE of the distinguishing features of the proprietor of nostrums is the *Nostrum* fathomless, if perverted, ingenuity. Foiled in one quarter, he learns from experience, and thrusts out his tentacles more warily in waters lying outside the meshes of the law. One of the most recent devices is to insert a query from a correspondent describing some ailment, and asking if any readers of the journal who have had experiences in a similar direction can tell of any means of alleviating or curing this "awful" complaint. In the ensuing number, sure enough, comes the answer, probably dated from one of the oldest and most exclusive clubs in London. The writer recognises the disease from bare description, although a skilled medical specialist would probably require a careful and detailed examination before forming an opinion upon the case, and, having named the disease, what is easier than to name a remedy? In order that the whole world may share the benefit of the suggestion, the Editor does not limit the information to the original correspondent, but publishes in full the address, name and price of remedy, and its London agents. Further comment is needless, but it certainly looks as if patent medicine advertising were being more or less raised to the level of a high art.

### Medicine— Law.

THE annual dinner of the Medico-Legal Society, last week, helped to bring to general notice the desirability of medical men and lawyers meeting on common ground. The Society has been in existence for eight years, and the rapidly-increasing membership—no less than fifty new members joined last year—shows that it supplies what is called in current journalistic jargon a "felt want." The need for some means of bringing the two professions into contact, so that their agreements and disagreements may be realised, is of great importance, for the more that the good lawyer and the public-spirited medical man are associated, the more evident it becomes that, though they approach problems from different points of view, their ideal is the same. *Salus populi suprema lex*—the motto adopted by THE MEDICAL PRESS AND CIRCULAR more than seventy years ago—is the goal of each, but while the medical man, naturally, translates *salus* to himself as "health," the lawyer interprets it to mean, what Cicero originally intended it to mean, "security." Now, civil security, used in a narrow sense, may be understood to convey nothing beyond the rights of an ordinary citizen, but, in the light of modern ideas, it embraces not only safety from enemies, public and private, but that reasonable security from disease-producing conditions which we now consider as a right of citizenship.

IT is a fault no less of lawyers than of medical men that, with this common aim in view, they are inclined habitually to lay undue stress on that means of promoting it which lies—in their view—the most readily to hand. The lawyer sees his way through statistics and proved facts, and—if we may say so without undue conceit—the medical men sees his through common-sense founded on personal observation. Lawyers cannot, in the exercise of their profession, know facts at first hand, whereas medical practice leads directly to them. Herein lies the great gulf which separates the callings, the lawyer calling for proof and the doctor for action, each being apt to regard the other with a certain amount of impatience for not knowing or seeing things from his own point of view. Now, the Medico-Legal Society, composed as it is of doctors, lawyers and laymen interested in medico-legal matters, helps greatly to bring about a common understanding, and by creating an arena in which difficulties may be brought to issue. For such a Society we conceive there is a large field of usefulness. The Master of the Rolls, speaking at the dinner, dwelt particularly on the part which medical men play in the law courts, and he made the striking observation that medical men do not give evidence in court, in the usually accepted sense of the term, but that they give information to the court, information without which the court would be at a loss to know how to act. Moreover, he made play—and good play, too—of the old cant phrase about doctors differing. He could not conceive, he said, how men of different minds, confronted with grave and perplexing problems, could possibly always arrive at the same conclusion, for even in law it was his own duty every day to sit to revise the judgments of his colleagues, and his court in turn was subject to the still-further-considered opinion of the House of Lords. We have read nothing more encouraging of late than these words of Sir H. Cozens-Hardy, for it shows that in the morass of difficulties in which the profession is struggling the highly-placed members of the judiciary understand and appreciate their position, and that, unlike some of the lesser lights, they are averse from the cheap sneer which rises easily to the lips of those unversed and untrained in the real problems of social existence.

### Medical Training.

ONE of the greatest of the problems confronting the profession is that the training necessary for qualification is yearly becoming more and more exacting, and whereas twenty years ago a lad of eighteen with a decent school education could become qualified in four years without displaying any astonishing feat of mental gymnastics,

to-day, not only is five years the minimum, but fewer and fewer men take an ordinary qualification under seven years. After that follows—or certainly should follow—three or four years of work in subordinate, but responsible hospital posts, before a man enters on his life's work. Now, not only is this state of things a source of great expense and anxiety to the would-be doctor and his relatives, but medical men are finding that with the increased pressure to procure good professional training, the rewards of good work are becoming fewer and less enticing. Moreover, the medical man is regarded as a doctor, and nothing else, and he finds himself, in practically every department of life, the servant of those who have come through far less exacting ordeals than himself, and are consequently of a much lower grade of mental training and discipline. How galling this is to medical men we have examples every day in coroners' courts, the Army and Navy, and all public services in which the medical man is called upon to play a necessary, but subordinate part.

**Its Recognition—** A FURTHER example—if any be needed, is revealed in the just-published report of the Departmental Committee of the Colonial Office, which was appointed to inquire into the conditions of the West African Medical Department. The medical officers, even under the improved conditions instituted by Mr. Chamberlain, in the West African Colonies have many real grievances, and the Committee's report has been almost entirely in favour of the claims made for redress, though we need hardly say the reforms have been to a large extent rejected by the Colonial Office. All those changes which the Office thinks will save them trouble and give them a good supply of medical officers have, it seems, been adopted, whilst all those which would increase the dignity and usefulness of the members of the medical staff have been repudiated. Reading between the lines of the report, it is not difficult to see the old trouble with which the profession is faced has been encountered again in West Africa, namely, that the medical man is not allowed by the civil officials to be "boss of his own show." The class of man from which the Civil Service of the West African Colonies is recruited is notoriously greatly improved, and the Colonial Office now have at their command the services of a supply of fairly average men who, though they cannot obtain appointments in the better and healthier services, are a great improvement on the old ne'er-do-wells who used to man the staff. But, even so, it is anomalous, to say the least, that these gentlemen, whose education and mental endowments are of limited extent, should be set to "administer" medical men of far longer training and higher qualifications than themselves, and we find, as is not unnatural, that the doctors resent their drug bills being cut down and their duties fixed for them by officials of a very moderate order of capacity.

**And "Reward."** FURTHER still, the opportunities for a doctor to pass into the Civil Service and become an administrator are practically *nil*. His rewards are confined to his own branch of the service, and whereas an industrious district commissioner may reasonably look forward to becoming a Colonial Secretary or Governor, with a K.C.M.G. and considerable social precedence, the opportunities of a doctor are limited and restricted in the highest grades to becoming principal medical officer of a colony, with a doubtful C.M.G., half a

governor's salary, and no prestige. If medical services are graded on this basis, it is surely obvious that they will soon cease to attract the best men, who will naturally be put by parents who consider future conditions into the civil branch, and that if the lower type of man alone is attracted, not only will the health and lives of officials suffer, but, by ill-directed advice, the whole civilisation of the unhealthy Colonies will be hung up for generations. There is nothing more phenomenal, and nothing more creditable to medicine, than the immense improvement which has taken place in the health of Europeans on the "West Coast" in the last twenty years, and surely officialdom must be blind in the extreme if it refuses to recognise facts which are the common-places of the unofficial world.

## LEADING ARTICLES.

### THE FERMENT TREATMENT OF DISEASE.

WE regret to see that our contemporary, the *Times*, has been misled into making an assertion which appears to us unjustifiably premature, and therefore opposed to the true interests of science. The following quotation from a leading article on "Cancer Research," which appeared on July 10th, will explain the matter to which we allude:—"A year or two ago great praise as a remedy against cancer was bestowed upon a substance called trypsin, derived from the pancreatic secretion, and while Dr. Bashford himself does not condescend to notice it, we are informed by the executive committee that facilities for further experimentation by an entirely independent investigator on the means of checking the growth of malignant tumours by the injection of trypsin and other like preparations were afforded in their laboratories, and gave entirely negative results." This statement, we submit, is not justified by the facts, nor is it in accord with the spirit which animates all true scientific research, to condemn contemptuously a particular investigation or inquiry merely because a limited series of observations, occupying a few months, have yielded negative results. The subject in question is so exceedingly complex that quite possibly some years will elapse before any definite results can be obtained. Meanwhile the Imperial Cancer Research Fund have informed the public, through the *Times*, that nothing can be expected of any inquiry of the kind. Clearly, in assuming so arrogant a position, the authorities of the Fund have constituted themselves the arbiters of an inquiry, concerning the results of which no one can make an approximate forecast. It may, however, be of some interest to recount briefly the connection of trypsin with the cancer question. In 1905, Dr. Shaw-Mackenzie conceived the idea, based upon various investigations, of submitting to trial the hypodermic administration of trypsin in cases of inoperable malignant disease. Soon afterwards a sample of the preparation he used was forwarded by request to Edinburgh, with which a small series of mice with Jensen's tumours were injected. In one case the cancerous tumour gradually began to disappear, and, after the animal had been killed and the growth examined microscopically, it was found that the cancer cells were clearly undergoing disintegration. It was concluded at once that this disintegration of the tumour was due to the action

of the trypsin injection. Then was the doom of trypsin in the treatment of cancer sealed. From that time onwards the press of this country and abroad blazoned forth the immature results. There was no stemming the erroneous impressions, the false hopes, the cruel disappointments, excited by exaggerated statements, unsupported by scientific testimony, thus made public. Even one writer, in a flamboyant effusion, arrogantly assumed the rôle of a prophet, and in the columns of an evening journal hysterically waved a flag—metaphorically—upon which was inscribed in the largest letters, "The Conquest of Cancer." Furthermore, the same writer pursued his campaign by contributing a series of articles to a morning journal, in which the same prominence was given to similar preposterous statements. From that time the scientific interest in the action of trypsin in relation to cancer died, under a stigma of well-merited reprobation. Whatever its virtues, whatever its deficiencies, whatever its possibilities, despite the fact that at birth it was a normal offspring of scientific conception, there was no room for it in the world of science. It became, at once, from the point of view of science, a monstrosity, an object of universal abhorrence, totally unworthy either of concern or attention, and, still more, of scientific inquiry. With this not altogether surprising result Dr. Shaw-Mackenzie had nothing whatever to do. The public, nevertheless, had been informed by the press that this great discovery, claimed as having been made in Edinburgh, was being practised, with marvellous success, in almost every country in the world, save England. It is needless, however, to pursue further the recital of how the trypsin treatment of cancer came into being, and how it fared. Suffice it to say that the scientific feeling against it still persists, and yet the *furor* regarding the irresponsible allegations of its value having now been permitted to expire, the time seems to have come when the subject should be viewed from a purely scientific, judicial aspect, and especially so when the great problems are remembered which its introduction has initiated as the basis of scientific investigation. While the truth cannot be controverted that certain sufferers have derived considerable relief from the administration of trypsin in cancer, this fact is, nevertheless, of but little scientific import in itself; on the other hand, it undeniably affords valuable encouragement in the prosecution of the highly elaborate and exceedingly complex investigations into the ferment treatment which the use of trypsin has suggested. Moreover, these investigations are now being assiduously carried out by Dr. Shaw-Mackenzie in the laboratories of King's College Hospital, over which Professor Halliburton presides. It is true that Dr. Shaw-Mackenzie's investigations in the Cancer Research laboratory into the action and inter-action of several ferments, including trypsin, upon Jensen's tumours in mice, were negative as a whole. But clearly it is neither just nor generous to him to condemn *in toto* the researches which he carried out, constituting as they did a mere fragmentary beginning of a great inquiry. As he himself has said, while recording his results in the *Lancet*, "it is too early to conclude that these results are condemnatory of the whole theory of intra-cellular fermentation and ferment treatment in carcinoma. They refer solely

to the hypodermic method of administration or to particular combinations of the extracts employed." And who is there who could find fault with this plain statement of fact, having regard to the issues which are now involved? Indeed, the same argument, advanced by the Cancer Research Fund against the results obtained by Dr. Shaw-Mackenzie, might equally be advanced against the authorities themselves. The Fund has now been seven years in existence; it was founded for the express purpose of throwing light upon the ætiology of cancer. But, with every wish to be fair in our criticism, it is impossible to say more than that the Fund is still merely feeling its way in the elucidation of the problems presented to it. But while, however, the authorities of the Fund are apparently glad enough to shelter their operations behind the plea of the natural inability to show immediate results, they at the same time should not lose sight of the fact that fellow-workers in the same field of inquiry are equally entitled to similar consideration.

## CURRENT TOPICS.

### The L.C.O. and X-Rays.

It may seem hardly worth mentioning in a medical journal that the X-ray treatment of ringworm has been practised for some six years now with great success, but the fact is important from the point of view of the silly attitude adopted by a certain class of journal, which sees in any fresh discovery of medicine a damper to its own prestige. This "prestige" is created by liberal abuse of medical men who have fallen into error, and such journal finds that it pays with its readers to dwell with a vindictive and ghoulish delight on the mistakes, honestly committed, by professional men charged with a heavy responsibility, and guided by a science struggling to find its way out of a slough of superstition and unsound tradition. The treatment of ringworm was an opprobrium of medicine till the discovery of X-rays, and the application of the X-rays has not only revolutionised that treatment, but it rendered unnecessary the provision of special Poor-law schools for the segregation of infected children—a boon not only to the ratepayer, but incidentally to the cause of humanity, which rightly regarded the "barrack-school" with abhorrence. Some faddist of the "anti" type, however, started the cry that the use of X-rays stunted the development of the brains of the children on which they were used, and the cry was re-echoed by journals of the class we have mentioned. It is instructive to read, therefore, that the London County Council Special Schools Sub-Committee reported last week, in connection with the brilliant results attained by the treatment:—"We may add that it has been brought to our notice that a quite unjustifiable scare was raised recently as to a possible danger to the brain from the use of X-rays, and that there has been no case of damage or injury of any kind to the children treated in the school." We hope this fact will be duly noted in the quarters indicated.

### Declining Birth-rate in Liverpool.

A good deal of interest attaches to the Liverpool birth-rate, representing as it does a large town with a mixed population. For the last thirty years it has showed the general decline which has prevailed not only in other parts of the United King-

dom, but also in the Colonies and on the Continent. In the year 1848, the rate, with 541,031 population and 20,071 births, was 37.1 per 1,000. From that time there has been an almost regular downward curve, until, in the year 1908, with a population of 753,203, and total births to the number of 23,891, we find a birth-rate of 31.7 per 1,000. In spite of the prolonged decrease of births, there has been a steady increase of total population, the natural increase of which is, therefore, not seriously affected. Although the decrease in Liverpool is marked, it is by no means so great as in other parts of the country, and among the great towns having a population of over 100,000, Liverpool stands fourth highest as regards birth-rate. The net increase of births over deaths for the year 1908 was 9,961, and in only one district in the centre of the city was there any actual decrease caused by the excess of deaths over births. The extremely variable conditions of the various districts of the city may be gathered from the fact that in two the death-rate was 28.9 and 28.8 per 1,000, and in the lowest 12.0, 12.1 and 9. On the whole, the total city death-rate of 18.5 per 1,000 may be regarded as highly creditable to the local authorities.

#### **The Tuberculosis Prevention Act in Ireland.**

We have received from the Local Government Board for Ireland copies of the various orders issued under the Tuberculosis Prevention Act, together with an explanatory memorandum on the objects of the Act. We have already commented on certain unsatisfactory features in the Act, which will render its operation somewhat nugatory. It is to be hoped that the activity that is to take place will not be such as to rouse the hostility of the medical profession. Certain clauses of the memorandum, however, raise a suspicion that the attention paid to medical interests by the Local Government Board is not satisfactory. In particular, the suggestions as to the lines on which dispensary systems for tuberculosis are to be run appear altogether to neglect the rights of the private practitioner. We learn that the dispensary "is in reality much more than a mere out-patient department of a hospital; it is rather an educational dépôt or clearing-house through which nearly all the cases of tuberculosis in a district are passed. . . . Its functions are to attend to all cases of tuberculosis in the area it serves. Some of its cases it drafts into a sanatorium, others it places in hospitals, the remainder it looks after in its own homes through the services of the medical officer and a staff of nurses or health visitors." As far as we can judge from this language, it is the intention of the Local Government Board to deprive sufferers from tuberculosis of the care of physicians of their own selection, and drive or bribe them to the "dispensary." The entire treatment of tuberculosis is to be taken out of the hands of the profession generally, and given to the officials, medical officers, nurses, and health visitors of the "dispensary." This is not a plan likely to commend itself to the good opinions either of the medical profession or of the community at large.

#### **The Newspaper Press and Quackery.**

We publish to-day a letter from Mr. Henry Sewill on the above subject. It is couched in strong terms which we are bound to say are fully justified. It is impossible that editors, managers and proprietors of newspapers can be ignorant of the character of quackery, and especially the traffic in nostrums and bogus apparatus. The whole system has been elaborately exposed during late years by the medical papers, especially by ourselves. Analyses of great numbers of every class of "patent" medicine, showing their worthlessness for their purpose, as well as their insignificant money value, have been made by the British Medical Association, and published in the *Journal*. The Report of the Australian Royal Commission, which was noticed in at least some leading British newspapers, was also alone enough to fully lay bare the facts, whilst cases in the law courts of every grade have again furnished evidence enough to open the eyes of men much less astute than the directors of great newspapers. Some papers which formerly rejected quack advertisements, and took occasion to expose and denounce quackery, now admit the worst class of puffs. It is amazing to see that the proprietors of some of these papers allow their editors still to attack and lay bare a system of fraud from which they themselves are drawing great incomes. Fraudulent medical quackery forms one of the greater of the smaller—albeit sufficiently big—evils which at present afflict society. The injury falls in by far the greater part on the poor and ignorant classes. It is impossible to believe that it will for long remain ignored by statesmen capable of bringing the question before Parliament, and finding a remedy for at least the more glaring of the abuses of which we now complain.

#### **Hospital Abuse.**

THE recent Report of the Leith Hospital directors records a "growing conviction" that the dispensary branch of their organisation was abused by persons able to pay for medicines. The Committee felt loth to take the drastic step of closing the dispensary, but, short of that, they recommended a more stringent method of ascertaining whether the cases were really necessitous or not. They thought it quite possible to frame such a series of questions as would show the facts of the applicant's position. The Managers suggested that it would be sufficient to take, say, every fifth or every tenth case for inquiry. This recognition of a scandalous situation, it may be hoped, stands as a sign of the times. The self-criticism that marks the present age must infallibly extend one day to its charitable methods. Economically, the system of promiscuous alms that bestows gratis medical relief upon those who are able to pay for professional aid stands self-condemned. It is to be hoped that the citizens of Leith, having recognised the evil, will not be slow in applying the remedy. Why should not any person who fills up a form wrongfully be prosecuted for obtaining money, or its equivalent, under false pretences? The Leith hospital authorities have clearly defined the class that they wish to relieve by means of their dispensary, namely, persons not so poor as to be paupers, and not so well off as to be able to provide themselves with medicines and any little attendance when ill.

## PERSONAL.

THE PRINCE OF WALES, as Grand Prior of the Order of St. John of Jerusalem, at Marlborough House, on July 9th, presented the awards of the Order granted during the past year for saving life, and the Service Medals awarded for conspicuous services.

THE DUCHESS OF ALBANY presided at a meeting of the Executive Committee of the Jubilee Fund of the National Hospital for the Paralysed and Epileptic, Queen Square, on July 8th, for the purpose of making arrangements for the visit of the Princess of Wales on Saturday, October 9th, on which occasion Her Royal Highness will receive purses of £10 and upwards.

DR. J. W. EAKIN, District Medical Officer, Port of Spain East, Trinidad, is acting as Surgeon-General of that Colony during the absence on leave of Dr. H. L. Clare.

DR. H. BROWNE, Frankford, has sent in his resignation to the Birr Board of Guardians, having served in the position of Dispensary Medical Officer of the Frankford District for a period of nearly 50 years.

ON Saturday, July 10th, which was Degree Day at the University of Liverpool, Lord Derby, the Chancellor, conferred the honorary degree of M.Ch. on Mr. Robert Jones and Mr. William Thelwall Thomas.

THE late Dr. Percy Boulton, M.D., Consulting Physician to the Samaritan Hospital for Women and Children and to the British Home for Incurables, left estate valued at £20,500 gross. He bequeathed £100 to the Samaritan Hospital.

At the first meeting of the Council of the University of Bristol, on July 9th, Dr. Lloyd Morgan tendered his resignation of the office of Vice-Chancellor, and Sir Isambard Owen, M.D., Principal of Armstrong College, Newcastle-on-Tyne, was elected in his stead.

THE eighth International Congress of Tuberculosis was opened at Stockholm on July 8th in the Chamber of the Upper House of the Riksdag. M. Bourgeois, of Paris, presided, and the company included Prince Carl, Princess Ingeborg, and Prince Eugène, and there were also present delegates and representative scientists of all nations.

DR. E. T. BORN has resigned the office of Colonial Surgeon of the Falkland Islands. He entered the Colonial Civil Service as Assistant Colonial Surgeon of St. Lucia in 1901, and was transferred to the Falkland Islands two years later. He is to be succeeded by Dr. R. S. Earl, Commissioner and Medical Officer of the Virgin Islands.

THE Leyton Urban District Ratepayers' Association have affixed a memorial tablet to the birthplace of Sir Morell Mackenzie, 742 High Road, Leytonstone. The premises are near the tram terminus, and within five minutes of Leytonstone G.E. Railway station. The tablet was unveiled on Monday last.

ON Monday evening, July 12th, in the board room of the London Temperance Hospital, under the presidency of Alderman Sir T. Vezey Strong, Chairman of the Board of Management, a portrait of Dr. Dawson Burns was formally presented to the hospital. Dr. Burns was Hon. Secretary of the Provisional Committee in 1871-73, and has been the Hon. Secretary of the institution from 1873 to the present time.

THE Committee of the Royal National Orthopaedic Hospital (with which is incorporated the City Orthopaedic Hospital), announces that His Majesty the King has consented formally to open, at 12 o'clock on Friday, July 23rd, the new hospital which has just been completed in Great Portland Street.

MR. R. E. MONTGOMERY, formerly Professor of the Liverpool University, has been appointed to the post of Veterinary Bacteriologist of the East African Protectorate. For the past two years Mr. Montgomery has been attached to the sleeping sickness expedition of the Liverpool School of Tropical Medicine in association with Dr. Allan Kinghorn, and has made a special study of tropical diseases of animals.

THE third Norman Kerr Lecture of the Society for the Study of Inebriety was delivered by Professor Taav. Laitinen, M.D., Professor of Hygiene and Director of the Hygienic Institute in the University of Helsingfors, Finland, yesterday, in the lecture theatre of the Victoria and Albert Museum, South Kensington. The subject of the lecture was "The Influence of Alcohol on Immunity."

At a meeting of the West India Committee it was decided, on the suggestion of Mr. Owen Philipps, M.P., to send the following telegram to Mr. Chamberlain: "Mindful of all you have done for the West Indies and the Colonies, and the interest you take in the School for Tropical Medicine, the members of the West India Committee desire to express cordial greetings to you on the occasion of your birthday."

THE body of the late Dr. Cowas Lalca, M.D. Brux., J.R.C.P. Lond., L.M.S. Bombay, who was shot while endeavouring to protect Sir Curzon Wyllie, has been buried in Brookwood Cemetery. There was a large attendance of prominent Indian residents in London, and Viscount Morley, Secretary of State for India, was represented. The coffin bore the inscription "Dr. Cowas Lalca, of Shanghai and Bombay, died July 1st, 1909, aged 48 years," and was accompanied by many beautiful wreaths, including one from Lady Wyllie.

At the Festival Dinner held in aid of the funds of the Charing Cross Hospital at the Whitehall Rooms on July 13th, under the presidency of the Lord Mayor of London, it was announced that £2,613 had been received. In responding to the toast of "Success to the Hospital," proposed by the Lord Mayor, Viscount Ridley, the Chairman of the hospital, appealed to the generous public for help in reducing the outstanding mortgage of £85,000, interest and sinking fund charges upon which are a severe handicap to the committee.

SIR HECTOR CLARE CAMERON, on behalf of the committee of subscribers to the fund in memory of the late Dr. James Finlayson, of Glasgow, has presented a deed of gift to the Council of the Faculty of Physicians and Surgeons of Glasgow, conveying to the council the future management of the fund. The income from the fund is to be held and applied as the endowment of a Lectureship to be called "The Finlayson Memorial Lectureship." The first lecture under the management of the original committee was given in February, 1908, by Dr. Norman Moore, of London, who lectured on "The Schola Salernitana; its history and the date of its introduction into the British Isles."

THE villagers of Lipka, in the Schlesselburg district of Russia, have assaulted the disinfecting staff in a cholera-infected cottage, and destroyed their apparatus. A force of police has been sent to the scene of the disturbance. Some days ago the peasants in the Tsarskoe Selo district demolished the cholera hospital. The number of cholera cases in St. Petersburg alone is now between 700 and 800.

# A CLINICAL LECTURE

## ON

### INFANTILE SCURVY. (a)

By T. D. LISTER, M.D.Lond., F.R.C.S.Eng.,

Physician to Out-Patients, Royal Waterloo Hospital for Children, and Physician to the Mount Vernon Hospital for Consumption and Diseases of the Chest.

THE growing practice in the retail milk trade of regularly pasteurising all milk before it is delivered to the consumer has suggested to me the desirability of recapitulating some of the clinical points in the ætiology and diagnosis, and in the preventive and curative treatment of infantile scurvy. I do not propose to describe the morbid anatomy.

I need scarcely remind you that this disease is known everywhere on the Continent of Europe as "Barlow's disease." The first clear description of the condition was given by Sir Thomas Barlow in 1883. The disease had not been previously differentiated, although the credit of first describing it must be given to Møller, of Königsberg, in 1859, who described the cases under the name of "acute rickets." The first recognition of the real nature of the malady was in 1873 by Jalland, in London, and Ingersley, in Denmark. Their description was confirmed in 1879 by Cheadle, who regarded the cases as scurvy occurring in the course of rickets, his classical paper leading to the wide use of the term, "scurvy rickets." Sir Thomas Barlow adopted the view that the condition was one of scurvy, but showed that rickets was an independent condition, and might, or might not, be present with the essential changes which constitute the disease.

It occurs especially in the months of first dentition. As Dr. Still has pointed out, from an analysis of sixty-four cases under his own observation—a very exceptional experience—nearly 80 per cent. of the cases occur between the ages of six and ten months. Age is, therefore, an important point in the diagnosis.

The disease, as it presents itself clinically, is chiefly characterised by tenderness of the limbs, with swellings upon the shafts of the long bones.

Such a condition occurring in a child in the second six months of life should lead at once to an investigation into its diet. As Dr. Cheadle has suggested, limb tenderness alone sometimes justifies the diagnosis in children of this age.

Symptoms of secondary importance are such as occur in scurvy generally, and are very variable. They are hæmorrhage from, or purple discoloration of, the gums, cutaneous hæmorrhage, purpura and petechiæ, and bleeding from the nose, stomach, bowels or kidneys. Such bleedings occur in less than half the cases.

The remaining symptoms are fever, usually of moderate degree, and not always present, but, as a rule, associated with the degree of subperiosteal hæmorrhage existing, and certain special conditions dependent also upon these hæmorrhages, such as, for instance, exophthalmos, from orbital subperiosteal bleeding, this exophthalmos being of sudden onset, usually unilateral, and sometimes developing during a fit of crying; depression of the sternum as though driven backward *en bloc* (as described by Sir T. Barlow), due to separation of the costo-chondral joint; or soft crepitus from separation at or near an epiphysial line.

The child is usually flabby, always more or less

anæmic, is not necessarily wasted, and evidence of rickets is often entirely wanting, though most cases present it, as might be expected, the disease being one of faulty nutrition.

The lower limbs are much more frequently involved than the arms, nearly ten times as often, and it is quite uncommon for the arms to be affected alone, the appearance of swelling in the legs generally preceding that in the arms.

Here is a brief history of a case that has recently come before me. I give it to you from the medical attendant's own notes, which he kindly furnished to me:—

*Case 1.*—On February 9th, this year, a baby boy, æt. 9 months, was brought to see a doctor in a north-east suburb. The father stated that he feared he had injured the child's left leg in lifting him out of the perambulator, because the child cried whenever the leg was moved, and did not move it voluntarily. On examination, the doctor could find no evidence of injury, but the left leg was painful either on active or passive movement. A week later the right leg became affected. During the next fortnight the child got gradually worse, the pain increasing so that the slightest movement caused intense suffering, the other parts of the lower limbs becoming involved, so that he lost all voluntary movement, and screamed if raised in such a position that the legs hung down. At this time the doctor found that the legs below the knees were swollen. The temperature was found to be 100° F. on two occasions. There was sweating about the head and shoulders. The child seemed to waste, and the motions were found to be green and foul-smelling. There was no vomiting. The diagnosis made was epiphysitis, and a doubt was raised as to the possibility of there being spinal meningitis. A neighbouring practitioner who saw the child during the absence of the doctor in attendance, suggested also acute rheumatism. The child was sent to me on March 12th. He was an intelligent bright baby, fairly well nourished. The slightest touch to the limbs caused intense suffering. The right leg was held semi-flexed, somewhat everted, the left extended and apparently powerless. The calf of each leg was swollen, almost cylindrically.

The swelling was most marked towards the epiphysial lines. The gums were normal, with no signs of teeth appearing. There had been a streak or two of blood in the motions when the child was constipated, but nothing suggesting a hæmorrhage.

The child had been fed strictly on Allenbury's foods since birth, No. 1 from birth till three months old, then No. 2 till seven months old, and No. 3 from then to the date of being seen. In addition, a little Virol had been given from time to time during the last month or two. No anti-scorbutic precautions had been taken.

The child rapidly improved, and began to move his feet in four days, after being placed on an appropriate diet.

As the measures adopted in this case were fairly

(a) Delivered at the Polyclinic, Charles Street, London, W.C., on Tuesday, June 22nd, 1909.

typical, I will presently, when we come to talk about treatment, quote from the letter I sent to the medical attendant.

Here is a somewhat similar case from the Waterloo Hospital :—

*Case 2.*—A boy (C. M.), æt. 1 year, was admitted under Dr. Haig on November 12th, 1901, for loss of use of the legs and swelling of the right leg. The child had lost the use of its legs for five weeks. The right thigh had been swollen and tender for one month. The child had bled slightly from the gums, and there was occasional sweating from the head and chest. On admission the weight was 14 lbs.

The child had well-marked rickets and was poorly nourished. On the outer side of the right thigh was a very tender swelling, near the great trochanter. Temperature was from 100° to 102°. The condition rapidly improved under appropriate diet, and on December 2nd the child was well.

In this case the diet before the illness developed had been sterilised milk, and barley water, and Robb's biscuits.

Here you will notice that there was definite rickets, and slightly hæmorrhagic scurvy.

*Case 3.*—A slightly different case is that of a girl baby (W. S.), æt. 9 months, admitted to the Waterloo Hospital, under Dr. Rankin, on September 17th, 1906, with swelling of the left foot. The foot began to swell on September 14th, and the child was in pain. A petechial rash appeared on September 16th. The temperature was normal. There were no other signs of scurvy. The patient was well in a week.

In this case the diet had been Nestlé's milk and barley water, after the third month, when the mother had found herself no longer able to nurse the child. In this case the only bleeding was subcutaneous, and there was no rickets.

*Case 4.*—Also from Waterloo Hospital, is that of a boy baby (V. R.), æt. 9 months, admitted also under Dr. Rankin on April 4th, 1906. Swelling and tenderness of the legs had appeared about fourteen days before admission. The child was pale and flabby, but fairly well nourished. There was no sponginess of gums and the motions were natural. There were no signs of rickets, although the teeth had not appeared. There were no ecchymoses nor petechiæ anywhere. The legs were extremely tender and swollen from the knees to the ankles, and the back of each foot was shining and cedematous. Any movement caused the child to cry. The next day the child was lying still with the legs extended; there was great tenderness when touched. On the 11th, a week after admission, the child began to move the legs himself, lying with them flexed, and there was no tenderness. The swelling was going down. Five days later, on April 14th, there was some staining on the right tibia and dorsum of the foot from blood absorption. On April 29th the patient was well, and cut his first tooth.

In this case the diet had been breast milk for one month only, and afterwards Nestlé's milk for one week, when, diarrhoea and vomiting occurring, peptonised milk was given, then cow's milk and barley water; then, at four months old, Nestlé's milk and Virol, and at six months old, the Battersea municipal milk until admission. In this case also there was no rickets.

#### DIAGNOSIS.

In the diagnosis of infantile scurvy the following conditions should be differentiated :—

1. Syphilitic epiphysitis; this usually occurs in the second or third month—much earlier than scurvy. Scurvy takes months to develop.

2. The pseudo-paralysis, due to pain, has been thought to be due to spinal meningitis.

3. Traumatism. I have seen a child placed in splints for infantile scurvy.

4. Sarcoma.

5. Osteo-myelitis.

6. Acute rheumatism. "A mistake which ought never to occur, for rheumatism is practically an unknown disease under the age of eighteen months." (Still.)

7. Simple stomatitis. (In scurvy it is the gums of erupting teeth that show changes. Stomatitis is present also on cheeks and tongue.)

The chief points on which the diagnosis depends are :—

1. Tenderness of the limbs. Always bear the disease in mind.

2. Age. Never in the earliest months. Earliest case was at five months. (Still.)

3. History of diet for some months. Scurvy takes time to develop.

4. History of development of the lesions.

5. Nature of the swellings on the shafts of the bones.

6. Purple discoloration or bleeding from the gums of teeth which are at or approaching eruption.

7. Effect of anti-scorbutic diet.

#### ÆTIOLOGY.

What is the origin of these cases? All are agreed that it lies in the diet, but a difference of opinion exists as to the exact nature of the fault. Two views exist, which we may call (1) positive, and (2) negative.

The positive view is that the cause is an error in diet which leads to the development of scurvy by something deleterious being given. This opinion is upheld by the fact that cases have been recorded (Holt) where recovery has occurred on stopping certain patent foods, though still giving sterilised milk, and by the absence of scurvy amongst children fed by the sterilised milk charities in France. Certainly patent foods are often elements in the history of these cases.

The negative view is that the error in diet consists in withholding something beneficial, the not giving of a mysterious anti-scorbutic principle; this view may also be called the scorbutic theory. Its chief support is to be derived from the fact that the great majority of cases of infantile scurvy show an almost immediate improvement, and a rapid recovery under an anti-scorbutic diet of fresh organic food, including milk.

That infantile scurvy is a disease of civilisation is the broad view that emerges from this controversy as to its actual pathogeny. It occurs most frequently in the children of those who, though insufficiently informed, yet devote great care and attention to the feeding of their children. It is less common among the children of the very poor, who, though often hungry, perhaps receive a sufficient variety of experimental foods to enable them to avoid scurvy, though often acquiring enteritis in the process. Normal breast-feeding is more common also among the poorer classes. The breast in modern town-dwelling women, of all except the poorest classes, seems to be regarded much more as a mere æsthetic attribute of their sex than as one of the important organs of reproduction of the species.

Infantile scurvy is not a very common disease in children's hospitals. In three years at the Shadwell Hospital only one case was admitted as such. In fifteen years at the Waterloo Hospital only three cases were admitted as such, though, of course, cases occur occasionally in the out-patient departments. Rickets and gastro-intestinal affections

are, however, very common. It is this fact—namely, that only some children develop scurvy—that has led to the idea that they possess an idiosyncrasy. If we adopt the view that, by giving sterilised milk (with that is included pasteurised milk as a minor evil), we run the risk of causing infantile scurvy; then the present practice of heating milk before sending it out is likely to increase the liability of hand-fed infants to the disease if the fact is not recognised by the medical profession.

The whole practice of the habitual sterilisation of foods presents one of the most interesting problems of the day. It is becoming always more impossible to feed a great city with an adequate daily supply of pure fresh food. Many foods are sterilised and reach the consumer in hermetically-sealed packages. If not sterilised, the public health authorities tell us that a large proportion of the foods contain dangerous organisms, particularly so in the case of milk. The development of better methods of cold-storage, on the other hand, is an offset against the practice of sterilisation, so that, if we can regard food frozen for several weeks or months as fresh, we may presume that some of the difficulty is being overcome. Cold-storage does not destroy infection, and is not, therefore, applicable to the milk supply however.

#### PREVENTION.

In regard to the prevention of infantile scurvy, the growing use of the pasteurising machine by the first-class firms presents a new question for the parent and medical attendant in all cases of hand-feeding, always supposing that sterilisation is in itself a cause of scurvy. This is a matter of opinion. Certainly, I know many infants brought up on sterilised milk who have escaped scurvy, and any symptoms approaching it. Incidentally, I believe them also to have escaped the even greater dangers of impure milk. It is impossible in the commercial handling of milk, at a price that the public will pay, for it to be produced, carried, and sold under ideal conditions. To my mind, the counsels of perfection advocated by certain hygienists are incapable of adoption, though all must welcome greater supervision of the milk trade, such as is foreshadowed in the recently-proposed Bill of the Local Government Board.

The practical question for the medical attendant is one which has so often been discussed in medical journals: "Should milk be boiled?" The milk purveyor is answering it by taking the decision out of the doctor's hands. It is safe to assume that the bulk of the milk supplied by some of the best modern dairy companies is pasteurised for about twenty minutes at 160° F. before being sent out.

Amongst careful parents, led by specious advertisements to make use of proprietary preparations, the milk is nearly always completely cooked again in the course of making the food, and the baby will get absolutely no fresh food for months.

Under such conditions there is always a risk of the development of scurvy. This risk is certainly increased if the food given is entirely self-contained, that is, if no milk is to be added to it in preparation.

It must be admitted, in this connection, that some of the infants' patent foods possessing the best reputation are of this class. Here, again, I can say that I have seen many infants brought up entirely on these foods without the slightest evidence of marked malnutrition, such as anæmia, rickets, limb-tenderness, or scurvy. Almost all hand-fed infants have somewhat delayed dentition, so that I do not include this as evidence of disease.

As regards prevention of scurvy in children fed

on cow's milk, there are only two things the doctor can do. Either he must insist upon the use of fresh milk obtained from a reliable source, or he must use precautions by making regular additions of fresh organic food to the dietary when he knows the milk is cooked.

The first of these is by far the best, but I think extremely difficult. I need not dwell on the fallacy of so-called "nursery milk." As a material for infant-feeding, ordinary standard milk is certainly preferable, "nursery milk" being dear and usually much too rich in fat, being entirely a fancy article supplied by the milkman according to his own ideas of what is desirable. The difficulty of investigating standard milk is enormous. Milk comes to London an average distance of about two hundred miles, and is measured, mixed and poured from one vessel to another so many times before reaching the retailer that it is almost impossible to trace its source or secure its freedom from infection with certainty. Some of these faults will be remedied if the new Bill becomes law. Meanwhile, one can only say, it is best to secure good fresh milk for infant-feeding, if one can.

The second measure of prevention is, on the other hand, simple. Various substances are given, such as orange juice, grape juice, diluted lemon juice, or raw-meat juice, and the youngest children will take them greedily. This should, I think, be a routine practice where cooked milk must be used.

In this connection, I would like to repeat an observation I have often made in speaking on infant-feeding. About the time of the first dentition, we know that other important changes in the digestive apparatus are also taking place. The pancreas, for instance, begins to assume its amylolytic function. I am convinced that it is necessary to supplement the milk in many hand-fed children by the addition of one or the other of the farinaceous foods about the seventh or eighth month, so as to employ the newly-acquired activity, otherwise nutrition is likely to "hang fire."

#### CURATIVE TREATMENT.

As regards curative treatment, the following lines may be followed, which I quote from a recent letter to a practitioner:—

1. Stop preserved foods of all kinds.
2. Give two teaspoonsful of finely "creamed" mashed potatoes in the bottle twice a day.
3. Give the juice of six grapes, or a little lemon juice diluted with water, about three teaspoonsful of juice daily between meals.
4. Add at least 25 per cent. of reliable raw fresh milk, if obtainable, to each bottle.
5. Keep the child at rest when the limbs are painful, avoid dressing or undressing, and let the baby be handled only on a firm pillow or small mattress.

6. Treat the gums, if necessary, as for stomatitis. These were the lines followed in Case No. 1 that I described to you, and the progress made was of the ordinary kind in a case that recovers.

Twenty-four hours after starting the new diet the pain was less, the baby slept longer, and did not cry so much when moved.

Three days after, the foot was moved, and the legs could be handled gently, and he was in every way brighter and happier. In five days both legs were moved, and subsequent recovery was uneventful.

The danger of infantile scurvy lies wholly in the case being overlooked. There is no disease which will afford greater satisfaction to the medical attendant who recognises and treats it in the early stages. In very severe cases, when there are many hæmorrhages and the child is badly nourished or bronchitic, recovery may not occur.

It is a disease to look out for and to prevent. It is a rare disease. It is a very rare disease as a fatal affection. It is a comparatively modern disease, one of the penalties of civilisation, perhaps, and it is one which, since its real nature was described by Sir Thomas Barlow, should quickly become a mere historic fact. Babies must have milk in preference to patent foods. They must have fresh organic food. If their milk is cooked before delivery, or always cooked, as a measure of precaution, or in its preparation, or if pure dried milk is used as a diet, simple fruit juices or raw-meat juice must supplement it. In the present state of the dairy-farm industry in this country, and the condition of the milk traffic, I think properly pasteurised milk, heated and cooled again as soon as possible after arrival in London, is the best and safest, and I would infinitely prefer trying to prevent, or even to cure, infantile scurvy, to treating the more severe affections due to infection of the child's digestive organs by septic, typhoid, or tuberculous "fresh" milk. But I do not for one moment want you to think that foul milk is to be encouraged, provided it is sterilised. Cooked dirt is not much more attractive to me than raw. Some of the so-called sterilised milk supplied by badly-equipped small dairy firms is frankly poisonous, being sterilised, as an economical measure, when half decomposed, and not as a matter of hygienic precaution.

Note:—I wish to thank Dr Fowler, of the resident staff of the Royal Waterloo Hospital, for examining the notes and supplying the abstracts of cases, and Dr. Haig and Dr. Rankin for permission to quote them.—T. D. L.

NOTE.—A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by Professor Antonin Poncet, M.D., Professor of Clinical Surgery at the Faculty of Lyons, and M. Leriche, M.D., Surgical Registrar at the Lyons Faculty of Medicine. Subject: "A Study of Acute Tuberculous Rheumatism."

## ORIGINAL PAPERS.

### SYMPHYSIOTOMY AND HEBOSTEOTOMY.

By R. ERNST RUNGE, M.D.,

Assistant Physician an der Frauenklinik der Königlichen Charité.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

THE most important question for the practical obstetrician is how the obstruction caused by contracted pelvis may be avoided or removed. Up to quite recently the only outlets were induced labour, Cæsarean section, and perforation. The operative era of the last few years has made a great change in this respect. There are two operations which already, but still more in the future, justify one's hopes in this direction: symphysiotomy and, above all, pubotomy, or, as the procedure has been recently named, hebosteotomy.

Both operations pursue the aim of cutting through the rigid pelvic girdle and thereby enlarging its area. The consequence of this is that the head of the child that could not pass through the narrow opening passes the enlarged one with more or less facility.

Symphysiotomy, first proposed by Sigault, and taken up in Germany, above all, by Zweifel, consists in dividing the structures above the symphysis, and then dividing this. A gaping of the pelvic outlet is the result. As the wound in the soft parts in this procedure is rather large, Zweifel more recently tried to operate subcutaneously. Whether

in this symphysiotomy—i.e., whether separation of the cartilage of the symphysis was ever effected is doubtful. It is very easy for the saw, when introduced subcutaneously, to glide off the cartilage, and in reality divide the adjacent bone—i.e., instead of a symphysiotomy, perform a hebosteotomy. Symphysiotomy may find a place in flat, contracted pelvis, when the true conjugate is narrowed to 6.75 cm. In general contracted pelvis the limits for the operation are almost 1 cm. higher. In the opinion of Zweifel and other authors, the operation is contra-indicated in women with a febrile temperature.

Now, how is re-convalescence affected by this operation? In general, the wound heals well; that made by the saw closes with a firm cicatrix of connective tissue, so that the women are able to perform any kind of labour. It is possible, however, that a collection of secretion may set up some trouble behind the symphysis. By the open symphysiotomy this may be avoided by drainage of the prævesical space, but not with the subcutaneous operation. The period when the function of walking becomes normal depends on the healing of the wound by first intention; it usually averages about two and a half months. So far, however, unfortunately, this measure of success is not obtained in half of the cases.

And now how does the operation stand with regard to later pregnancies? Permanent widening of the pelvic ring could not be determined by Abel. On the other hand, Ihl and Theiss affirm that more than 50 per cent. of the subsequent labours are spontaneous. Other authors, such as Baisch, for instance, are of opinion that this result is frequently only obtained when a movable joint is left at the point of division. Some authors, as Meissner, Velitz and Gradenwitz, saw narrowing of the pelvic canal through the formation of callus in the cicatrix.

Let us now briefly look at the statistics. Zweifel lost 6 per cent. of his cases; according to the calculations of Meyer, the total mortality of the published cases was from 11 per cent. to 12 per cent. Neugebauer reckoned the infant mortality at 20 per cent.

A great disadvantage of symphysiotomy is that it cannot be carried out by the general practitioner, but must be reserved for hospital treatment.

That it is not a simple operation is shown by the fact that in the hands of even so skilful an operator as Zweifel, who has practised it for years, no generally satisfactory *technique* has been discovered.

Let us now turn to hebosteotomy. It is an operation of much later date than symphysiotomy, but, in spite of this, it has already found more followers than its rival. With intent, it was first performed by Gigli by means of a specially-constructed wire saw. Baumm was the first to undertake the operation in Germany, unhappily, with an unfortunate result. It would probably not have met with any further acceptance if Doederlein had not adopted it.

As regards *technique*, we must distinguish two modifications, the open and the subcutaneous operation. The first was first recommended by Gigli, and was further practised by Van de Velde and Meyer. By a transverse section through the soft parts the os pubis was exposed; Gigli's wire saw was then introduced under guidance of the finger and the bone severed.

Doederlein followed another plan with the subcutaneous method devised by himself. He makes a transverse incision over the tuberculum pubis down to the bone, and then with his finger pushes

back the tissues behind the pubes. He now passes a curved needle round the bone and brings it out near the labium majus. Other authors recommend a similar procedure. Walcher, Kanne-giesser and Bumm went a step further in carrying out the operation entirely subcutaneously. According to the description of Stoeckel, Bumm proceeds in the following manner:—A peculiar-shaped curved needle is introduced two finger breadths wide of the clitoris, between the large and the small labium, and just below the descending ramus of the pubes. The index finger of the other hand controls the point of the needle from the vagina. After the exit of the needle above the os pubis in the region of the pubic hair, Bumm's modification of the saw is hooked into an opening in the needle and withdrawn with the saw, and then with a few strokes the bone is divided. Reifferscheid and others proceed in a like manner, only they make the puncture from above.

If we compare the two methods with one another, a more exact arrest of hæmorrhage is perhaps attained by the first, but it is more complicated, and the wound is more likely to become infected. Up to a certain point the same may be said of Doederlein's method. On the other hand, the entirely subcutaneous operation is quite simple; it may be performed by the expert hand in private practice, and is as good as an absolute guard against infection.

As regards treatment of the wound, it must necessarily be more intensive in the open method. With the subcutaneous operation, a pledget of collodion or a light bandage is sufficient. Special stress must, however, be laid on the avoidance of hæmatoma in the suture canals. A firm compression bandage outwardly and a vaginal tampon protect against this. As regards after-treatment, absolute rest for the pelvis was at first considered necessary. Later, however, less importance was attached to this, owing to the notion that through a certain movability of the sawn ends of the bone a less rigid cicatrix would be obtained, which would allow permanent widening of the pelvic canal. For the first twelve hours, at least, the firm compression bandage must never be omitted, in order to make certain that no hæmatoma can form.

There has been a great dispute amongst authors as to the manner in which healing of the bone takes place. Some consider that the ends of the bones ossify; others that the union is only by means of connective tissue. During the earlier weeks the union is certainly only by connective tissue; later, most authors believe in a bony union. The most advantageous condition as regarded the future would naturally be firm union by connective tissue, as then dilatation of the pelvis for later labours might be expected with greater probability.

One disadvantage of hebosteotomy, even at the present time, is the occurrence of undesirable wounds. Considerable lacerations of the vagina have been observed rather frequently. A part of these is certainly due to rubbing through of the soft tissues by the sharp ends of the bones as the foetal head passes through the pelvis, and must be laid to the charge of the operation. Another part is due to unyieldingness of the soft parts, and these would probably have occurred even without any operation. These injuries may to some extent be avoided by not allowing the bones to gape too widely as the head of the child is passing through the pelvic canal. It is the same, but in a higher degree, as regards injuries of the bladder. These may to a certain extent be caused by the hebos-

teotomy needle, but they heal up, as Stoeckel not unjustly remarks, almost spontaneously if a catheter is left in the bladder.

In the early days people feared large losses of blood from the injured blood-vessels, especially from the bulbus cavernosus. Rosthorn had a death from this. No further unfavourable observations on this point have since been made; any bleedings that do arise are easily overcome.

A further danger of hebosteotomy, infection of the wound, is best avoided, as already mentioned, by the entirely subcutaneous operation. With a proper *technique* the wound can be as good as absolutely protected from contact with vaginal secretions, and any infection by the subcutaneous operation is, from the small size of the wound, extremely improbable.

As regards the gain in space in the pelvis after hebosteotomy, it is beyond the limits of this paper to go into the different increases of measurements of the individual cases. It depends essentially on the kind of contraction. The space at the point of division permits on an average the laying in of two to three fingers. Almost equally important is the question already mentioned, whether permanent dilatation may take place after hebosteotomy. Most authors appear to answer this question in the affirmative. Here the manner of healing of the ends of the bones is naturally of importance. If a broad callus forms between them, or only connective tissue, permanent dilatation may be looked for. If the bones unite, however, with only a small callus, no great gain need be expected.

The indications for the performance of hebosteotomy are the same as for symphysiotomy. It can never be a substitute for Cæsarean section when this is absolutely indicated. It is improper to undertake the operation when the labour seems likely to be difficult, or even impossible. It is always proper to wait to see what the uterine pains can effect. An operation will then frequently be unnecessary. It is only after careful observation of the course of the labour has shown that a less dangerous method of delivery is out of the question, and that, on the other hand, something must be done to accelerate the course of labour, that the operation becomes justifiable. It should never be undertaken, except there is a certainty that the child is alive and strong; it would be a mockery if the result was a dead child.

The standpoint that Bumm takes is, shortly, the following:—In first labours he avoids hebosteotomy wherever possible, on account of the possible great injury to the soft parts, and in place of it substitutes suprapubic Cæsarean section. In the case of multipara, he performs hebosteotomy with a true conjugate of 6.75 cm., which diameter he looks on as the lowest limit. Otherwise he does not limit himself strictly to figures in contracted pelvis, but places much more importance on want of proportion between the size of the child's head and the space in the pelvis. Thus, even in a case of normal pelvis, if the head of the child was of giant size, and there was want of proportion between the head of the child and the pelvis, he would perform hebosteotomy. Hebosteotomy is indicated in contracted pelvis, when, notwithstanding strong pains, the head of the child does not enter, when the waters escape too early, with consecutive absence of power on the part of the uterus, when the foetal head is fixed in an unfavourable position above the brim, or when there is an excessive degree of infantilism in the genital organs, associated with defective pains. Bumm does not leave the social position of the patient without consideration. If the patient has an excessive desire

The hospital is small and poorly equipped, being only intended for local needs. It falls so far short of the standard we are accustomed to in Europe as to be hardly conceivable by a European surgeon. The buildings he might think were those of a farm. The staff he would find to consist of Major Smith himself, assisted by the following natives: an assistant surgeon, a hospital assistant, and a few dressers. The staff, in fact, is not as large as that of one ward of the Edinburgh Royal Infirmary, whilst the number of patients at one time under treatment in the hospital for major operations on the eye is frequently as large as 450.

These facts are important because they indicate that the immediate results of the operation must be good. Were many of the patients to require attention daily, or even as seldom as twice a week, the organisation would break down and the "staff" would be paralysed by overwork. As a matter of fact, the cataract cases are operated upon as soon as they come to hospital in the morning. There is no preliminary treatment. There are two tables in the operating-room, and while one patient is being operated on another is being bandaged up and carried away. The great majority of them are not dressed again till the eighth day, and receive their discharge on that day. Thus there is a minimum of dressing.

The assistant surgeon, on his daily rounds, finds out any case suffering from indications of post-operative complication, and attends to him. The dieting is simple food of the people, sold to the patients and the friends who look after them by a man from the bazaar. The very poor get a ticket entitling them to get food at the hospital expense. Only about 3 per cent. get free diet. All the nursing is done by the friends of the patient. The fact, then, that under such conditions these same patients and their friends, having left the hospital, are so satisfied with the result that they in their turn send their friends to the same place in such astonishing numbers, shows, to my mind, that the operation is emphatically a good one, and that its after-results are better than those hitherto attained by any other operator in the Punjab. And when I say any other operator in the Punjab, I might just as well say any other operator in the world, for I do not think that operators on cataract are anywhere else more experienced.

In view of these facts, any *a priori* reasoning designed to show that the after-results of the operation must be bad may be disregarded; and that gloomy prognostications are, moreover, disproved by the excellent after-results which have been noted by myself and others in patients operated on by Major Smith from one to six years previously. The usual appearance is that of a clear black pupil and a brilliant eye; and vision with correcting glasses is usually 6/6.

Major Smith's fame amongst these poor and ignorant people extends a long way. At his hospital I have seen Afghans from Cabul, men from the sea-coast of Karachi, from the wilds of the Himalayas, the desert plains of Sind, and the more fertile regions of the Ganges. And this fame has all been attained by a knowledge of how to use a couple of blunt hooks in the extraction of cataract.

Again, it is interesting to note that there is no selection of cases. Indeed, a European surgeon might well be appalled by the unfavourable condition of many of the eyes operated upon. And there is no doubt, did circumstances permit, that many of the cases would receive preliminary treatment if it could be given to them. But for several reasons in Major Smith's practice, such treatment cannot be given.

Eyes which offer any hope of vision are operated on, having regard to the principle that some vision is better than none at all. The following classes of eyes are operated upon:—Eyes with old trachoma and blepharitis; glaucomatous eyes; eyes whose lenses have been couched and have a consequent atrophy of the retina and night blindness; eyes with iris adherent to the lens; and eyes in every stage of cataractous degeneration from the first hazy beginnings to complete atrophy. If both eyes are cataractous, both are done at the same sitting. Combining these unfavourable conditions with the great popularity of the operation, there follows but one conclusion, and that is, that in Major Smith's hands it is an eminently sound one and the operation of choice.

If we grant this, it comes to be a question whether it is Major Smith, and he alone, who can do the operation. The operation would not be of much use to the progress of the surgical art if only one man could do it. And I may here state without preamble that there is no jugglery about it. It would be hopeless for the ordinary man to attempt to imitate a Leoncavallo. None may aspire to play billiards like Roberts, to sing like a Caruso or a De Retzke, to play the violin like Paganini, or to walk the tight-rope with the assurance of Blondin. But Major Smith's performance is comparable with none of these. It does not require a special genius. What Major Smith can do others may do also, provided they are properly taught and can get a sufficient amount of practice. The ordinary man cannot hope to quite attain Major Smith's skill, because he will not be able to get so much practice or experience as Major Smith has had. But with an experience of about two hundred operations, he will attain sufficient skill for practical purposes. A beginner must have good manual dexterity, as anyone professing to be an ophthalmic surgeon should have; and he should be taught how to do the operation in actual practice by one who can do it well himself.

I am speaking from personal experience, because I have been taught to do the operation by Major Smith himself, who has kindly allowed me to do over 500 operations under his personal supervision, and who has taught me every detail to be learned in the manipulation of the various kinds of eyes. I have attended Major Smith's clinique during the last three years. Prior to this I had occasionally attempted the operation, but with indifferent success, as I did not know how to do it. The first extraction in the capsule I ever saw done was done by myself, or, rather, by the patient. It was one of my early operations, and was intended to be done in the usual way with capsulotomy. When I had made the incision, probably none too skilfully, the patient, an old woman, powerfully screwed up her eye and delivered the lens neatly upon her cheek. There was no prolapse of iris nor escape of vitreous; the pupil was round and small and central and jet black. The wound healed rapidly and without any complication, and the result was what one might call ideal. Pleased with this first extraction in the capsule I endeavoured to repeat the performance. Sometimes I was successful, but rather oftener, I think, I made a hash of it. I either burst the capsule or I had to do a capsulotomy to avoid using what I considered to be unjustifiable force; or I lost vitreous and had to shut up the eye without inquiring too closely into the position of the iris.

When, three years ago, I first saw Major Smith operate, I realised that I had not known how to do the operation. I watched Major Smith operating for a long time, and studied his methods as

closely as I could. But when I went back to my own hospital and tried to do the operation, I found, somewhat to my disappointment and astonishment, that I was not much better at it than I was before. When I saw Major Smith doing it, it all seemed simple and easy. When I tried it myself all sorts of distressing things used to happen.

I used to watch lens after lens being extracted entire in its capsule, smooth and glistening, some mature and ripe, others only just beginning to be opaque, and a few the dense black cataracts; some with big and some with small nuclei, some hard and thin, others round and soft and fat. Out they came and into the bottle, lens after lens, without a hitch.

#### TECHNIQUE OF THE OPERATION.

Then Major Smith began to teach me by allowing me to operate myself under his direction. It is the only way to learn, and I shall always rest under a deep debt of gratitude to Major Smith for his kindness in teaching me, and for the pains he has taken to render me proficient.

The first thing of which I became aware was that it was much easier to operate in Smith's hospital than in my own. The reason was that the assistant knew exactly what to do. The first lesson, then, is that the assistant is almost as important as the operator. Next I found that there was something to learn at almost every stage of the operation. There were many little things which I had failed to notice, despite the large number of times I had seen the operation performed. These little things are important that they conduce to a smooth and even operation without complications and distractions, and hence lead to a good result. Major Smith's *technique* is such that it may be said to avoid all complications, and in this lies the secret of its success. The eye is quickly and gently dealt with, and it shows its gratitude by its good behaviour, both at the time of the operation and afterwards. I have now done over 500 extractions in the capsule as a pupil of Major Smith's. He has also taught three other surgeons. The two whom I know and myself can do the operation with ease and confidence, and with almost uniform success. Of the other operator, Knapp, of America, I cannot speak from personal knowledge. The operation, then, can be done by others besides Major Smith, and the failure of these ophthalmic surgeons who have tried to do the operation and have not met with success is due to their fault of *technique*, and not to the fault of the operation. There is a great deal to learn as to "how" to do the operation, and I can fully endorse Major Smith's claim that he has evolved the *technique* of the operation.

Such, then, is an account of Major Smith and his operation. I speak from personal observation and experience of Major Smith's practice at Jullunder during the last three years, and he has very kindly allowed me to do about 500 extractions in the capsule on his patients, and has thoroughly taught me how to do it. Having been put in the right way by a master, I have had a very gratifying success, and a relative immunity from disaster or complications. My own cases, unlike Major Smith's, have been more or less selected ones, as Major Smith himself has always done the cases where there was glaucoma or a previous dislocation of the lens.

I wish to absolutely endorse what Major Smith says as to the advantages of his operation, and I would lay it down that—except in patients under twenty-five years of age—it is the best operation for nearly all cataracts, and that it is the operation of election in immature cataract, and that the time of election for the performance of the operation of

cataract extraction is when the cataract is immature, because then the operation of extraction of cataract in the capsule is easiest to perform, and is then least likely to be fraught with complications, either immediate or remote.

The general acceptance of such a doctrine will mean a very great change in the present methods of treating cataract; and it will mark a very great advance.

## HEART TONICS AND VICHY WATER IN THE TREATMENT OF MORPHINISM.

By W. OSCAR JENNINGS, M.D.,

Of Paris.

FOR many years I have been using heart tonics and bicarbonate of soda in morphinism, not as a "cure," but as part of the treatment which remedies the physiological disturbances, caused by suppression, and which, by alleviating two of the principal factors of craving, reduces the otherwise intolerable wretchedness of an ordinary weaning to a perfectly bearable minimum.

The importance of these therapeutic measures was confirmed by the late Prof. Gamgee, who, following upon the same lines as myself, has insisted upon the necessity of the recognition of the "multiple causation of craving" of the "three modes of treatment," which are the same as mine, indicated by the three "great groups of symptoms."

In expressing this opinion Professor Gamgee has, it may be said, come to a conclusion that has long been adopted universally abroad, but he does not express the views of the majority of English writers, some of whom, justly looked upon by the profession as authorities, have declared that these same means of treatment are useless.

Sir Clifford Allbutt and Dr. Rolleston, for instance, state that they have tried them, "but we have not," they say, "found them useful."

Before discussing further this "physiological" part of the treatment of the morphia habit, it may be remarked that it is useless to attempt the cure by any means of a morphia patient with a wrong mentality—that is to say, of one who does not really *intend* to give up the addiction if he can be helped efficiently.

On the other hand, in morphinism, mentality is conditioned as much by sub-consciousness as consciousness, and the success of a morphia weaning will always turn upon physiological treatment, for when the somatic substratum is freed from the greater part of the discomfort arising from perverted function, the *hantise* previously caused by organic malaise will be relieved, and with it the unconquerable obsession.

It is by this means, associated with progressive voluntary renunciation, that I have within the last ten years been able to obtain 90 per cent. of successful results in the cases—nearly always apparently hopeless ones—which have been under my care. In one of the most recent morphia had been taken for a quarter of a century altogether, and continuously for the last twenty years.

On the other hand, many of my patients, almost invariably distinguished medical men, had previously been unsuccessful chiefly in consequence of the non-adoption of these means, having been nearly always discouraged from using them by the perusal of Sir Clifford Allbutt's monograph on "Morphinism." (a)

As, then, for every known morphia *habitué* ticketed as a "fiend" there are at least twice as many unsuspected users of the drug, both in the medical profession and outside—unsuspected because they know the futility of applying for ordinary medical advice, and who would yet gladly be free, the importance of rectifying so grave an error concerning such a widespread and generally hopeless condition is obvious.

#### 1.—HEART TONICS.

Sir Clifford Allbutt and Dr. Rolleston contest the indication for heart tonics in morphia suppression, and

(a) One case of the kind was quoted by me in my paper in the *Lancet*, August 10th, 1901.

deny the tonic action of sparteine on the heart entirely. They say that the first of the tracings given in my memoir, and here reproduced with the plateau I have described, taken at the time of craving, only shows increased tension—that the effect of sparteine, as of morphine, is to lower tension, as they say, is proved by the second and third sphygmograms. Huchard, on the contrary, is of opinion that the general condition in chronic morphinism is one of hypotension, and the clinical observation of morphia patients demonstrates that at the moment when the tracing with flattened apex is taken, the tension is at its minimum.

Instead of contraction of the arterioles and capillaries, as supposed by Sir C. Allbutt, there is, as a matter of fact, at this time vaso-paretic dilatation, as any clinical observer can recognise, with sluggish circulation, semi-stasis by vaso-motor asthenia—morphinopriva, corresponding to the weakness of cardiac impulse, due to deficient innervation of the heart from the same cause.

This paretic condition, due to want of an accustomed stimulant—to relative amorphinism—is instantly relieved by morphine, which, in *habitués*, at the moment of administration, is a transcendental tonic, or by sparteine, which then gives identically the same tracings as digitalis, a fact which tends to show that in morphia addicts, morphine and sparteine, as well as digitalis, are tonics of the heart. The flattened pulse of craving, which, under some circumstances—kidney disease, for example—would indicate high tension, has no such meaning in amorphinism.

At this moment it indicates, as far as the heart is concerned, diminished impulse, as in the absorption of a large part of the tidal wave by aortic aneurism. There is, then, hypotension in amorphinism, and restoration of systolic pressure and of tonicity, by morphine and sparteine, which can be easily determined by the sphygmomanometer, or by any of the simpler instruments for estimating tension.

Sphygmographic tracings do not always give positive evidence. They may require interpretation. The same tracings can be obtained in exactly the same conditions, but similar ones may be obtained under different circumstances when there are opposite and compensating conditions. (a)

But even supposing that the action of sparteine were not, as has been shown to be the case by Laborde, Pouchet, and other competent observers, that of a direct cardiac tonic under ordinary conditions, and that it were only a lowerer of tension, it is a mistake to suppose that drugs which lower tension cannot have a tonic effect on the heart. They may do so even in a patient who does not take morphia, when, by relieving the strain, and lessening the required effort, they will rest and strengthen the tired organ.

(a) Dr. Haig, it is true, in the *British Medical Journal* of 1889, and in his work upon "Uric Acid," gives tracings similar to the above, and states that they show low tension under the influence of morphia, which clears the blood of acid, and high tension during the "opium rebound." During the low tension, that is, under the influence of morphia, "the patient is happy and comfortable, and without sexual desire; during the rebound, when there is collemia, the reverse condition obtains, high tension, wretchedness, and sexual excitement."

As Sir Clifford Allbutt has most likely taken Dr. Haig as his authority, it may be pointed out that the tracings given by this author were obtained after the administration of morphia or opium in non-addicts, and that the action in such a case is exactly the opposite to what we observe in morphinism.

The high-tension tracing was obtained after "a dose of opium over-night." His other observations show the effect of two successive doses of 16 of a grain of tartarate of morphia (which is equal to about one-tenth of a grain of hydro-chlorate), or of small doses of opium, of morphia (on himself), "not continued for more than a day or two."

It is evident that Dr. Haig was entirely unaware that the action of morphia is quite different in addicts to what it is in non-addicts. In accordance with his theory, he finds that the clearance of the blood from acid by morphia causes low tension, well-being, and lessened or complete abeyance of sexual appetite.

But morphia and sparteine do not act in this way in morphinism. The condition of the arterioles and the capillaries in a morphia addict at the time of craving not being one of spasm or contraction, as Sir Clifford Allbutt thinks, but of ischæmic dilatation from slowing of chemico-vital action, the effect of the drugs mentioned can only be to restore tonicity and to replace passive congestion by active hyperæmia.

To show this, however, by the sphygmograph, the tracings must be taken at the right moment—that is, when the patient is sufficiently uncomfortable to require relief. Such was the case when the first of the three following sphygmograms was taken. The

FIG. 1.—Pulse of morphia craving.

FIG. 2.—Pulse of morphia *habitué* restored by morphia.

FIG. 3.—Pulse of morphia *habitué* restored by sparteine.

second shows the effect of morphia, the third that of sparteine, under the same conditions, a tracing taken just before its administration having given precisely the same appearance as No. 1. (a)

Sparteine acts, then, in morphia suppression, like morphia, as a perfect and immediate heart tonic, and besides the evidence of physiologists and of my patients, who constantly affirm that sparteine enables them to walk up hills or to take active exercise which would otherwise have been impossible. (b) The universal experience of specialists is conclusive.

With the collemia of the "morphia rebound" high tension and general misery, and uncontrollable desire. But if this is true of addicts, and Dr. Haig quotes a case in point, mentioned by me in *L'Encéphale*, the exact reverse occurs in persons unaccustomed to opiates, and even for some time with small doses. Morphia, which in the non-addict lowers tension, ought, therefore, to clear the blood, but instead of being anaphrodisiac, it has entirely the opposite effect, as every morphia *habitué* knows.

In a former memoir I have discussed this matter more fully, and have shown that in the world of pleasure it is the fact of this increased vigour that leads so many recent converts to the syringe to become propagandists of their new cult. The presence, then, or the absence of acid in the blood, has not so much to do with sexual desire as Dr. Haig supposes, and this shows that he, and Sir Clifford Allbutt, experimenting after him no doubt in non-addicts, have confused the consequences of two totally opposite conditions.

(a) "The observations upon the sphygmographic tracing of the pulse of habitués, we believe," says Dr. Crothers, "have laid the physiological basis for a rational system of medication. Sparteine and Caffein," he adds, "are very effectual in many cases."

(b) The only cases in which I have found sparteine in ordinary doses (gr.  $\frac{1}{2}$ —gr.  $\frac{3}{4}$ ) *unsuitable*, have been those in which there was high tension from excessive use of tobacco, and it is in these precisely that it ought to be most useful, if sparteine were a lowerer of tension. In one patient, the tension as shown by the Riva-Rocci sphygmomanometer was above the normal. In this case cigars had been smoked all day long, and the ordinary dose of sparteine gave rise to intolerable headache. It may be remarked that sparteine in the usual dose is always badly borne by those who use tobacco in excess, and is in this way the touchstone of nicotine poisoning.

It is evident, then, that in condemning in their compilation a means of relief which constitutes, as Professor Gamgee recognises, one of the most formal indications of treatment, and in stating that sparteine only lowers tension, that it does not have a tonic action on the heart, and that it consequently is not useful in morphinism, Sir Clifford Allbutt and Dr. Rolleston have come to a most mischievous conclusion. It is evident, also, that the original results, now generally admitted, of Germain Sée, who says that it is dynamogenic; of Laborde, who calls it the "metronome of the heart"; and of Pouchet, that it is incontestably a heart tonic, accepted by most English pharmacologists (a), must be taken as the more accurate.

## 2.—BICARBONATE OF SODA: VICHY WATER.

In my last edition (1901) I called attention to the fact that this, in my opinion, most valuable symptomatic treatment of the gastric and general hyperacidity of suppression had been by Erlenmeyer improperly magnified into a method to which he had given the pretentious name of "chemical demorphinisation."

Sir Clifford Allbutt, who knew nothing of this, and who takes Erlenmeyer as an authority, quotes him as recommending a totally different treatment, which he had long before renounced. He had not thought it necessary to discuss in his "Practice of Medicine" the method by bicarbonate of soda, "as he had," he said, "looked upon it only as a fad."

As a complete method of treatment there is no doubt that it is, to say the least, an exaggeration, a hasty generalisation, but the testimony of specialists to its symptomatic value is unanimous and so conclusive, and it is surprising to find that in his last edition Sir Clifford Allbutt still remains ignorant of the facts of the case, and still continues to deny the value of Vichy water.

To the evidence I brought forward in my last edition it would be easy to add other authorities sufficient to make a small volume, but, before bringing forward this kind of proof of its value, it will be interesting to explain its mode of action in morphinism, and show, as in the case of sparteine, that it could not fail to be useful.

The morphia habit is a toxic neurasthenia, a disease of over-stimulation, and outside the special indications for cardiac tonics, for a flagging heart deprived of its accustomed stimulation, nearly all of the other somatic symptoms may be looked upon as *nervo-katabolic*. They react upon one another as the *ensemble* of the somatic disturbances of function react upon psychism.

The result of over-stimulation is to produce metabolic perversion and to cause fatigue, and the fatigue of the nervous centres in its turn causes katabolic insufficiency, the formation of acids, which keep up a condition of nervous exhaustion by chemical changes of the cells. I first suggested this as a factor of morphia craving in 1887. Two years afterwards Dr. Haig found excess of acid in morphinism, and it is now admitted that fatigue, whether physical or mental, gives rise to the formation of acids, and that stimulation consists of abnormal elicitation of energy, leaving afterwards reactive depression and (with morphia addicts) exhaustion. In ordinary healthy tiredness the acids (phosphoric, lactic, carbonic) are soon eliminated, but when fatigue becomes more or less permanent, as in the toxic-asthenia of morphinism, the nuclei of the neurones, which in their normal condition are alkaline, become acid, and this can be shown histologically. The same thing is true of the muscles of the organism generally. Whenever a tired organ is examined histo-chemically the acid reaction will be found.

As I am confining myself to the question of acidity, I will say nothing of the other products of metabolic perversion, which may all help to cause fatigue. But, as in other cases of slowed nutrition, diabetes, for example, there are many intermediary products of imperfect combustion which can be found in the urine, the more perfect oxidation of which, together with the relief of the discomfort caused by them, can be promoted by bicarbonate of soda.

I have alluded to the abundance of documentary evidence on this subject, and if I insist somewhat

strongly upon this point, it is because, although Vichy water is not *per se* a "cure" for morphinism, each factor of treatment conditioning the efficacy of the *ensemble* of the measures employed, its administration will make all the difference in the comfort during weaning, and its omission may turn the scale to failure instead of to success.

In a paper read at the Paris Société de Thérapeutique, in 1906, on "The Treatment of Chronic Intoxication by Morphia and Opium, and the 'Vichy Cure,'" by Dr. Lebeaupin, the author, a specialist at Vichy, stated that he had frequently tried my plan of treatment, "et nous n'avons jamais eu qu'à nous louer," he adds, "des résultats obtenus."

"The use of Vichy water," he says, "taken at the spring, is the best remedy for general hyperacidity resulting from the state of craving which accompanies weaning. In all patients intoxicated by opium or morphine, abstinence gives rise to hyperacidity of the stomach, weakening of the heart, and nervous irritability."

"Hyperacidity of the stomach is a fact which has been recognised for some time, and to combat this acidity the use of alkalines is obviously indicated, and particularly bi-carbonate of soda."

"Erlenmeyer," he says, moreover, "has appropriated this idea, and describes under the name of 'chemical demorphinisation' a treatment which is in reality a part of the method of another author."

"The best way of giving this salt consists in prescribing Vichy water as he recommends, and Guimbail declares also that alkalines should be given 'particularly in the form of Vichy water.' Bicarbonate, also, acts upon stasis, and it is, moreover, a powerful tonic of the heart and the circulation, at a time when it is necessary to act upon a vaso-dilatation, which, as it is caused by general acidity, is helped by the tonic action of bicarbonate supplementing that of digitalis, and of sparteine, which, as we have seen, form one of the terms of our 'therapeutic triad.'"

Jardet and Nivière, in their communication to the International Congress of Hydrology (1896), also pointed out the beneficial action of this water in chronic intoxication by opium and morphia. "They do not consider, however," says Lebeaupin, "that it constitutes a complete treatment. The cure of Vichy, as generally practised, is not sufficient alone, but if, as we have seen, alkaline waters enter for a large part into the therapeutic means to be employed, they do not constitute a complete method."

"Heart tonics," he goes on to say, "and especially hydropathic measures, are also necessary, not to mention accessory medication, rectal injections, suitable conditions of existence and general management, which must be employed concurrently with the three great indications of the method."

This opinion is now universally accepted by French writers, and in all modern text-books heart tonics and Vichy water are indicated as essential elements of the therapeutic treatment. (a)

It has been said that the use of bicarbonate has been exaggerated under the name of "chemical demorphinisation" into an independent treatment, and after Erlenmeyer the late Professor Joffroy declared himself, some ten years ago, in favour of this so-called "method." It was this exaggeration that no doubt delayed the recognition by others than specialists of the value of Vichy water as a symptomatic treatment.

It must, however, be pointed out that in some exceptional cases, which, of course, do not prove the rule, those who are determined to give up the use of morphia if they can obtain sufficient relief have sometimes found that Vichy water was all that was necessary to diminish the general discomfort to a degree compatible with renunciation. Dr. G. Clermont, in a recent article published in the *Centre Médical*, quotes Glenard, who has reported a case, the interest of which resides in the fact that this mineral water was given by hypodermic injections. The patient in question, a

(a) Crothers, who fitly represents American medicine (*op cit*), says: "Great stress is laid upon the use during the entire treatment of preparations of soda to prevent or neutralise the acidity of the stomach or bowels. This is very essential in all methods of treatment."

(a) See Martindale's "Extra Pharmacopœia."

physician, "about 30 years old, was suffering from 'hepatic paludic neurasthenia,'" and for a year he had been injecting under the skin every day 10 centigrams of morphine, and, further, took chloral or bromidia. He had symptoms of anorexia, insomnia, weakness, vertigo, headache; he had lost 22 lb. in weight; the liver was supple, ptosed, and sensitive to pressure. He subjected himself to the following treatment: 600 gr. every day of Grand Grille water, and 7 gr. of sulphate of soda every morning; restricted diet, cold douches, and every day two hypodermic injections (morning and evening) of Grande Grille water.

He took at first 1 gramme at each injection, afterwards 3 grammes; the third day 5 grammes, the fourth day 10 grammes, the following day he gave himself an injection of 40 grammes, then 60, and afterwards, between the sixteenth and twentieth day, 90 grammes every day. There was never the least local reaction, but on the first days he felt several times, ten minutes after the injection, a sensation of excitement, followed after fifteen minutes by one or two hours' depression. From the eighth day appetite and strength returned.

He reduced the morphine to 3 centigrammes; on the twelfth and thirteenth day some gastric pains (thermal crisis) obliged him to give up for a time the ingestion of water, but not the hypodermic injections.

From the fourteenth day there was general improvement, which increased to the end, but his weight had decreased by 4 lb.

"I saw our *confrère*," said Dr. Glenard, "again a month later in Paris. He was well, and his weight had gone up 6 lb. He had no more symptoms of depression, the injections of morphine were abandoned."

"Glenard's observations," says Clermont, "lead us to suppose that Vichy water, by hypodermic means, has a useful action in a cure of demorphinisation," a conclusion which I can endorse completely. (a)

### A NOTE ON ACROMEGALY.

By J. C. MCWALTER, M.A., F.F.P. AND S.GLAS.,  
M.D.BRUX.,

Examiner in Materia Medica at Apothecaries' Hall, Dublin.

THE general practitioner is described in journals like the *Daily Mail* as the man in actual practice. Medicine as known to the practitioner is one thing; as known to the professor of pathology or the operating surgeon quite another thing. Dante said of Aristotle that "he saw life steadily, and saw it whole." Herein we can emulate the great philosopher; we can see the history of the patient steadily—and see it whole. Thus one may read of the pæans of joy of the operative surgeon over his fifty cases of gastro-enterostomy sent out cured, without a death; but the mere practitioner sees most of these cases get as bad as ever after a year or two, or die in the work-house ward. He also sees that cases quite as bad, and not operated on, are probably much better after an equal interval of time. Lately we are being told on high authority that there is a certain self-limitation about cancer. There is not one of us but has known of such cases, but we feared to state our experience against the *dii majores* of the hospitals.

The chief reason why the general practitioner's opinion does not command respect is that he fails to commit his experiences to print. Thus the accumulated wisdom of the individual dies with himself, and posterity gains nothing from it; further, the fewness of the articles from practising physicians tends to create an impression of their unimportance. Hence, although I know that descriptions of cases are deadly dreary stuff, I venture to describe a case of acromegaly now under my care.

(a) Glenard says that Vichy water is nearly iso-tonic, that the proportion of mineral substance in it is the same as is adopted for the composition of artificial serums. Its use as a serum would be rational, for the doctrine of sero-therapeutics admits a dynamic action of a stimulus which develops the potential activity of the leucocytes.

This dynamic action would be greater in natural mineral waters, inasmuch that, besides other vitalising principles, they contain argon and helium, as well as being radio-active, and their efficacy in small doses might certainly be greater by hypodermic injection, than when given by the stomach.

Acromegaly, as the name implies, is a chronic affection in which the extremities of the body—the hands, the feet, the face, the head—become greatly enlarged. It was first described by Marie in 1886, and since that time some 240 cases have been recorded. Though the pathology is unknown, many believe it to be connected with an hypertrophy of the pituitary body.

My patient is a man over 50, and a casual glance shows nothing abnormal except a certain awkwardness of gait and a somewhat hydrocephalic appearance of the head. Minuter examination shows that the cranium is enormously large, and the patient states that for years past he has been compelled to wear bigger and bigger hats. Unlike the majority of recorded cases, the growth is by no means so great in the upper or lower jaws as in the cranial bones. On further inspection, the left clavicle is seen to be enormously enlarged, whilst the right bones appear comparatively normal. Excessive hypertrophy is next observed in the right wrist and on the crests of the ilium. I happen to have another man with acromegaly under observation; he is a coachman, who enjoys fair health except for occasional headache and giddiness; but in his case the jaw-bones are enlarged, giving his face a long, lantern aspect, whilst his hands and arms appear to be uniformly hypertrophied. The first patient does not complain of headache—though it is a common symptom—but of shortness of breath, a feeling of extreme prostration—in spite of a good appetite—and a feeling of dread in walking the streets. His thorax appears abnormally rigid, but no cardiac or pulmonary trouble can be detected, and the occasional dyspnoea is probably due to flatulence. In acromegaly, as a rule, the sense of hearing presents no anomalies whatever, but in this case deafness was marked and troublesome. Nervous symptoms are usually rare, but this man was frequently depressed, somewhat hypochondriacal, and acutely conscious of his condition. Appetite was variable, but frequently good; the skin of the forehead and face was darkened, coarse, and apparently thickened. A gloomily lachrymose expression of countenance became constant. The lower lip seemed notably enlarged, the tongue hypertrophic, and the speech slow rather than awkward or clumsy. The chest was somewhat enlarged, and the pelvis broader, but the abdomen somewhat flattened. The general movements were awkward, the grip of the hand weak, and the patient very easily fatigued. A tendency to somnolence existed, but no very marked loss of memory, and no suggestion of dementia.

Dercum, of Philadelphia, states that preparations of the thyroid gland are without effect in acromegaly. This is not my experience in the present case. The patient had been on thyroid treatment but a very short time when very considerable improvement was noted—in fact, it appeared to give satisfactory results much sooner than desiccated pituitary gland, which is the recognised treatment. One case, of course, goes for little in establishing the effect of a remedy, but the therapeutic effects of drugs in this disease have hitherto proved so disappointing that any definite result ought to be recorded.

### OPERATING THEATRES.

#### GUY'S HOSPITAL.

APPENDICITIS WITH SPREADING PERITONITIS.—MR. R. P. ROWLANDS operated on a boy, æt. 9, who was suffering from acute appendicitis. There was no history of previous attack. The patient was admitted into hospital twenty hours after the onset of the first symptom; this was acute abdominal pain, which was soon followed by vomiting. On admission the temperature was 101°, the pulse 110; the face was flushed, and the abdomen, especially in the right lower portion, was rigid, fixed, and exquisitely tender. No lump could be felt; the resonance of the right iliac region was slightly impaired. Upon rectal examination, an indefinite, tender swelling could be felt on the right side of the pelvic brim; there was marked leucocytosis. The patient was restless. Immediate operation was decided upon. The abdomen was opened at

the lower part of right rectus, and thin sero-pus at once escaped. Gauze pads were passed first into left flank and then into the pelvis, and left *in situ*, while the cæcum and appendix were sought for. These structures were found lying on the right side of the pelvic brim, with the appendix hanging into the pelvis. There were no adhesions, so they were easily brought out into the wound and packed off. The meso-appendix was clamped, divided, and ligatured with catgut; the root of the appendix was crushed with large Spencer Wells forceps, divided, and inverted by means of a sero-muscular pulse-string catgut suture placed in the cæcum. The abdomen was cleansed with mops moistened in saline solution, the pad was withdrawn, and the abdomen entirely closed in three layers of sutures.

Mr. Rowlands said it was generally admitted to be advisable to remove the appendix in the interval after one definite attack, because one attack is known to predispose to another, and no one can foretell whether the second attack may not be grave, or even fatal. There is not the same unanimity as to the treatment to be adopted during an attack. He felt strongly that the best course is to operate as soon as the diagnosis is made, and, if possible, within twelve hours, or, failing this, within twenty-four hours of the first symptom. By adopting this course, a mortality of from 14 to 20 per cent. (as given by physicians of authority) ought to be reduced to about 2 per cent. in all cases seen in time. This plan, which he recommended, nearly always avoids dangerous and troublesome complications, and saves much time, anxiety, and expense. Prominent amongst the dangerous complications referred to are spreading peritonitis, localised abscess, empyæma, and other pulmonary complications, and sub-diaphragmatic abscess, vascular infections, especially portal pyæmia or pyelo-phlebitis, intestinal adhesions with secondary intestinal obstruction from bands, etc. Some of the troublesome ones that may be mentioned are ventral hernia and chronic constipation. By operating early nearly all these can be avoided, for usually the appendix can be easily found and removed in a few minutes, the abdomen thoroughly cleaned before the peritoneum has become extensively and deeply infected, and the abdominal wound can be entirely closed in the great majority of cases at this stage, with the obvious advantages he had already mentioned. When an operation is undertaken after about 24 or 36 hours it is a more difficult and dangerous matter, and the abdominal cavity has to be drained in many cases; so that at this stage it is an open question whether it is better to operate at once or to wait for the interval. If the signs and symptoms are not getting worse he generally prefers to wait, but only on condition that the patient be very carefully watched and be within reach of immediate surgical aid, in case symptoms of peritonitis or abscess supervene. Prominent among the alarming symptoms may be mentioned: increasing rigidity, tenderness and pain in the abdomen, vomiting, quickening pulse, increasing temperature, or sudden collapse, profuse sweating, and leucocytosis. These symptoms call for immediate operation. In such cases he believes it is nearly always wise to remove the appendix, and not merely to drain, as some surgeons recommend. Removal of the appendix can add very little to the danger of the operation if the pus be freely mopped away first, and any healthy part of the peritoneum protected by careful packing. Whenever possible in these late cases calling for drainage he drains through the vagina in women and the loin in men, in order to avoid ventral hernia and to hasten the recovery.

Ten days after the operation the patient is convalescent, not having had a bad symptom. The wound is entirely healed. He has, in fact, as these early cases do, behaved just like all patients who are operated on in the interval.

THE whole of the elementary schools of Wolverhampton, numbering about thirty, were ordered to be closed on account of an epidemic of measles. Over 17,000 children are on the registers, and a large number are affected. In one school alone one-third of the children are down with the complaint.

## SPECIAL REPORTS.

### REPORTS OF THE INSPECTORS OF LUNATICS AND THE REGISTRAR-GENERAL FOR IRELAND.

THE Annual Report of the Inspectors of Lunatics in Ireland was laid on the table of the House of Commons during the past week. It shows that the number of insane in district, criminal, and private asylums in Ireland was, on January 1st, 1909, 23,931, being an increase of 213 over the corresponding figures for the previous year.

During 1908 the numbers in district and auxiliary asylums increased by 527, those in the Dundrum Criminal Lunatic Asylum by 10, and the Chancery patients in unlicensed houses by 13, while the numbers in workhouses decreased by 330, and those in the private asylums and institutions for the insane by 7.

A table giving the number and distribution of all lunatics under care on December 31st of each year from 1880 to 1908 shows that in this interval of time an increase of 10,949 has taken place in the total inmates of district and auxiliary asylums; the criminal lunatics in Dundrum Asylum have decreased by 9; the patients in private asylums and institutions have increased by 241, while the pauper lunatics in workhouses have decreased by 790.

The decrease in the number in workhouses, which has been steadily taking place for several years past, still continues, and the number remaining in these institutions at the end of 1908 was considerably lower than at any time since the first year shown in the table—viz., 1880.

The increase in the total number of the insane under care at the end of 1908, as compared with the number remaining at the end of the previous year, might lead to the erroneous impression that an absolute increase of insanity had taken place amongst the community; but, in reality, the numerical increase is mainly the indirect result of transfers from one class of institution to another—i.e., the transfers to asylums of the inmates of the imbecile wards of workhouses. As no certificates of insanity are required for the cases maintained in workhouses, the vacancies caused by such transfers are quickly filled up by paupers suffering from the mental decay of old age, and these cases, which were not previously classified as insane, are then, for the first time, returned among the insane inmates of the workhouses—thus swelling unduly the number of the insane under care. During the year 1908, 816 cases were transferred from workhouses to asylums—being over 21 per cent. of the total number of admissions to the latter institutions. This percentage was higher than that of any year since 1904.

In the Commissioners' annual reports from year to year they have dealt with the prevalence of tubercular disease in the asylums of Ireland. That tubercular disease should be so frequently met with in these establishments is not strange, having regard to the close connection between tubercle and insanity. Both are stigmata of degeneration, in certain cases, either breaking out simultaneously in different members of the same family or attacking at different times and at different ages those who have the same hereditary seeds of degeneration. "It must be admitted," continues the report, "that, having regard to the small number of post-mortem examinations in the asylums of this country, and the recognised difficulties attending the examination of the insane, our statistics do not disclose the full effects of the ravages of this insidious malady. A high proportion of tubercular disease in some asylums might be due either (1) to the patients being received from a part of the country where it is prevalent, or (2) to its propagation in the asylum, as the disease, having been once introduced, would be easily propagated in surroundings where, in many cases, owing to the overcrowded conditions which prevail, the infection would rapidly spread amongst a class of people whose constitution renders them a ready prey to the ravages of the disease."

The Annual Report of the Registrar-General for Ireland has also been issued, and although the full text is not as yet available, a few figures may be of interest to our readers pending a fuller notice of the Report.

The return for the year 1908 show that the excess of births over deaths was 25,148, and that the loss by emigration amounted to 23,295 (which number is less than the number of emigrants enumerated in 1907—namely, 39,092, and also the average number—38,036—for the ten years, 1898-1907). There would, according to these figures, appear to have been an increase of 1,853 in the population on December 31st, 1908. With respect to immigration, there is no official record, nor is it taken into account in the estimate of the population to the middle of the year, which was 4,371,455.

During the year 1908 the number of deaths registered in Ireland was 76,891, equivalent to 1 in 57, or 17.6 per 1,000 of the population, estimated to the middle of the year. The death-rate (17.6) is 0.1 below that for the year 1907, and 0.2 under the average rate for the preceding ten years. The total number of deaths from all forms of tuberculous disease was 11,293, as against 11,679 registered in the year 1907, the former figure representing a death-rate from the disease of 258 deaths in every 100,000 of the population, and the latter a rate of 267 per 100,000 of the population.

For the four Provinces the recorded death-rates are as follows:—Connaught, 13.8; Munster, 16.1; Ulster, 18.1; and Leinster, 19.1 per 1,000 of the population, according to the Census of 1901.

On the subject of tuberculosis in Ireland, the Registrar-General says:—"It is my pleasing duty to have the honour of reporting to your Excellency the fact that the rate of mortality per 1,000 from all forms of tuberculosis declined during the year 1908 to 2.6, the corresponding figure for the three years 1905, 1906, and 1907 being 2.7. When the actual numbers are taken it appears that as compared with the mortality of the previous year there were 386 fewer victims to the ravages of the disease, which is a matter for much congratulation. A further satisfactory feature, moreover, is that the decline is observable in the pulmonary cases, which number 8,511, as compared with 8,828 in 1907. I earnestly trust that this may be the beginning of a gradual fall in the death-rate from this terrible malady, and that the magnificent anti-tuberculosis campaign inaugurated and carried on through the agency of the Women's National Health Association of Ireland—by Her Excellency the Countess of Aberdeen—has begun to tell on the mortality records of our island. The Tuberculosis Exhibitions held under the auspices of Her Excellency in almost all its large towns, and the tuberculosis vans which under her direction have travelled through many of the rural districts, have instructed the people as to the infectious nature of the disease, and the means of protecting themselves from its ravages, and evidences are not wanting that the lessons thus inculcated are bearing fruit, and that in many places there has been a material change for the better amongst our people in their habits and surroundings."

Proceeding to a comparison as to what is happening in connection with this dread disease in England, Wales, Scotland, and Ireland, the return states that in 1864 in England and Wales the rate was 3.3 per 1,000, and in the year 1907 it was 1.6 per 1,000. In Scotland in 1864 the rate was 3.6 per 1,000, and in 1907 it had fallen to 2.1 per 1,000; and in Ireland the rate, which in the first year of the period was 2.4 per 1,000, was 2.6 per 1,000 in the year 1908, having declined to this from the rate of 2.7 per 1,000, representing the mortality from tuberculous disease in Ireland in each of the years 1905, 1906, and 1907.

## CORRESPONDENCE.

FROM OUR SPECIAL CORRESPONDENTS  
ABROAD.

### FRANCE.

Paris, July 18th, 1909.

#### PURULENT OPHTHALMIA.

At a recent meeting of the Académie de Médecine, Dr. Motais communicated a series of cases of purulent

ophthalmia treated with invariable success by the following method:—

Irrigation of the eyes as often as necessary—that is to say, each time that a small quantity of pus appears between the lids—with a small plug of absorbent wool steeped in a solution of permanganate of potash (5 gr. to a quart).

The eyelids should be drawn apart as much as possible, but without the use of instruments, for fear of injuring the epithelium of the cornea.

In case the secretion tends to stick the eyelids together in drying, the edges are painted with an ointment of vaseline and iodoform (1—50).

Besides the constant application of the permanganate solution, 2 drops of a solution of protargol are instilled every six hours, and in severe cases every three hours:—

Protargol, 15 gr.

Water, 1 dr.

Ulceration of the cornea is no counter-indication to this strong solution; on the contrary, when present, it heals rapidly under its influence.

By this treatment, if followed methodically, the secretion diminishes from the first day. At the end of the third or fourth day it has almost disappeared; the strength of the solution may be diminished by one-half, and continued until a complete cure is obtained.

The author concluded by suggesting that protargol should be substituted for the classical nitrate of silver, which can hardly be trusted to inexperienced hands, whereas protargol is at least just as active and absolutely inoffensive.

#### NEURALGIC AND MIGRAINE POWDERS.

Antipyretic and analgesic substances practically belong to three well-defined chemical groups:—

Antipyrin and its derivations;

The derivatives of aniline;

Quinine and its derivatives.

It is substances of these three groups, says Dr. Martinet, which, isolated or combined, form the basis of all the powders and wafers reputed as specifics for neuralgia or sick headache.

Antipyrin, produced by Knorr in 1884, is the most ancient and most celebrated of anti-neuralgic substances. Its action is powerful and regular, and merits all the success it has acquired. However, antipyrin has furnished other salts which can bear comparison with the original.

Such is pyramidon, which can frequently be substituted, and sometimes with advantage to antipyrin; such may also be the case of salpyrin, a combination of antipyrin with salicylic acid.

Aniline is a powerful antithermic, but cannot be used on account of its toxic properties; but its derivatives—acetanilid, exalgin, phenacetin, lactophenin, citrophen, salophen—have all taken their place in the modern pharmacopœia. The first two (acetanilid and exalgin) should be prescribed only in one or two-grain doses, as they are more or less toxic.

Quinine and its salts represent the last group of antipyretic and anti-neuralgic substances.

Besides the usual salts (sulphate, hydrochlorate, hydrobromide), the most interesting derivatives are: aristochin, euquinin, and quiniiform.

The two former possess the advantage of being exempt from the bitterness which renders the administration of quinine to children almost impossible; quiniiform, being very soluble, may be administered hypodermically.

The synergic association of the three groups can be realised as follows:—

Phenacetin, 5 gr.

Hydrochlorate of quinine, 5 gr.

Antipyrin, 10 gr.

For 1 wafer; recommended in grippe.

The following formulæ are much used for migraine:—

Caffein, 1 gr.

Hydroch. of quinine, 2 gr.

Salipyrin, 10 gr.

Or,

Citric acid, 1 gr.

Caffein, 2 gr.

Antipyrin, 15 gr.

Or,

Caffein, 1 gr.  
Phenacetin, 8 gr.  
Salipyrin, 8 gr.

The addition of citric acid favours gastric tolerance.

All these formulæ might, in any case, be transformed into effervescing powders by adding tartaric acid and bicarbonate of soda:—

Antipyrin, 15 gr.  
Bicarb. of soda, 1 dr.  
Tartaric acid, 30 gr.  
Citric acid, 20 gr.

For 1 effervescent powder.

The following works wonders in dental neuralgia:—

Hydrochl. of morphia, 1/5th gr.  
Bromide of potassium, 10 gr.  
Antipyrin, 10 gr.  
Citric acid, 40 gr.  
Tartaric acid, 40 gr.  
Bicarb. of soda, 1 dr.  
Lactose, 1 dr.

For 1 effervescent powder; 2 daily.

#### ATROPINE AND ASTHMA.

Nearly all cases of asthma, of no matter what origin—cardiac, renal, nervous, etc.—are rapidly relieved by a 1/4 of a milligramme (1/250th gr.) of atropine, given in the form of pill or granule twice a day. It acts like a charm, and is immensely superior to injections of morphine, which cannot be always employed.

#### GERMANY.

Berlin, July 18th, 1909.

At the Medical Society Hr. Ed. Meyer showed a patient for whom he, along with Borchardt, had operated for

#### CANCER OF THE LARYNX.

First, he made a laryngo fissure, but shortly afterwards had to perform total extirpation, whereby, however, the epiglottis was retained and used as a cover for the wound of the pharynx. The wound healed up to a small œsophageal fistula; an attempt made to close this some time afterwards failed. For some time, therefore, the patient wore a Gluck's œsophageal tube. Later on the edges of the fistula were freshened, and the wound united by sutures in stages; by this means the opening closed. Phonation was bad, but the patient, who was himself a medical man, objected to wearing an artificial larynx, and made out with writing and deaf and dumb signs. A second patient was a girl of 19, who had had tracheotomy performed for diphtheria nine years ago, and who up to only a short time ago had been unable to get on without a tube. The speaker saw a cicatrix in the larynx just below the vocal cords; he dilated the tracheotomy fistula upwards into the larynx, excised the cicatrix, and made the larynx permeable again. Phonation had remained bad, as the vocal cords had been destroyed by the diphtheria.

#### Discussion on

#### HR. ROTHSCHILD'S PAPER ON THE ÆTIOLOGY OF HYPERTROPHY OF THE PROSTATE.

Hr. Casper recognised no connection between gonorrhœa and prostatic hypertrophy, although the former was looked upon as the essential cause of the prostatitis. Stricture was the very special consequence of gonorrhœa, and this was scarcely ever seen in connection with hypertrophy of the prostate. In the histories of prostatics, also, gonorrhœa was not unfrequently absent. Pathologically the hypertrophy was to be looked upon as a fibroma, or in more rare cases an adenoma, whilst it was only in rare cases that it was a simple overgrowth of connective tissue. If these things were so, the conclusions drawn by the reader of the paper in regard to treatment fell to the ground.

Hr. Mankiewicz pointed out that inflammation generally led to contraction, and the hypertrophied prostate usually contained as good as no secretion. Hr. Manasse said that if the views of the reader of the paper were correct, round cell infiltrations must be everywhere met with in hypertrophy; but that was not the case. If prostatitis could cause hypertrophy the latter would be observed in young people, as prostatitis was a disease of youthful age.

Hr. Rothschild, in the face of all these objections, still maintained his ground, and supported his position by the aid of numerous authorities. Hr. Fritz Meyer followed with a contribution to the

#### SERUM TREATMENT OF DIPHTHERIA.

He had been trying to get to the bottom of the 12 to 15 per cent. of deaths that still remained, even with the most favourable diphtheria statistics, and to avoid them. He distinguished four kinds of cause of death: 1, acute cardiac death; 2, too late or insufficiently treated cases; 3, deaths during re-convalescence from paralysis of the heart, or other post-diphtheritic paralyses; 4, cases of post-diphtheritic cachexia.

Acute cardiac death was due to vasomotor paralysis; if a rabbit were poisoned with diphtheric toxin the blood pressure sank. If this effect had once taken place, death could not be prevented by the serum, whilst injection of the serum in time prevented the sinking. After manifold attempts, he had succeeded in reaching the hypertoxine by the timely intravenous injection of efficiently large doses of toxine. If these doses were given in time, death was averted. For human treatment he proposed in these hypertoxic cases, where acute cardiac weakness was threatening, to inject larger doses, or even inject them into the veins. Cardiac stimulants appeared to be quite useless in these cases; adrenaline alone appeared to be of any use. If an energetic effect was to be obtained with serum large doses must be given from the first, a commencement should be made with 4,000 units of antitoxine, and the day after as much more should be given, or even more if necessary. A very carefully prepared serum without carbolic acid should also be kept in readiness for injection into the veins if required. Myocarditic changes could be set up in animals by toxins, if they could be kept alive long enough, the onset of such myocarditic changes in man were guarded against by the uses of serum. Post-diphtheritic cachexia, degenerative changes of various organs, were sometimes set up in animals, and an enlarged dose of serum protected the animal against these changes.

The speaker was of opinion that such cases as were being lost by the ordinary use of serum might be saved by larger doses or by intravenous injection.

Hr. Eckert had collected 40 cases of death from the Heubner Klinik during the last 10 years, and only 10 of them received injections in time. In bad cases very large doses had been given, and now and then injections had been given intravenously, without the small quantity of carbolic contained in them doing any harm. Assistance was necessary for this, however, where this could not be had the injections were made into the muscles. If toxic symptoms appeared during the course of the disease, large doses should be given afresh. He had also seen good from the subcutaneous employment of adrenalin, the only injurious result from the use of it was a transient glycosuria occasionally.

Hr. Ritter objected to excessive doses such as 40,000 units.

Hr. Heubner considered it an advance that we not only sought to bind the poison, as we did formerly, before it had attacked the organs, but that even when it had we tried to overcome it by correspondingly large doses.

#### AUSTRIA.

Vienna, July 18th, 1909.

#### HYPOPHYSIN.

HOCHWART and Frölich have been experimenting with the pituitary body, and gave the members of the Gesellschaft at the last meeting the benefit of their results. They find that hypophysin acts principally on the sympathetic (partially) and the "autonomy" nerve system; the latter is exemplified in the "nervus pelvicius." This extract was injected into cats, dogs, and guinea-pigs, with much the same results—viz., stimulating the bladder to contraction and irritating the automatic nerves, the nervus pelvicius, which was highly sensitive to the Faradic current after injection; the uterus in the female was also hyperæsthetic. Hypogastric nerves (sympathetic system) were not influenced by the injection. Repeated in-

jections, however, become gradually weaker in their action, but no alteration takes place in the blood pressure. The hypophysis does not act on the salivary glands, the vagus, nor the "nervus erigens," but the pupil is slightly contracted by it. Thus hypophysis acts differently to adrenalin, the latter being a stimulator of the sympathetic system, the former only of a few of the sympathetic and a few of the automatic nerves, particularly in the abdomen.

When disease commences or is induced in the hypophysis cerebri from before backwards, "dysgenitalismus" is the result. We can also have great disturbance in the bladder by tumours or enlargement of the hypophysis cerebri without having acromegalia present, which is not an uncommon occurrence, probably due to the loss of hypophysial secretion.

Hypophysis is non-poisonous, and may be freely used for clinical purposes in stimulating the uterus and bladder.

Pál said he now perceived that hypophysis was not a simple body, but a compound or complex one. According to Schaffer, this extract raised the blood-pressure, but Hochwart and Fröhlich tell us that it does not affect the circulation, but has a tendency to lower it. This may be due to the latter's observation that it acts on both the automatic and sympathetic nerves.

Tandler thought the infundibular part of the hypophysis cerebri was more cerebral than glandular, and, in operating for tumours, this part should be left and only the glandular part removed, which is probably the real part that aggravates the acromegalia.

Falta said he had injected hypophysis into a few patients, and certainly obtained a distinct diuretic result, the quantity of urine rising from 100 centigrammes to 150. The infundibular part, he found, had a stimulating action on the metamorphosis of the tissue.

Biedl believed that the infundibular portion of the hypophysis had a special function peculiar to itself, notwithstanding its origin in the nerve system. We have a similar analogy with the central nerve system in the medulla of the supra-renal body. Again, there are many substances enter the blood that produce pupillary dilatation and are not specifics. There is certainly a difference between hypophysis and adrenalin, though both act similarly with alkaline methylamine.

#### OPERABLE CARCINOMA.

Zinner next raised the question which has often been discussed: When should we operate? With the example of 123 cases before him of operations in the bowel for carcinoma, he could only refer to the percentage of success as an answer. Four of the 123 were squamous epithelioma and 119 cylindrical carcinoma. The average results were best in the latter, particularly amongst the gelatinous adenomatous cancer, of which there were 41 per cent.; in the non-gelatinous adenoma there were 24 per cent. of recoveries. The gelatinous carcinoma will heal well, but has a peculiar proclivity of forming metastases. Every form of the cylindrical cell carcinoma will heal, but the really malignant should be left untouched.

Hochenegg remarked that every carcinoma with these simple anatomical properties will heal and recover, but the real diagnostic sign of an operable case was its motility and glandular infection.

Rosthom said that from 100 uterine operations for cancer he had come to the conclusion that the histological constituents were of no value to determine an operation. Small carcinomata, in consequence of their extensive infiltration of the lymphatics, have little chance of healing, while large growths, with the same anatomical consistency, recover quickly.

### FROM OUR SPECIAL CORRESPONDENTS AT HOME.

#### SCOTLAND.

EDINBURGH UNIVERSITY—CHAIR OF SURGERY.—The following are applicants for the Professorship of Systematic Surgery in the University of Edinburgh, rendered vacant by the resignation of Mr. Chiene:—

Charles W. Cathcart, M.B., F.R.C.S.Eng. and Edin., John Wheeler Dowden, M.B., F.R.C.S.E., Alex. Miles, M.B., F.R.C.S.E., James W. B. Hodsdon, M.D., F.R.C.S.E., Henry Alexis Thomson, M.D., F.R.C.S.E., David Wallace, C.M.G., M.B., F.R.C.S.E. The Curators meet on the 21st inst. (to-day) for the purpose of making the appointment.

EDINBURGH SICK CHILDREN'S HOSPITAL CONVALESCENT HOME.—The newly erected Convalescent Home in connection with the Sick Children's Hospital, situated at Muirfield, Gullane, was formally opened by Mr. James Clark, Chairman of the Directors, on July 17th. The Convalescent Home is mainly due to the generosity of the late Miss Meikleham, who left Muirfield House and the residue of her estate for the purpose. The original intention of the directors was to reconstruct the old mansion house, but eventually it was decided to pull it down and erect a new building on the site. The Convalescent Home, from plans by Mr. R. S. Lorimer, R.I.B.A., consists of a centre block of administrative buildings, two storeys high, with east and west single-storey dormitories connected by a glazed verandah, which may be utilised as a covered playground for the children. Accommodation for 24 cots is provided. After Mr. Clark had explained the scope of the Convalescent Home, he handed a gold key to Mrs. Maconochie, who then formally opened the building. Mr. H. J. Stiles, surgeon to the hospital, in proposing a vote of thanks to Mr. Clark, expressed the indebtedness of the staff to the directors for providing an additional means of cure of tuberculosis of bones and joints, and so diminishing the number of crippled children in the community.

PUBLIC HEALTH OF EDINBURGH.—In his first annual report on the public health of the City of Edinburgh, Dr. Williamson, the new Medical Officer, has had the good fortune to chance upon a record year, for the mortality he has to report—13.37 per 1,000—is the lowest in the annals of the town. The special efforts which have been initiated to reduce the infant death rate have been attended with a considerable measure of success; the first step was the adoption of the Notification of Births Act, and the second the appointment of a lady health visitor, assisted by a number of voluntary health visitors. It is as yet too early to deal in detail with the work of these ladies, but the outstanding fact remains that during the year under review the infantile mortality was at the rate of 114 per 1,000 births, compared with 121 per 1,000 in 1907, and 147 per 1,000 ten years ago. This implies that 257 children reached their first birthday in excess of the number who would have done so if the infantile death-rate of ten years ago still prevailed. The noteworthy point in connection with zymotic diseases are, first, that on account of the prevalence of scarlet fever, the notifications were slightly above the average; second, that the case mortality is lower than ever before—.69 per 1,000, as compared with .88 in 1907, and 1.01, the average for the past few years; and third, that typhoid fever is vanishing. Only 55 cases occurred during the year as compared with the previous average of 178. This is undoubtedly a result of the improved sanitary administration of the city, and justifies the hope that enteric, like typhus, may some day be a thing of the past.

The compulsory notification of phthisis is being carried out in a harmonious manner as regards the medical profession and the citizens generally. Dr. Williamson urges the need for some arrangement being perfected between the Victoria Hospital and the local authority in order that the information at the disposal of the former may be transmitted to the Medical Officer of Health. In the usual statistical tables a great deal of information is given. The birth-rate in Edinburgh was only 21.4 per 1,000, the only other large towns giving so low a figure being Bradford (20.2) and Brighton (21.3). The decline in the infantile mortality, referred to above, is part of a general decline which has been going on for many years, but when different parts of the town are compared it is seen that there is still much room for betterment. Thus in one area in St. Giles' Ward the mortality is 232 per 1,000, in the Cowgate 344, in the Grassmarket and West Port 214, in Greenside 184, in the

Lawnmarket 170. Turning to the principal causes of deaths, it is shown that tuberculosis accounted for 13 per cent. of all deaths, and cancer for about 7 per cent. There is a decrease in the deaths ascribed to alcoholism, but influenza and diarrhoea account for a somewhat heavier mortality than in 1907. There were 32 suicides during the year.

**GLASGOW UNIVERSITY—RETIREMENT OF PROFESSORS.**—Principal MacAlister presided over the summer graduation ceremonial on July 13th, and after the degrees had been conferred, he called in Professor Cleland to say a few valedictory words on the occasion of his retirement. Professor Cleland said that nobility of purpose was the most effective stimulant to study as well as to the performance of duty at the bedside, and it ennobled the whole acquisition of knowledge of any description. Even vivisection—that bugbear of unbalanced minds and of many who would be thought kind-hearted, and thought themselves so—even vivisection was made noble by the amount of suffering it prevented, and which could be prevented by no other means. He had often noticed that his friends who were obliged to resort to vivisection had the most praiseworthy fondness not only for man, but also for bird and beast.

The Principal said he could not dismiss the assembly without voicing, in the name of the whole university, the debt they owed Professor Jack and Professor Cleland for what they had been and what they had done for Glasgow during the last 30 years. He wished them in their happy retirement the rest and enjoyment they had so admirably earned.

### BELFAST.

**ANNUAL MEETING OF THE BRITISH MEDICAL ASSOCIATION.**—The Seventy-seventh Annual Meeting of this Association will be held here on July 23rd, 24th, 26th, 27th, 28th, 29th and 30th next, under the presidency of Sir William Whitla, Professor of Materia Medica and Therapeutics, Queen's College, Belfast. Fifteen Scientific Sections have been arranged and will meet daily from Wednesday to Friday in the Queen's College at 10 a.m., viz.:—Anatomy and Physiology, Dermatology and Electro-Therapeutics, Hæmatology and Vaccine Therapy, Diseases of Children, Navy, Army and Ambulance, Hygiene and Public Health, Laryngology, Otology and Rhinology, Medicine, Obstetrics and Gynæcology, Ophthalmology, Pathology, Pharmacology and Therapeutics, Psychological Medicine, Surgery, and Tropical Medicine. The programmes throughout promise particularly interesting discussion owing to the large attendance of men of eminence from foreign countries and various parts of the British Empire. On Tuesday, at 2.30, Sir William Whitla will be inducted to the Presidential Chair; while at 8.30 p.m., he will deliver his address in the Assembly Hall. On Wednesday, July 28th, at 12.30 p.m., Dr. R. W. Philip, F.R.C.P.E., of Edinburgh, will deliver an address on Medicine in the Library, Queen's College. On Thursday, July 29th, at 12.30 p.m., the address on Surgery will be delivered in the Library, Queen's College, by Mr. Edward James Barker, F.R.C.S. On Friday, July 30th, at 12.30 p.m., Sir John W. Byers, M.D., will deliver an address on Obstetrics in the Library, Queen's College. At 8 p.m. a popular lecture will be delivered by Dr. J. A. Macdonald. At 8.30 p.m., reception by the President and local members of the Ulster Branch in the Botanic Gardens. The annual dinner takes place on Wednesday, July 28th, and the same evening a ladies' reception will be given by the local members in the Grand Opera House, when plays will be performed by the Ulster Literary Theatre. Their Excellencies the Lord Lieutenant and the Countess of Aberdeen will visit Belfast during the meeting, and have accepted invitations to attend the President's address and various social functions. At the ladies' reception, on Wednesday evening, the Countess has kindly promised to welcome the visitors to Ireland.

**THE TUBERCULOSIS ACT IN BELFAST.**—At a recent meeting of the Public Health Committee of the Corporation, the Medical Officer of Health submitted a report upon this Act. He stated that he was exceed-

ingly doubtful of compulsory notification being of much utility, as the Act did not secure for the local executive sufficient power to make it effective. The prescribed forms of tuberculosis were too limited, and there were too many restrictions. Last year voluntary notification and the information obtained through the dispensaries resulted in the discovery of 1,213 cases, all of which were visited, often more than once. One part of the Act the Medical Officer welcomes specially, and that is Part III., which gives power of control over milk supplies. Only about a third of the milk used in the city is at present subject to proper inspection and control, that coming by rail from distant villages not being so subject. It is to be regretted that under the Milk and Dairies Bill now before Parliament this power would be greatly weakened and curtailed, and, acting on the advice of the Medical Officer, the Public Health Committee have agreed to make representations to the President of the Local Government Board of England to withdraw this repealing clause from the Bill. The question as to the adoption of Part I. of the Tuberculosis Act in Belfast is still under discussion.

## LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

### NORMYL TREATMENT.

*To the Editor of THE MEDICAL PRESS AND CIRCULAR.*

SIR,—My attention has to-day been called to the letter in your issue of June 30th, by a self-styled "Medical Temperance Reformer" which is not very complimentary to the Normyl Treatment Association, of which I am the Chairman.

The claims of the Normyl treatment, which are not advertised in the ordinary way, have been so often explained in public that I am a little surprised at your correspondent's ignorance, but I suppose it ought to be corrected.

No member of the Association has the slightest pecuniary interest in the sale of the Normyl treatment, and the only reason which makes me and the other members of my Committee enthusiastic in recommending it is, that we have daily and hourly proofs of its efficacy.

The 150 doctors who are customers of ours have no more reason for concealing their names or being ashamed of their proceedings than the hundreds of others who recommend patent medicines to their patients every day. Many of them have been kind enough not only to give us the use of their names, but also to speak on public platforms on behalf of the Normyl treatment. They don't pretend that it will work a miracle, nor does any member of my committee, but they confidently assure me that it is the best remedy which has yet come within their experience, and that is exactly what I feel about it, and all that I have ever said on the subject.

I can answer personally for the complete cure of many police court cases, which are generally considered the most hopeless, and if your correspondent has the slightest desire to know the truth, he will find at our office, in 91 Victoria Street, S.W., the best possible evidence that thousands have been cured by the treatment who but for it might still be enduring the utmost misery.

Your correspondent is at liberty to have the Normyl preparation analysed, as we have had on many occasions, but he will still find that there is one secret ingredient in the mixture, and if he will be kind enough to pay for it we shall be only too pleased to make it known. Unfortunately, the inventor wants something like £20,000 for the discovery, and this is too much for our purse.

We have tried to have a public inquiry by the Home Office or the Local Government Board, but although Parliament did sanction such an inquiry, the Departmental Committee decided that the question of remedial treatments for drunkenness was too intricate, and the research would be too expensive for them to undertake.

Secrecy is no doubt frequently the badge of fraud, but by no means always, and the most hopeless victims of illusion are often those who cannot accept a good thing which seems to contradict their theory, and are unwilling to credit those who differ from them with the same honesty as that with which they wish themselves to be credited.

I am, Sir, yours truly,

CECIL CHAPMAN.

The Athenæum, July 12th, 1909.

#### THE ANTI-VIVISECTION CONGRESS.

To the Editor of the MEDICAL PRESS AND CIRCULAR.

SIR,—Among the crowd of fanatics who, during the past week, have amused themselves in a wild orgy of mendacity and abuse, not a single name of any weight in science, literature, art, politics, or religion, with the exception I am about to mention, has appeared; and there need be no fear that their demonstrations will lead to the prevention of a single necessary physiological experiment, or do anything to check the beneficent efforts of scientific explorers. It seems to me, however, that notice should be taken of the appearance on the scene of the Venerable Archdeacon Wilberforce, Chaplain to the Speaker, who, at any rate, holds a distinguished position in the Church of England. He preached on Sunday morning at St. John's, Westminster, to the Congress, and a report of his sermon appears in the *Times* of to-day, July 12th. In that sermon he stated that there were no greater cruelties perpetrated in the world than those done in some of the physiological laboratories—he said "some" because he "gratefully acknowledged that there were some exceptions in the English laboratories." If Archdeacon Wilberforce knows of a single laboratory in which cruelty is perpetrated, it is his duty to name it. He does not name one, well knowing that he might be compelled to substantiate his statement in a court of law. It is a gross and cowardly libel, not less atrocious because uttered by a minister of the Gospel from the pulpit of a church of the English Establishment. Whatever the effect of Archdeacon Wilberforce's utterances in other directions may be, there can be no doubt about the injury they must inflict upon true religion, and upon the Church that he professes to represent.

I am, Sir, your truly,

PHYSIOLOGIST.

July 12th, 1909.

#### THE PRESS AND QUACK ADVERTISEMENTS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In an editorial note to-day you once more comment upon the attitude of the newspaper Press with regard to quackery. Whatever be its significance as a sign of the times, there cannot be the least doubt about the demoralisation in one direction which now characterises many newspapers. These are showing themselves almost completely unscrupulous in their money-making methods. The editors take up the rôle of censors of private and political morality, whilst the proprietors augment their incomes by deliberately participating in crime, knowingly opening their pages to advertisements designed to entrap the simple, suffering public into hands where they will be maltreated and plundered. I enclose, as examples, two advertisements now appearing in one of the papers which stands in the very front rank of journalism. One puff, as you will see, occupies a whole column, and is composed and printed to imitate editorial matter. I ask you, Sir, whether there can be any doubt in the mind of any man of the world as to the character of this puff, and whether the proprietors, the managers, and the editors of this great paper must not be well aware of its nature and aim?

To the second smaller advertisement I would particularly beg attention. It emanates from a quack whose methods were exposed some time ago in the Law Courts. His advertisement had previously appeared for months in this same paper, and yet a leader denouncing him, and sympathising with his victim, was published after the trial. This paper has been distinguishing itself by the same conduct for

some years, and I have repeatedly called your attention to it. In this case we must suppose that the editor himself is unable to see the enormous fraudulent puffs that strike the eye of every other reader of his paper. This editor has also, as I have previously made known to you, published leaders exposing certain kinds of City swindlers, whilst huge puffs of these same gentry have been regularly appearing in his pages. Such conduct of many leading papers has led to the further demoralisation of the majority of inferior ones. These now show themselves willing to add their editorial endorsement to the false statements of any rogue prepared to pay the price; their columns are crowded with fraudulent puffs. The whole thing constitutes a gigantic scandal. It can be put an end to only by exposure through a Royal Commission such as I have so long advocated. It has been over and over again demonstrated, and can be again easily proved in public, that the coarser forms of medical quackery are not only fraudulent, but cruel and murderous, and that the system could not be kept up without the help of newspapers suborned to promote a nefarious traffic with the nature of which they are fully acquainted.

I am, Sir, yours truly,

HENRY SEWILL.

The Old Rosery, Redhill, July 14th, 1909.

#### OBITUARY.

ARCHIBALD DONALD, M.D.GLASG., M.R.C.S., L.R.C.P.

WE regret to record the death of Dr. Archibald Donald, which took place at Penang, Straits Settlements, on June 14th last. Dr. A. Donald was a son of the late Dr. J. T. Donald, and succeeded his father as medical officer of health for the burgh. He resigned the medical officership in order to devote himself to the special study of surgery, and after spending about two years in London he returned to Paisley, and resumed practice in partnership with his brother, Hugh C. Donald, F.R.C.S.E. Four years ago he left Paisley to join a younger brother who was a medical practitioner at Penang, and liking the place, he remained there. Heart failure, following a chill, was the cause of death. Dr. Archibald whilst in Paisley was one of the leading medical men in the town, and in addition to being an M.D. of Glasgow he was an M.R.C.S. (England) and an L.R.C.P. of London. He was only 43 years of age, and was unmarried.

RAYNER WINTERBOTHAM BATTEN, J.P., M.D.LOND., F.R.C.P.

WE regret to announce that the death took place at Gloucester, on July 15th, of Dr. Rayner W. Batten, J.P., at the age of 74. Dr. Batten was appointed physician to the Gloucester Infirmary in 1867, which post he held until 1899, when, upon resigning, he was appointed consulting physician, a position he retained until the time of his death. As physician he became an ex-officio member of the General Committee of the Infirmary, and after his resignation he was elected a member in 1901. Other positions which Dr. Batten had held were those of consulting physician to the Gloucester Dispensary, and also to the Berkeley Cottage Hospital.

WILLIAM BROWN, M.R.C.S.ENG., L.R.C.P.ED.

WE regret to announce the death of Mr. William Brown, Consulting Medical Officer of Health for the City of Carlisle, who died at the Hydropathic Establishment, Craiglockhart, near Edinburgh. Professionally educated at Edinburgh University and the Royal College of Surgeons, Edinburgh, Mr. Brown was admitted a member of the Royal College of Surgeons, England, in 1872, and a licentiate of the Royal College of Physicians, Edinburgh, the following year. He was subsequently elected a Fellow of the Royal College of Surgeons, Edinburgh. He was the author of a long series of medical reports on the health of Carlisle, and had made other contributions to medical literature.

## SPECIAL ARTICLES.

### THE HENRY PHIPPS INSTITUTE FOR THE STUDY, TREATMENT AND PREVENTION OF TUBERCULOSIS.

WE have watched with interest the progress of the Henry Phipps Institute since its inauguration in 1903.

It began as an experiment amidst many difficulties; now it may be said that it has taken its place amongst the great institutions of the world engaged in the fight against tuberculosis.

With each passing year system is becoming established, and the methods of examination and classification are becoming more accurate, consequently the information gleaned is more precise and useful. In the volumes before us (third and fourth annual reports), the clinical and sociological reports of Dr. Lawrence F. Flick are of most general interest. Aliens and children of foreign-born parentage form a great portion of the population of Philadelphia, which therefore offers a useful field for investigating the incidence of tuberculosis amongst the various races comprised therein.

There are many fallacies which cannot be avoided in drawing conclusions from the figures given in the reports, still they provide us with much material for thought and speculation, and each volume which issues from the Institute brings us a little nearer to accuracy in results.

Incidentally we are impressed with the huge problem which confronts the Government of the United States in dealing with its alien population. Foreign-born citizens bring nearly one-half the burden of the crusade against tuberculosis in which the Institute is engaged, while about 32 per cent. only of all tuberculous patients treated were of native ancestry one generation back.

The foreign-born patients mostly came from the following countries—from the highest number down:—Russia, Ireland, Germany, Italy, England, Austria, Hungary, Poland. Scotland has fallen out of the list of countries worthy of mention in this regard. No figures are given showing the proportion which each nationality contributes to the total population of the city.

In the study of these reports one is more than ever impressed with the fact that tuberculosis must be fought in the homes of the people. Sanatoriums as a factor in treatment are essential, but with a view to the prevention of the disease the supervision of the cases in their homes by qualified, tactful health visitors is the surest method of checking the spread of infection and of obtaining the earliest information of cases which arise amongst contacts.

In this direction the Henry Phipps Institute may be said to be working on lines very similar to those adopted by Dr. Philip in Edinburgh.

## REVIEWS OF BOOKS.

### PULMONARY TUBERCULOSIS. (a)

THIS handsome volume is a noteworthy addition to the literature of tuberculosis. It is comprehensive and practical, and while it will be of interest to all classes in the profession of medicine, it will be of especial value to the general practitioner anxious to keep abreast of modern clinical methods and treatment. The work is divided into six parts, each of which is sub-divided into sections and chapters. This arrangement leads to some slight overlapping, but, on the whole, the continuity of the volume is well maintained. The arrangement of the parts is as follows:—Part I.—Etiology and Pathological Anatomy. Part II.—Symptomatology, and Course, Varieties, and Termination. Part III.—Physical Signs. Part IV.—Diagnosis and Prognosis. Part V.—Complications.

(a) "Pulmonary Tuberculosis and its Complications." By Sherman G. Binney, A.M., M.D., Professor of Medicine, Denver and Gross College of Medicine, Medical Department of the University of Denver, &c. Pp. 778, with plates and photographs. Philadelphia: W. B. Saunders Company. 1908.

### Part VI.—Prophylaxis: General Treatment and Specific Treatment.

The relation of human and bovine bacilli is discussed in the light of recent investigation, and the author urges that there should be "no abatement of the legislative, municipal, and individual measures to suppress the disease amongst domestic animals, and afford protection to the human race." We think that the facts adduced in the text would justify a stronger statement of the pressing need for the control of bovine tubercle by central authority.

"The Channel of Infection" and "The Influence of Race" are dealt with, and the gradual growth of knowledge during recent years, the result of careful and laborious research all over the world, is well exemplified in the pages devoted to the consideration of these subjects.

The last chapters deal with theories of immunity and personal observations upon the use of bacterial vaccines. The experiences of the use of vaccines during a period of a year and a half are given.

The book is well illustrated throughout. Some of the pictures in the chapters on "The Scope of the Sanatorium," and on "The Role of Climate in Treatment," might have been omitted. They show very little, and the volume would be quite large enough without them.

A word of praise must be given to the series of plates of pathological conditions, the work of Mr. Ira D. Cassidy, in which the colours are beautifully produced and wonderfully true.

A copious index renders the book convenient for purposes of reference.

### BACTERIOLOGY. (a)

The excellence of recent editions of well-known English text-books on bacteriology induces an almost hypercritical attitude on the part of a reviewer, so that he judges subsequent volumes with an exalted idea of what a book on the subject should be. Professor Jordan's book, however, is, as might be expected, admirable. It includes much valuable and thoroughly reliable information, and is rendered the more acceptable by the excellence of the illustrations. Not only are "our secret foes," to use a popular phraseology, thoroughly well described, but "our secret friends" come in for a bigger share of attention than they are usually accorded. Among the economic bacteria we may mention that those concerned in the "nitrogen cycle" are very fully discussed. We think that disinfection has scarcely received the consideration that it merits, but otherwise we regard the book as eminently satisfactory.

### LECTURES ON DISEASES OF CHILDREN. (b)

THIS work is a compilation in book form of a series of lectures delivered by the author at the London Hospital. It contains 24 lectures, five of which have been added since the first edition appeared, dealing with the common diseases of childhood. The book is eminently practical from cover to cover, and could only have been written by one who is in constant touch with the subject of which he is treating. We agree with him that the style is in places "rather colloquial in character"—in fact, we would go further and say very colloquial and very dogmatic. But these are, of course, the attributes of a good lecture. The book is, moreover, very readable—in fact, so much so, that one catches oneself accepting as true conclusions which, on second thoughts, prove to be very debatable. It is in no sense a text-book, and often touches only the fringe of the subject, but it embodies thoroughly good teaching as far as it goes. It should continue to be of great help as an introduction to the study of children's diseases, for each chapter contains valuable matter, clearly stated. The numerous illustrations are nearly all reproductions of photographs of the author's cases, and are particularly good.

(a) "A Text-Book of General Bacteriology." By Edwin O. Jordan, Ph.D., Professor of Bacteriology in the University of Chicago and in Rush Medical College. Pp. 557, with 163 illustrations. Philadelphia: W. B. Saunders Company. 1908.

(b) "Lectures on Diseases of Children." By Robert Hutchison, M.D., F.R.C.P. Second Edition. London: Edwin Arnold. 1909.

## SUMMARY OF RECENT MEDICAL LITERATURE, ENGLISH AND FOREIGN.

*Specially compiled for THE MEDICAL PRESS AND CIRCULAR.*

**Ascites in Cirrhosis of the Liver Cured by Tapping.**—Patterson (*Amer. Journ. Med. Sciences*, May, 1909) records one of those very rare cases in which repeated tapping appears to have exercised a curative effect on ascites due to pure cirrhosis of the liver. Ever since the publication in 1893 of Hale White's paper on the subject, it has been recognised that the supervention of ascites is to be looked on as a terminal symptom in cirrhosis of the liver. Cases of cure of the ascites have been recorded, but they are of great rarity. Patterson's patient, a male, æt. 58, came under observation on October 9th, 1907, giving a history that six months previously he had noticed some swelling of his feet, and two months later enlargement of his abdomen. He had been drinking heavily for some time. Within a month the abdomen became so large that paracentesis became necessary, and 5½ gallons of fluid were withdrawn. A month later a second tapping was necessary, and 4½ gallons were removed. During the following four months the patient was tapped some six times, large quantities of fluid being withdrawn each time. Within a year the patient felt perfectly well, and had returned to work. He had grown fat, and was very active, and though he had returned to his excessive drinking, there were no signs of fluid in the abdomen. On March 17th, 1909, the patient died, having had symptoms of intestinal obstruction for one week, probably due to the strangulation of an umbilical hernia. On post-mortem examination about a quart of fluid was found in the peritoneal cavity, probably due to the condition from which he died. "The transverse mesocolon was adherent to the abdominal wall from the ensiform cartilage to the ninth right cartilage, and to the liver below and to the right of that point. The adhesions were not dense, nor highly vascularised. The liver was adherent to the diaphragm by a few readily broken adhesions, was greatly diminished in size, and showed the lesions of advanced cirrhosis. There was no perihepatitis. The peritoneum, as far as could be seen, showed no evidence of acute or chronic inflammation." K.

**The Relation of Gout to Granular Kidney and Lead Poisoning.**—West (*Practitioner*, July, 1909), though admitting that there often exists a close association between these conditions, doubts that there exists any causal relationship. Granular kidney is a fairly common disease, but it is by no means necessarily associated with either gout or lead poisoning. When it is, it is possible that, as a result of the renal inadequacy, the elimination, in the one case of the lead, and in the other of the uric acid, may be interfered with. Both gout and lead may each produce chronic changes in the kidney, but neither causes granular kidney. The presence, however, of granular kidney greatly increases the liability of the patient to gout, on the one hand, and to lead poisoning on the other, or to both together, and in each affection alike greatly increases the gravity and risk. K.

**Pulmonary Regurgitation.**—Drummond (*Med. Chronicle*, June, 1909) records a case of this very rare condition. The patient, a man, æt. 47, was admitted to hospital complaining of vertigo and headaches, shortness of breath on exertion, and pain referred to the precordial region. On examination the area of cardiac dulness extended well to the right of the sternum, where an impulse could be seen and felt. The left apex beat was in the sixth interspace, an inch and a half outside the mammary line. The veins of the neck were prominent, and presented a well-marked diastolic impulse. Loud "to and fro" murmurs could be heard at the base of the heart. The diastolic murmur was conducted down the left border of the sternum, but was well heard also at the right border. This

murmur appeared to replace completely the second sound at the base of the heart. Over the carotid artery blowing systolic and diastolic murmurs could be heard, but no second sound. The patient died about five weeks after admission to hospital. At the post-mortem examination the following changes were found:—"Both ventricles were greatly dilated, but the right particularly, the muscular wall of which was  $\frac{3}{4}$  of an inch in thickness. The edges of the aortic valve were thick and rounded, and the ascending aorta was expanded into a fusiform dilatation, whilst the inner coat of the vessel was patchy and scabrous, the result, apparently, of syphilitic sclerotic mischief. When tested with water, the pulmonary valves were found to leak. They were thin and membranous except at the adjacent edges of the left anterior and posterior cusps, which were united by a short fibrous band. They were also adherent for a short distance to the wall of the pulmonary artery close to the point at which they meet." K.

**The Modern Treatment of Fractures.**—Lucas-Championnière (*Brit. Med. Journ.*, June 12th, 1909) states that he has made mobilisation a leading principle in the treatment of fractures, and the success of the treatment has been due to very numerous clinical observations which have demonstrated the truth of the principle. The author considers that mobilisation to a great extent replaces the necessity of immediate suture of bones, and is certain that the more the method of mobilisation is developed, the fewer will be the occasions in which immediate suture will be performed. He has never had occasion to suture a recent fractured olecranon, because perfect recovery is obtained within a fortnight without operation, when properly treated by his method. Radiography has shown that, in spite of faulty position, and in spite of a certain degree of persistent over-riding, the function of a limb again becomes perfect. The object in treatment must not, therefore, be ideal juxtaposition. Every movement which is not injurious, by reason of its amplitude favours repair of bones, and is not less necessary to the vitality of the joints, muscles, ligaments, and tendons. Massage affords the best form of movement, but all such treatment should relieve and not cause pain. The reduction of a fracture is only a relative necessity, and in a large number of cases the manœuvre of reduction is useless. After massage the fracture is either spontaneously reduced, as in the case of the olecranon, or is very easy to maintain reduced, as in the case of the clavicle or malleolus. Massage should be used sparingly in children to avoid excessive callus formation. In general mobilisation from the beginning, within the first twenty-four to forty-eight hours, is of capital importance, and passive or induced movements are the best in the commencement. Active or spontaneous movements ought to be measured and directed by the surgeon, as by the author's method of treatment pain caused by movement disappears from the beginning, and therefore does not limit the untimely action of voluntary movement. The pain experienced and the degree of sensitiveness of the callus are the best guides in directing and in permitting movements by the patient. S.

**A Case of Volkman's Ischæmic Paralysis of both Forearms.**—Coullie (*Indian Med. Gaz.*, April, 1909) reports that a boy of 13 was brought to hospital suffering from the above condition. Six weeks previously he had fallen from a tree, and fractured both bones of either forearm about the middle of the shaft. Soon after the accident the arms were put in bamboo splints by the hospital assistant of a native state. The

splints were not disturbed for three weeks, and were then removed, owing to the occurrence of suppuration beneath them. The fractures had united, but the skin had necrosed in two places on either forearm. Under treatment the sores healed, but both arms presented a typical picture of Volkmann's ischæmic paralysis. The muscles were wasted. The finger-nails were poorly nourished and round, and some of them ulcerated. The wrist and fingers were semi-flexed, and prehensile power was feeble. The hand had a claw-like appearance, the extension of the fingers being prevented by shortness of the flexor tendons. Operation was advised, but refused by the parents. S.

**Adeno-Sarcoma in the Newly-born.**—De Villiers (*Transvaal Med. Journ.*, March, 1909) reports a case of tumour in the right parotid region which was present at birth, and had attained the size of a pigeon's egg in ten days. When the child was twenty-eight days old the writer was partially successful in removing the growth. The tumour was black in colour, and very friable. A similar dark, hard lump was found between the shoulder and the elbow. One month later the tumour had recurred. It had then spread so much that it nearly closed the right eye, greatly interfered with deglutition, and the mouth could hardly be opened. Microscopic examination showed the tumour to be an adeno-sarcoma. S.

**Septic Thrombosis (Puerperal) of the Pelvic Vessels.**—Bell (*Journ. of Obst. and Gyn. Brit. Emp.*, XV., 6) reports a case in which the thrombosed vessels were removed. On the twelfth day after confinement the patient's temperature was  $103.5^{\circ}$ , and pulse 130. Her appearance was bad; she looked very yellow, and seemed drowsy; she could, however, answer all questions. On examination there was no free fluid to be detected in the abdomen, nor any tenderness. The whole abdomen moved with respiration. The uterus was enlarged, and extended well above the pubes; it was not tender. *Per rectum*, some thickening high up on the right side could be felt; there were no thrombosed vessels felt in the lower part of the broad ligament. The cervix was dilated, and a gush of sanguineo-purulent fluid came from the uterine cavity, which showed a Gram positive diplococcus, but was sterile on culture, probably owing to lysol douche given three days previously. The patient's condition improved next day, but on the 14th relapsed, and on the 15th the temperature was  $104^{\circ}$ , pulse very rapid and weak. It was then decided to open the abdomen. The ovarian vessels on the right side were found thrombosed and forming a well-defined mass the size and shape of a banana. The peritoneum was split and the mass followed to the meso-colon; here it seemed to end, and the whole mass was ligated and excised, and the peritoneum closed. There was no thrombosis of the iliac veins. On the left side there was limited thrombosis of the ovarian vein. This was also excised. After the operation continuous saline was infused subcutaneously; the temperature fell to  $101^{\circ}$ , but, following a rigor, rose to  $106.6^{\circ}$ , when the patient died. Pathological report: Peritoneal fluid sterile; pus from right ovarian vein showed diplococci same as from uterus; sections of vessel further from uterus showed laminated thrombi, with a few leucocytes; left ovarian vein thrombosed, but seemed aseptic. Post-mortem: The right ovarian vein thrombosed to junction with vena cava; some veins thrombosed in uterine wall; interior of uterus apparently healthy. In conclusion, the writer says, it is not easy to make the diagnosis, and if it can be made, how far is it justifiable to say the patient will die if not operated upon? With regard to the latter, no one will deny that most of these cases do die, and therefore early operation must be aimed at, even though the patient is not dying at the time. He considers the delay owing to finding pus in the uterine cavity was prejudicial to this case. F.

THERE were 174 deaths from bubonic plague and thirty-six from cholera in Amoy during the fortnight ending on Monday.

## MEDICAL NEWS IN BRIEF.

### Medico-Legal Society.

At the annual dinner of this society, which was held last Thursday at the Holborn Restaurant, Mr. Justice Walton, President, in the chair, Sir William Collins proposed "The Law and Medicine." He said that no one could study the legislation of recent times without seeing what a large area of common territory there was in which law might be ancillary to medicine and medicine to law. The discussions which took place on the Prevention of Crimes Bill showed how necessary it was to have both legal and medical opinion in the House of Commons. The Master of the Rolls, in reply, acknowledged the constant indebtedness of Bench and Bar to the medical profession. Modern legislation, he said, tended more and more to wrap up medical and legal problems in single Acts of Parliament. Mr. H. T. Butlin (President of the Royal College of Surgeons) responded for the medical profession, and proposed prosperity to the society, which he described as one of the most important organisations formed in recent years. The President, in response, alluded to the wide possibilities of extension of their work and to the utility of their proceedings, not only to the members of the two professions but to the public at large.

### The Metropolitan Asylums Board—Annual Report.

DURING the financial year ended at Michaelmas, 1908, the net expenditure was £1,121,942, being a decrease of £13,841, as compared with the previous year, although the average daily number of inmates maintained was 485 in excess of the previous year.

Although the large number of fever and diphtheria patients under treatment in the hospitals during the spring of the year caused some apprehension, the maximum number under treatment (which was reached on November 30) was 1,856 below the highest number reached during 1907; in that year the number of patients surpassed all previous records, as many as 7,158 cases having been at one time under treatment in the board's fever hospitals. The total number of patients admitted into those hospitals during 1908 was 27,967, as compared with 32,169 in the previous year; 27,981 patients had been discharged from those institutions, and there had been 1,255 deaths, as compared with 1,405 in 1907. The mortality per cent. was:—Scarlet fever, 2.56; diphtheria, 9.73; enteric, 16.28; cerebro-spinal meningitis, 40.00; other diseases, 5.68. The average duration of residence of the patients in the hospitals was again on the increase. Not a single case of small-pox was admitted into the board's hospitals from the metropolis, though one case was received from Leyton. The cases of mistaken diagnosis (other diseases) admitted numbered 2,594, the percentage of error among cases certified as scarlet fever being 6.1, among diphtheria cases 22.2, and among enteric fever cases 39.1.

The total number of removals effected by the board's ambulances during the year was 59,870, of which number 1,291 were medical and surgical cases of a non-infectious character. The total number of journeys made by the ambulances was 34,260, the distances covered aggregating 421,594 miles. With the exception of the year 1907, the number of removals effected and the miles run was in each case greater than during any previous year of the board's history, and it was noted "that the record of entire freedom of the service from accident involving injury to any patient remains unbroken."

### The Travel and Sports Exhibition, London.

THE recent Travel, Sports, Pastimes and Tropical Exhibition at Olympia, London, was of a most interesting nature. The collection of hunting trophies was especially fine, and included heads, horns, stuffed beasts, birds, and so on, lent by General Baden-Powell, Major Radcliffe, and others. The Boy Scouts had a camp in one part of the building. Amongst other things was a fine show of aerial machines and models of motor boats and sporting tents. An attractive feature was an interesting exhibit by Messrs. Burroughes Wellcome. Many of their products are

particularly suited for the requirements of sportsmen and travellers, and there is little need to dwell upon the portability and other desirable qualities of tabloid drugs and compressed bandages and other appliances. One of this enterprising firm's most interesting exhibits was the collection of old and battered medicine chests from the Stanley and various other famous African expeditions. Travel-worn, yet efficient, they stand as silent witnesses to the masterful yet enterprising spirit which adapts modern science to the wants of the explorer of the remotest corners of the earth, and carries our most familiar remedies into the heart of savage countries.

#### International Congress on Alcoholism.

THE 12th International Congress on Alcoholism opened in London on the 19th inst. The International Permanent Committee met at 10 a.m. in Kensington Town Hall, and was joined later by the British executive. At 11.30, in the same place, the Congress held its first general meeting. The Dean of Hereford, Chairman of the Conveners' Committee, introduced Lord Weardale, the acting President, who delivered the address of welcome. At 5 p.m. an exhibition was opened in the north gallery; and at 9.30 the delegates, including the Crown Prince of Sweden, were received by Mr. Lewis Harcourt, M.P., First Commissioner of Works, on behalf of the Government.

The exhibition, which is open daily from 10 to 6 during the Congress, consists of two sections. The first is composed largely of literature, scientific and popular books, pamphlets, posters, anatomical and statistical diagrams, pictorial post-cards, and other publications used in the anti-alcohol campaigns of many countries, the regalia and banners of various temperance organisations, with challenge shields, badges, medals, and other paraphernalia used chiefly in temperance work among the young. The exhibitors in this section are very numerous, including not only organisations whose names are familiar in this country, but many in other lands. The other section of the exhibition is dietetic, and includes a model kitchen, a hand-cart of the Church of England Temperance Society, non-alcoholic wines, and other beverages.

#### The Sudlow Gold Medal.

MR. H. S. WELLCOME, principal of the well-known firm of Burroughs Wellcome and Co., was present at an interesting gathering last week of about fifteen hundred employees, in the grounds of the Dartford manufactory, when replicas in gold of the Sudlow Medal were awarded and presented by him to Dr. F. B. Power, director of the Wellcome Chemical research laboratories; Dr. Dale, director of the Wellcome physiological laboratories; Mr. J. C. Smith, and Mr. Linstead. A cordial note characterised the proceedings, as evidencing the mutual esteem held by employer and employed.

#### Royal College of Surgeons in Ireland—Prize List.

LIST of successful candidates for the Summer Session, 1909:—

Barker Anatomical Prize.—£26 5s., H. R. Tighe; Special Prize, £21, J. S. Pegum.

Carmichael Scholarship.—£15, J. T. Duncan.

Gold Medal in Operative Surgery.—Miss I. M. Clarke; Silver Medal, F. N. Harvey.

Stoney Memorial Gold Medal in Anatomy.—J. T. Duncan.

Practical Histology.—S. Griffin, First Prize (£2) and Medal; I. M. Swanepoel, Second Prize (£1) and Certificate.

Practical Chemistry.—N. A. Sheridan, First Prize (£2) and Medal; G. N. Smyth, Second Prize (£1) and Certificate.

Public Health and Forensic Medicine.—J. T. Duncan, First Prize (£2) and Medal; K. L. O'Sullivan, Second Prize (£1) and Certificate.

Materia Medica.—J. T. Duncan, First Prize (£2) and Medal; Vincent J. White, Second Prize (£1) and Certificate.

Biology.—J. D. Cherry and J. C. Sproule (equal), First Prize (£2) and Medal, each.

The lectures and practical courses of the Winter Session will commence October 15th.

#### Trinity College, Dublin.

THE following candidates passed the Preliminary Scientific Examination, Trinity Term, 1909:—

Physics and Chemistry.—Edward S. Johnson, William H. R. McCarter, Joseph S. English, William D. Pile, Blacker C. Powell, Hedley Boyers, James A. Small, Henry B. S. Dixon, Henry V. Fitzgerald, John G. Butt, Richard A. Stewart, Ernest Bantry-White, Albert W. D. Magee, William J. Merrick, George B. Hadden, Cedric C. Mecredy, William F. Evans, Reginald O. Smyth, Charles P. Kelly, David H. Hadden, Edward G. Fishe, Thomas J. Kelly, Michael Ryan, Herbert R. Ford.

Botany and Zoology.—Edward P. Vickery, David H. Hadden, Frederick G. Flood, John W. C. Stubbs, Frederick Harris, and William J. Merrick, passed on high marks; Theodore Allen; John G. Butt, Robert L. Vance, Dorothy E. Webb, Henry G. J. Rutherford, Eleanor Taylor, Trevor A. Lawder, Joseph C. A. McCalden, Joseph P. Quinn, James A. Small, Arthur N. Brady, John D. Oliver, Wm. F. Gibson, Francis A. Roddy, William E. Tyndall, Rupert C. Lowe, Reginald H. Jones, Archibald R. Toomey, Francis A. L'Eestange, William R. L. Waters, George A. Bridge, William D. Pile, Henry J. Brown, Edmund S. Hatte, Charles O'Reilly, George Buchanan, Henry C. D. Miller, Joseph A. Quin, Etienne J. Malherbe.

The following candidates passed the Intermediate Medical Examination (Part II.).—Arthur Chance, Maurice S. Moore, Patrick F. Munan, William Frier, Hugh E. Williams, Samuel A. Lane, Thomas W. E. Henry, Frederick Burke, Cecil Rutherford.

The following passed the Final Medical Examination (Part II.).—Midwifery: Beatrice M. Hamilton, Hilgard Müller, and Eric J. Powell, passed on high marks; Adams A. McConnell, Arthur C. Hallows, Marius A. Diemont, Benjamin A. Molyneux, David Duff, George E. Craig, William H. Hart, John W. Flood, Charles H. Denham.

The following candidates passed the Previous Dental Examination.—Physics and Chemistry: George G. Yeates. Materia Medica: Kenneth C. M'Naught Henry Kirk.

#### Conjoint Examinations in Ireland.

THE following candidates have passed the Second Professional Examination of the Royal College of Physicians and the Royal College of Surgeons, July, 1909:—

M. J. Hillery (with Honours), T. P. H. Roberts (with Honours), T. T. Buckley, N. S. Deane, H. J. Cotter, S. Griffin, R. Henry, W. H. Johnston, H. K. Kevin, R. Kenefick, T. Kennedy, J. Kearney, A. McGrath, F. J. McCarthy, M. Meehan, T. Mulcahy, J. C. O'Farrell, W. R. O'Keeffe, J. C. Ryan, I. M. Swanepoel, J. Walsh, V. J. White.

#### Institute of Chemistry.

In the June-July examinations, of 29 candidates who presented themselves for the intermediate examination the following 17 passed:—W. Caw, A. P. Clark, R. L. Collett, B.A. (Cantab.), W. Dickson, S. Elliott, R. H. Ellis, N. Evers, J. E. Hackford, A. D. Heywood, F. E. Laughton, J. R. Nicholls, W. M. Paulley, B.A. (Cantab.), G. C. Petrie, E. F. Pollock, S. Robertson, T. Schwarz, and J. A. L. Sutcliffe. One candidate presented himself for a general examination for the associateship, and passed—L. Knight, A.R.S.M. Six candidates presented themselves for the final associateship examination in the branch of mineral chemistry, and four passed:—H. L. Allen, B.Sc. (St. Andrews), R. H. Findlater, R. Gawler, B.Sc. (Leeds), and G. A. Smiley, B.Sc. (Lond.). In the branch of metallurgical chemistry, of five examined three passed:—A. Marcan, A. Marks, A.R.C.Sc. (Lond.), and A. W. Schultz, A.C.G.I. Of seven candidates who presented themselves in the branch of organic chemistry the following three passed:—R. Boyd, B.Sc. (Glas.), C. S. Garland, B.Sc. (Lond.), A.R.C.Sc. (Lond.), and J. Young. In the examination in the chemistry of food and drugs and of water, of nine who presented themselves five passed:—F. S. Aumonier, W. G. Carey, R. D. Carty, A.R.C.Sc.I., T. R. Greenough, B.A. (Cantab.), and C. E. Sage. One of the candidates, C. E. Sage, was examined for the fellowship.

## NOTICES TO CORRESPONDENTS, &c.

CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

### SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12. Messrs. Dawson and Sons are our special agents for Canada.

### ADVERTISEMENTS.

FOR ONE INSERTION:—Whole Page, 25; Half Page, 23 10s.; Quarter Page, 21 5s.; One-eighth, 19s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions, at 23 10s.; 26 at 23 3s.; 53 insertions at 23, and pro rata for smaller spaces.

Small announcements of Practices, Assistances, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

ORIGINAL ARTICLES OR LETTERS intended for publication should be written on one side of the paper only and must be authenticated with the name and address of the writer, not necessarily for publication but as evidence of identity.

CONTRIBUTORS are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland to the Dublin office, in order to save time in reforwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

M.O.H. (Scotland).—In the recently-issued report for the year 1908 by the Medical Officer of Health for the City of Liverpool, you will find some interesting photographs of country cowsheds whence tuberculous milk was sent into the city. Dr. Hope has done excellent work in the direction of supplying Liverpool with pure milk. His report is in many ways interesting, and will repay perusal by those engaged in public health work.

MR. F. S.—We think there exists no cause for anxiety on your part; on the contrary the annual statement you enclosed, seems to be a very straightforward, business-like announcement, which should encourage rather than adversely affect shareholders. The scare that Apollinaris was made and bottled in London, could only have been caused by rival interests, and may be dismissed as a disreputable trick from your mind.

H. B.—In laying down rat poison, it should be remembered that rats may carry the poisoned food far away from the original spot. Cases are on record, where dogs, cats, fowls, and even children have been poisoned by eating bacon and other baits that have been thus thrown in their way. The best plan is undoubtedly the Danyss or similar bacterial poison; but experience has shown it is not without risk, when used too near human dwellings.

R. F. NIBBETT (Surbiton).—The London Fever Hospital can be recommended under the circumstances you mention. It is intended specially for infectious patients who can pay a small fee. The Secretary's address, is Major W. Christie, Liverpool Road, London, N.

CIVIL SURGEON. (Lahore).—The lactate of mercury has been advocated as an antisyphilitic, on account of its safety and solubility. It is given in doses of one-fourth grain in fifteen minims of water, hypodermically, or one-fifth grain freely diluted by the mouth.

DR. H. J. C. (Brighton).—Any doubt as to the diagnosis should be rapidly cleared up by the administration of mercury. The only possible confusion, so far as can be judged from your letter, lies between an ulcerating syphilide and an epithelioma. The chief points in the former are the age of patient, tendency to heal in centre and spread peripherally, presence of other specific manifestations, together with rapid course and non-induration.

## Meetings of the Societies, Lectures, &c.

WEDNESDAY, JULY 21ST.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m.: Mr. Cecil H. Leat: Clinique (Surgical).

THURSDAY, JULY 22ND.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—4 p.m.: Sir Jonathan Hutchinson: Clinique (Surgical). 5.15 p.m.: Mr. Arthur Edmunds: "Chemical Antiseptics in Modern Surgery."

FRIDAY, JULY 23RD.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22 Chenies Street, W.C.).—College closes for Vacation.

CENTRAL LONDON THROAT AND EAR HOSPITAL (Gray's Inn Road, W.C.).—3.45 p.m.: Lecture: Mr. W. Wallis: Mouth and Teeth.

## Appointments.

CLARKE, N. D., Dental House Surgeon at Guy's Hospital.  
DORRIS, J. R., L.R.C.Lond., M.R.C.S., Assistant Medical Officer to the Royal Hamadryad Seamen's Hospital, Cardiff.  
EDWARDS, J. C., L.R.C.P. and S.Edin., District Medical Officer by the Merthyr Tydvil (Glamorganshire) Board of Guardians.

EMERSON, HERBERT BREE, L.R.C.P.Lond., M.R.C.S., District Medical Officer of Pershore (Worcestershire).  
GARRETT, R. R., L.R.C.P.Lond., M.R.C.S., Certifying Surgeon under the Factory and Workshop Act for the Bishopstoke District of the county of Hants.  
LITHGOW, J., M.D., C.M.Glasg., Certifying Surgeon under the Factory and Workshop Act for the Cleland District of the county of Lanark.  
MULCAHY, P., L.R.C.S.Irel., L.R.C.P.Edin., Certifying Surgeon under the Factory and Workshop Act for the Ballinamore District of the county of Leitrim.  
PIM, ARTHUR AUGUSTUS, F.R.C.S.Edin., L.R.C.P.Edin., L.F.P.S.Glasg., District Medical Officer by the Beaminster (Dorset) Board of Guardians.  
RICE, R. S., M.D.Irel., District Medical Officer by the Merthyr Tydvil (Glamorganshire) Board of Guardians.  
SMITH, THOMAS EDWARD, M.D., B.Ch.Dub., Medical Officer to Kelly College, Tavistock (Devon).  
SPAIN, H. G., Dental House Surgeon at Guy's Hospital.  
STUART, J. H. W., Dental House Surgeon at Guy's Hospital.  
WABNER, H. F., M.B., B.S.Lond., Certifying Surgeon under the Factory and Workshop Act for the Fakenham District of the county of Norfolk.  
WHITE, J., M.R.C.P.Irel., M.R.C.S.Irel., Certifying Surgeon under the Factory and Workshop Act for the Tullaroan District of the county of Kilkenny.  
WILLIAMS, L. A., M.D.Edin., D.P.H.Liverp., Medical Superintendent to the Bradford Educational Authority.

## Vacancies.

Lurgan Union.—Female Resident Medical Officer. Salary £80 per annum, furnished apartments and rations. Applications to James Calvert, Clerk of Union. (See advt.)  
Royal City of Dublin Hospital.—Anaesthetist Pathologist, x-Rayist and Dentist. Applications to the Hon. Sec., Medical Board. (See advt.)  
Tynemouth Victoria Jubilee Infirmary, Spring Gardens, North Shields.—House Surgeon. Salary £100 per annum, with rooms, board, etc. Applications to Mr. John W. Meadows, Secretary, 43, Howard Street, North Shields.  
Worcester County and City Asylum, Powick.—Third Assistant Medical Officer. Salary £140 per annum, all found. Applications to the Superintendent.  
St. George's Union, London.—Second Assistant Medical Officer. Salary £120 per annum, with board, residence, and washing. Applications to the Medical Superintendent.  
Derbyshire County Council.—Assistant Bacteriologist. Salary £150 a year. Applications to Sidney Barwise, County Medical Officer of Health, County Offices, Derby.  
Royal South Hants and Southampton Hospital.—House Physician. Salary £100 per annum, with rooms, board, and washing. Applications to T. A. Fisher-Hall, Secretary.  
Sunderland and Durham County Eye Infirmary, Sunderland.—House Surgeon. Salary £210 per annum. Applications to J. F. Potts, Secretary, Sunderland and Durham County Eye Infirmary, Stockton Road, Sunderland.  
Berks County Asylum, Wallingford.—Second Assistant Medical Officer. Salary £150 per annum, with board, furnished apartments, attendance, etc. Applications to Medical Superintendent.  
Cameron Hospital, West Hartlepool.—House Surgeon. Salary £100 per annum, with board, rooms, and laundry. Applications to J. G. Taylor, Secretary.  
Govan Parish School Board.—Principal Medical Officer. Salary £500 per annum. Applications to Mr. M. MacLeod, Clerk to the Board, 151 Bath Street, Glasgow.  
Glasgow District Mental Hospital.—Junior Assistant Medical Officer. Salary £125 per annum, with board, lodging, etc. Applications to Dr. Marr, Medical Superintendent.

## Births.

MCNABB.—On July 18th, the wife of Fleet-Surgeon D. McNabb, Royal Marine Depot, Walmer, of a son.  
NEWMAN.—On July 15th, at Windhill, Bishop's Stortford, the wife of J. C. Newman, F.R.C.S., of a daughter.  
SMITH.—On July 14th, at Cleveleys, 3 Redbourne Avenue, Church End, Finchley, the wife of Thomas Smith, M.R.C.S., L.R.C.P., of a son.  
WILSON.—On July 15th, at Ongar House, Chipping Ongar, the wife of Geoffrey R. Wilson, M.A., M.B., of a son.

## Marriages.

BIGGS—JEFFERISS.—On July 17th, at St. Mary's, Stanstead, Lewis Biggs, of "Greenfield," Meopham, to Alice Violet, second daughter of W. R. S. Jefferiss, M.D., 4 New Road Avenue, Chatham.  
MARTIN—DENNEY.—On July 14th, at St. John's, Bromley, by the Rev. Canon Barker, Robert Henry Martin, M.B., Sudbury, Harrow, son of S. Edgar Martin, M.A., M.D., Newry, Ireland, to Agnes, fourth daughter of M. J. Denney, Esq., Stoneleigh, Brounley, Kent.

## Deaths.

BROWN.—On July 14th, at the Edinburgh Hydropathic, Craiglockhart, William Brown, F.R.C.S.E., Consulting Medical Officer of Health for the city of Carlisle.  
HUTCHINSON.—On July 12th, at 7 Pittville Lawn, Cheltenham, Sarah Burns Hutchinson, widow of Berkeley Westropp Hutchinson, M.D., and grand-daughter of Robert Burns, aged 87 years.

# THE MEDICAL PRESS AND CIRCULAR.

"SALUS POPULI SUPREMA LEX."

VOL. CXXXIX.

WEDNESDAY, JULY 28, 1909.

No. 4.

## NOTES AND COMMENTS.

IN our correspondence columns **A Membership Diploma for the Association of Medical Diplomates of Scotch Colleges.** land, addressed to the Edinburgh College of Surgeons. It reminds the Council of that ancient Corporation of a petition addressed to them in 1905 praying them to take steps towards the institution of a diploma of membership, in addition to the existing qualifications of Licentiate and of Fellow, R.C.S.Ed. Their ground for this request is clear enough. The ordinary qualification of the English College is that of member, while that of the Scotch College is that of licentiate, and holders of the latter diploma are placed at a serious social and professional disadvantage when engaged in practice outside Scotland. Some years ago it was suggested in the columns of *THE MEDICAL PRESS AND CIRCULAR* (July 14th, 1905), that for the cumbrous conjoint qualification, L.R.C.S. & P.Ed. and L.F.P.S.Glasg., should be substituted the far more dignified M.R.C.S., L.R.C.P.Scot. Moreover, the title would be on all fours with the conjoint English qualification. If the Association of Medical Diplomates of Scotland prevail on the Council of the Edinburgh College and the Glasgow Faculty to adopt this common-sense suggestion, they should earn the lasting gratitude of the many holders of the Edinburgh and conjoint Scotch qualifications who are scattered throughout the world.

**If Not,  
Why Not?**

THE weight of argument appears to be all on the side of the Association. The College of Surgeons has been in existence for some four hundred years, and is now asked to take a step that would be not only extremely popular amongst its licentiates in all parts of the world, but would add considerably to its revenue, for it is to be presumed that fees would be charged for the new title. Nor would the suggested change throw any very great strain upon the constitution of the College. Charters are capable of amendment and extension without ruinous expenditure of time and money. We cannot help feeling that the College of Surgeons of Edinburgh, if unable to fall in line with the suggestion of a membership diploma, should at least state clearly the grounds for refusal. Another point is that the negotiations show incidentally the usefulness of a body like that of the Association of Scotch Medical Diplomates. It is only by the existence and the efforts of such an organisation that any collective expression of opinion and any united protection and advancement of interests can be secured. Reform is always a slow matter, and those who join a society of this nature have often to be content with the knowledge

that they are sowing good seed. Meanwhile, all holders of a Scotch diploma would do well to join the Association that has been founded in their interest. Another piece of extremely good work performed by the Association during the past year has been the bringing forward of the practical monopoly of the more important hospital appointments in England and Wales by holders of the higher English qualifications. Some strong meetings of protest were held in the spring in conjunction with the Irish Graduates' and Medical Schools Association.

**Injury by  
Shampoo—**

WHATEVER else the Workmen's Compensation Act, 1906, may or may not have done, it has made medical men pay far more attention to the ætiology of disease than they have ever done before. A light-hearted House of Commons finds it easy enough to pass a Bill for the compensation of workmen who sustain injury in their employment, and with that principle, we fancy, few will be found to quarrel; but when matters of fact come to be tested by the light of medical science, it can only be said that it is far easier to form theories than to establish them. The stuff that passes in law courts for evidence is emphatically not of the substance or weight which scientific men demand as proof when questions of significance in their own domain come up for decision. It may be a valuable habit, but from the point of view of airy theorists it is an awkward habit, which scientific men acquire of not considering a matter proved, so that further progress in the same line is warranted, unless the facts alleged in evidence are not compatible with any other reasonable theory. We can hardly, however, blame judges, whose notions of evidence consist in the assertions and counter-assertions before them, if their training leads them to consider a fact "proved" when there has been a larger and more voluble assertion of belief in its favour than against it. Some judges not only do not seek scientific proof, but regard the most extravagant theories as seriously as they would an indictment for murder.

**And  
Compensation.**

SOME other judges, however, preserve a reasonable equilibrium, which is as much as can be expected of men of legal training who are unaccustomed to deal with science and scientific matters. Before these judges, sitting as arbitrators under the Workmen's Compensation Act, justice is meted out with a certain approach to accuracy, but the margin which is left for the successful establishment of some wild claim is still a large one. A case which came up in the City of London Court last week for re-opening had been decided last December, when the workman,

a hairdresser, claimed that he had cut his hand with scissors, and subsequently "poisoned" the wound with a spirit lotion he used for shampooing. To these "accidents" he attributed eczematous ulceration of his hands, but the Court decided against him. There are a good many judges who would have done otherwise, but with however much sympathy one may regard a disabled workman, it is hardly possible to entertain such a proposition as that put forward in the light of what is known in medicine. It is equally, or almost equally, impossible to deny it, simply because no one can say, in many cases, why certain persons idiosyncratically develop eczema of the hands. This case, which seemed a trivial one to start with, has since assumed a more serious aspect, as it was stated in evidence that the man had been to several hospitals and seven or eight doctors, none of whom could do anything effective for him, and the trouble is likely to remain for years. The judge, however, refused the application to re-open, as he was bound to do, but without costs. This is a sample of the type of case which has to be decided every day under the Act, and it shows the danger of legislation going in front of science, instead of following in its well-beaten paths.

**Aneurism  
an  
Accident.** A FURTHER example of the fatuous position which the law has reached in relation to accidents, was given by a decision rendered in the Court of Appeal, last week, in *Hughes v.*

*Clover, Clayton and Co.* The appeal was made by the Company against a decision of the County Court judge of Lancaster, sitting as an arbitrator under the Workmen's Compensation Act. The workman in this case had a large aortic aneurism, which was liable to burst at any moment, and whilst tightening a nut with a spanner, but not using more than ordinary force in doing so, rupture took place and he fell dead. These were the facts found, and on them the judge held that death had taken place from accident within the meaning of the Act, and awarded compensation accordingly. The Court dismissed the appeal of the employers, holding that the county judge had decided rightly. They held that the man, admittedly suffering from an aneurism, had incurred a strain, of a not extraordinary character, in the course of his work, and that this strain caused the rupture of the aneurism; therefore they found that the case came within the law as laid down by recent decisions, and that therefore the workmen's dependants must recover. We do not dispute that, as the law has developed lately, this decision stands good, but we do think that this development of the law is an outrage on common sense.

**Is Work  
an  
Accident?** THE workman was performing a very ordinary task, requiring no undue exhibition of force, and he died of a rupture of an aneurism, which was merely the extension of a pathological process which had been going on for months, probably for years. It is as ridiculous to say that it is an "accident" to tighten a nut, which the man deliberately set himself to do, and did in the ordinary way, as it would be to say that walking or sitting up in bed was accident if rupture had occurred whilst he was performing either of these actions. If ever a man dies of a disease-process he does so when he dies of rupture of an aneurism, and only by a gross distortion of the English language can he be said to die of anything else. We do not think it is possible, in the present state of medical knowledge, to say what

share, if any, external circumstances take in hastening a rupture which is bound to come. For instance, had the man walked rapidly to his work, and the rupture taken place when he was doing so, bleeding would have begun before he started tightening the nuts at all, and it must be almost impossible to say in any given case whether bleeding had been going on gradually for half an hour, or whether a sudden rent occurred in the sac. In other words, it is impossible to say in such a case that anything in the man's employment had any connection with the rupture, whilst the large outstanding factor remains that, whatever he had been doing, the continuation of his life was only a matter of days or hours. From the point of view of workmen, these decisions, like all departures from the bed-rock of scientific knowledge and common-sense, are disastrous, for they simply drive employers to have their men medically examined, and in a short time no man with a defect of any kind will be able to obtain work in any capacity, owing to the employers' fear of having to pay compensation on a heavy scale for any trivial event that affects their health.

## LEADING ARTICLES.

### OPHTHALMIA NEONATORUM.

THE progress of reform in preventive medicine—all the world knows—is proverbially slow. This general principle has been forcibly illustrated of late years in the case of the most preventable of all diseases, ophthalmia neonatorum. As a cause of blindness it stands foremost; its cause is definitely a specific infection, of which by far the most common is that by the gonococcus. The second vital fact in the problem is that the infection is conveyed from mother to infant at or shortly after birth. By the use of certain aseptic or antiseptic measures employed about the period named the disease can be averted in ninety-nine cases out of a hundred. From this simple statement of fact it must be open to the apprehension of all persons, whether lay or medical, that this disastrous malady, responsible as it is for one-third of all the blindness in the civilised world, can be absolutely prevented by any well-thought-out and comprehensive scheme. The recent action of the British Medical Association in the matter affords some prospect that at length this most desirable end will be attained in the near future. Readers may remember that the body in question appointed in the course of 1898 a committee to deal with the subject. The composition of the committee, under the chairmanship of Mr. Sydney Stephenson, was sufficiently large and representative to guarantee a well-informed and impartial investigation into the whole question, and amongst other special interests directly represented were the ophthalmological, public health, midwifery and gynaecology, pædiatry, and bacteriology. As the outcome of the inquiry, an important memorandum was drawn up by the chairman of the committee, and upon this document a number of recommendations and conclusions were based. Some of the latter demand the careful consideration of all interested in the prevention of blindness. They are as follows:—"1. Ophthalmia neonatorum accounts for upwards of 10 per cent. of all cases of blindness. 2. Cases of ophthalmia show a slight but steady decrease, so far as can be

judged by returns from British lying-in hospitals and eye hospitals. 3. Ophthalmia is still the cause of at least one-third of the blindness in the inmates of British blind schools. 4. Cases of ophthalmia without adequate treatment have been found to occur amongst cases attended by medical practitioners, as well as amongst those attended by midwives." The vital nature of these propositions are self-apparent, a remark that applies with equal force to the preventive measures recommended by the committee. Notification naturally comes first on the list, and this, it is urged, should be made compulsory by the Local Government Board. This step, however necessary it may be in itself, may apparently foreshadow the notification of gonococcus infection amongst adults. The further recommendation that the bacteriological examination of vaginal or conjunctival discharges should be undertaken by the local sanitary authority, free of charge, appears to be quite in accord with modern views. The responsibility of seeing that cases thus notified are properly attended medically is thrown upon the local sanitary authority. The committee takes the common-sense view that, as far as may be, the treatment of infantile ophthalmia should not involve the separation of mother and child. The instruction of the public by local authorities is suggested, and more particularly that all midwives should be specifically warned as to the dangers of the disease and the preventive methods to be adopted. One of the most important remaining recommendations is that the presence of purulent vaginal discharges in parturient women should be included in the rules of the Midwives' Board among the conditions for which medical help should be summoned. The remainder of the committee's very able report includes directions to midwives and nurses, on the one hand, and to medical practitioners on the other. One noteworthy point is that the use by midwives of strong chemical applications (*e.g.*, Crédé's method) is not advocated. In many ways we regard this report as one of the most important that has ever been issued authoritatively by the medical profession for the guidance of the public generally, and of local administrative bodies in particular, as to the prevention of a malady that entails great disability upon individuals and an increasing economic burden upon the community.

#### THE ROMANCE OF SCIENCE.

WE publish elsewhere the first part of the address recently delivered at Stockholm by that veteran pathologist, Professor Metchnikoff, under the Nobel bequest. With the simplicity that comes of ample knowledge, the lecturer reviews the researches and the discussions that culminated in the recognition of phagocytosis as a vital phenomenon intimately concerned with the defence of the organisms against pathogenic bacteria from without. The results testify eloquently to the value of theoretical research since the hypothesis, owing to the special technical difficulties inseparable from this line of research, had to be based in great measure on deductions from very elusive phenomena. He tells us how the accuracy of each alleged discovery was wrangled over by intellectually-hungry professors, how first one school, then another, scored a point, only to be worsted in the

next encounter, how they boxed (with arguments in lieu of fists) strictly according to the rules of the game, shaking hands with each other as soon as the umpire of skilled opinion had given its award. There was a noble simplicity about the conception of phagocytosis that commended it for acceptance. It embodied the abstract idea of a combat between good and evil within the organism, akin to the struggle between moral forces in the psychical domain. At present, in spite of the vast amount of information that has been accumulated in regard to phagocytosis, we are still perforce mere spectators, unable to afford our friends the phagocytes any very substantial assistance in the warfare they are waging on our behalf. Even such a distinguished bacteriologist as Metchnikoff, when it comes to explaining the intimate mechanism of immunity, is fain to admit that he sees "as through a glass, darkly." He describes to us the tactics of the besiegers and the besieged, how they squirt soluble substances at each other that cripple or paralyse, and so render the enemy on either side amenable to absorption and disintegration. He paints a lurid picture of the phagocyte that has absorbed more bacilli than it can assimilate, and how it is burst asunder, with the result that the invaders carry the citadel. So far the doctrine of phagocytosis has only been empirically applied to the control of disease. Poultices assist the organism in resisting infection by attracting a plentiful supply of leucocytes to the field of battle, and Bier's method presumably acts in the same way. Pus cells that were formerly regarded as the incarnation of all that was evil are now known to represent the marshalled hosts of our defenders doing battle with the septic germs, to be encouraged rather than repressed. Active efforts are being made to discover means of stimulating phagocytosis and of reinforcing the protective properties of our cellular defenders, and already something of the kind has been achieved by the injection of colloid metals, which, directly or indirectly, do materially aid in the scheme of defence. Outsiders can have little idea of the well-nigh insurmountable difficulties that are met with in the prosecution of this department of research, and of the immense expenditure of time, skill and energy required for the achievement of the slightest progress in this domain. Honour to the men who, undaunted by obstacles, unremittingly pursue the investigations from which we are entitled to hope so much.

#### CURRENT TOPICS.

##### A New Ophthalmological Congress.

WE are pleased to be able to give an early announcement to our readers of the inauguration of a new Congress of Ophthalmology. Those interested in that branch of medical work know that for the last four years an informal meeting of ophthalmic surgeons has been held every summer at Oxford. The proceedings thereat included the reading of papers, discussions, examination of cases and appliances, and the performance of new operations. On July 15th it was moved in the Common Room in Keble College by Mr. Sydney Stephenson, seconded by Dr. R. A. Reeve, Dean of the Medical School at Toronto, and carried unanimously, that the meeting should be placed on a

permanent footing. The motion received the support, amongst others, of Prof. Deutschmann (Hamburg), Prof. Motais (Angiers), Prof. Dufour (Lausanne), Wendell Reber (Philadelphia), Dr. Vail (Cincinnati), Dr. R. J. Coulter (Newport), Louis Werner (Dublin), and H. Walker (Glasgow). Prof. Osler then moved, and Dr. Grainger, of Chester, seconded, that a new Society be formed under the title of the Oxford Ophthalmological Congress. With a view of carrying out the necessary organisation, a committee was formed consisting of Sir Anderson Critchett, Sir Henry Swanzy, Prof. Osler, Dr. Hill Griffiths, Dr. George Mackay, with Mr. R. W. Doyne as Chairman, and Mr. Sydney Stephenson as Honorary Secretary.

#### Fatal Hair Washes.

THE reckless use of dangerous drugs by hairdressers has led to many accidents, some of them fatal. Some of the dyes used by them contain nitric acid and other potent ingredients, and we have seen a society woman with her hair destroyed and a deep slough on the ear caused by a careless application of acid. Cases have been reported of death due to lotions containing corrosive sublimate. Some years ago it was the fashion to sell lotions containing petrol and benzine for dressing the hair and cleansing the scalp, but the occurrence of several deaths, due to explosions from accidental ignition of the vapour thrown off from the mixture, led to their discontinuance in the United Kingdom. Not long ago a case occurred in Paris in which an actress was killed as the result of the ignition of an explosive vapour by a stove at a distance of several feet. Another risk is that of anæsthesia from the use of volatile drugs giving off anæsthetic vapours. At least two cases have been recorded from the use of carbon tetrachloride, one of them connected with the hairdressing branch of a well-known London store. That particular drug was introduced as an anæsthetic some years ago, but proved too feeble for general use, and it has been practically forgotten by medical men until brought into notice again by the recent tragedy. Surely it is not too much to ask the Home Office to exercise some sort of supervision over hairdressers and other scientifically untrained persons who deal in such terribly dangerous drugs. If a medical man were to give a patient such a lotion and death were to result, he would most assuredly be held responsible for his remissness. Why, then, should a grossly ignorant person be permitted to handle the same drugs with impunity? If the Home Office, with these tragedies on record, does not take immediate steps to put a stop to the use and sale of deadly drugs by hairdressers, the responsibility of future damage and death must lie at their official door.

#### A Norwich Scandal

At an inquest held at Norwich on July 20th, before the City Coroner, Dr. Crosse, who made the post-mortem, asked leave to make some remarks, and, being allowed to do so, he said that the post-mortem in that case had to be made on a sofa in a room in which the window was screwed down, and that on a subject who had been dead for forty-eight hours in the height of summer. These surroundings, he said, were luxurious compared with some he had had to put up with in Norwich. He had made post-mortems on feather beds, kitchen tables, chests of drawers, and even on the floor. He had had to use dinner-plates and dishes on such occasions for the purposes of the examination, and, in spite of all precautions, it was frequently impossible to prevent

relatives and friends from coming in, while a gaping crowd of neighbours not infrequently would gather round the door and discuss the case. Representations had been made by medical men again and again, individually and collectively, but without effect. The present mortuary accommodation was quite inadequate for a place of the size of Norwich. We cannot express our own opinion better than by repeating some words used by Dr. Crosse. "All this," he said, "is disgusting, degrading, and indecent." It is, and had it not been publicly stated by a medical man of repute we could not have believed it. Norwich has acquired the proud title of the "ancient and religious city"; till it alters its mortuary arrangements we can only think of it as a home of squalor and barbarism.

#### The Newcastle Coroner and Dr. Coley.

WE had occasion recently to comment on the way in which the Newcastle Coroner had treated Dr. Coley of that town at an inquest, and we find that the Coroner, having had his insinuations and mistakes pointed out to him in a very temperate letter written to the press by Dr. Coley—the only form of public defence open—took occasion at the adjourned inquest to make a still graver statement, namely, that he had not understood that Dr. Coley had examined the patient. The suggestion here implied was effectively exposed by a further letter by Dr. Coley, to which the Coroner again replied at another inquest by making a long statement to cover up the false position he had originally assumed, and introducing details which appear to have been so distorted in his mind that, instead of clearing Dr. Coley, they made him appear in a still less advantageous position. Again Dr. Coley addressed the press in a letter marked by great courtesy and good sense, pointing out the fallacies alleged, and saying, *inter alia*, "In many cases the reckless observations of coroners have given undeserved pain and have cruelly injured the reputation of professional men." Such, alas! is too often the case, and it is lamentable that men in their position should so often use their privilege in a way which misleads the public and injures medical men at the same time.

#### Illness and Trials.

Two cases in prominent notice last week brought out again a point in law often urged, namely, that when a person asserts that he is unable to attend a law court for trial on account of illness, the court should send an official medical examiner to report on the person's state, and that it should be guided by his certificate alone. The first of these cases was that of Mr. Benson, whose trial for alleged frauds in connection with Feltham's Bank has been postponed two or three times on the ground of illness. Another postponement was applied for last week, and two medical men gave evidence of his state of health, and the Lord Chief Justice said that he was not satisfied with what they said. The other instance was that of the redoubtable Miss Charlesworth, who since her re-appearance on earth after her motor accident has three or four times failed to meet her creditors before the Registrar in Bankruptcy, she also alleging reasons of health for her absence. Exophthalmic goitre was first put forward, and last week "train-sickness" was alleged. The Registrar spoke strongly on the subject, saying certificates of health are sometimes too freely given, and, finally, that if the debtor failed to appear at the next sitting he would issue a warrant for her arrest. It is clear that a medical man who is attending a private patient is bound to say what he legitimately can in patient's favour in a certificate, and it is also clear that the

excitement of a court trial is good for no illness that one knows of. On the other hand, there at times are questions of public policy involved with which it is not a medical man's business to concern himself, and the point a court has to decide is whether the detriment to health outweighs the detriment to public morals. It is not fair to try to throw this burden on a private practitioner, and we hold strongly that the court should send its own official medical referee to consult with the patient's attendant, and to issue a report on which the court should act.

#### A Tuberculosis Dispensary for Dublin.

FOR some eighteen months past the Dublin hospitals have in their out-patient departments paid special attention to the home treatment of tuberculosis, working in connection with the Women's Health Association. The latter body has provided health visitors and nurses for such tuberculous patients as were willing to receive their help. We learn that, as a result of Lady Aberdeen's recent visit to America, a development is to take place in this line of work. Mr. Collier, a wealthy American of Irish family, has offered sufficient funds to equip and maintain in Dublin a dispensary for tuberculosis on the lines of those run in various large cities. The details of the scheme are not yet filled in, but the venture is one which deserves every success. No disease lends itself more to home treatment, and in none is wise control of house treatment more important. We have great hopes, therefore, that a judiciously-conducted tuberculosis dispensary may be an active factor in the campaign against the disease in Dublin. We have no doubt that in the organisation of the dispensary Lady Aberdeen will be guided by the best medical opinion.

### PERSONAL.

ON July 23rd the King, accompanied by the Queen and Princess Victoria, opened the new in-patient department of the Royal National Orthopaedic Hospital, Great Portland Street, W. The King was received by the Duke of Marlborough, the Earl and Countess of Denbigh, the Mayor and Mayoress of Marylebone (Colonel and Mrs. Alfred J. Hopkins), Sir R. B. Martin and Sir Samuel Scott, M.P. (Hon. Treasurers), Mr. J. R. Cooper (Chairman of the Executive Committee), Miss Hunt (Treasurer of the Ladies' Committee), Mr. Muirhead Little (Senior Surgeon), and Mr. Arthur Morley (Secretary).

PRINCESS CHRISTIAN and Princess Victoria of Schleswig-Holstein attended the "View Day" of the Frimley Sanatorium and Convalescent Home attached to the Brompton Hospital for Consumption on July 17th.

DR. ISAAC MOSSOP has been appointed by the Lord Chancellor to be a Justice of Peace for the City of Bradford.

MR. F. N. DOUBLEDAY, L.D.S., has been awarded the Guy's Hospital Travelling Scholarship of the value of £100.

THE University of Geneva has lately conferred upon Lord Lister the honorary degree of Doctor of Medicine as an appreciation of his epoch-making contributions to surgery.

THE eleventh South African Medical Congress will be held in Durban, August 2nd to 7th, 1909. His Excellency Sir Matthew Nathan, K.C.M.G., R.E., the Governor of Natal, will open the proceedings.

The President of the Congress is Dr. H. A. Dumat, and the Vice-Presidents are Drs. W. Watkins-Pitchford and W. J. Hill. The Hon. Secretary is Dr. P. Murison, and the Hon. Treasurer Dr. G. L. Bonnar.

PROFESSOR WILLIAM STIRLING, M.D., Dean of the Medical Faculty and Professor of Physiology in Manchester University, has been nominated to represent the University as its official delegate at the forthcoming quinqucentenary of the University of Leipsic.

MR. S. G. KIRKBY-GOMES, late Professor of Surgery in the Imperial College of Medicine, Tokio, has been appointed Representative of the Ceylon, South India and Madras branches on the Council of the British Medical Association, in succession to Surgeon-General Brown.

THE following Fellowships have been awarded as the result in recent examinations at the University of Liverpool:—Robert Gee Fellowship in Anatomy, R. H. Mole, M.D.; Holt Fellowship in Physiology, C. H. H. Harold, M.B., Ch.B.; Thelwall Thomas Fellowship, W. W. Mackarell, M.B., Ch.B.; Ethel Boyce Fellowship, W. R. Pierce, M.B., Ch.B.

THE honorary degree of M.D. of the University of Dublin has been conferred upon the following medical men:—Sir Alfred Keogh, M.D., K.C.B., Director-General of the Army Medical Service; Dr. W. Hale White, senior physician to Guy's Hospital; Dr. W. P. Herringham, physician to St. Bartholomew's Hospital; Dr. G. A. Gibson, physician to the Royal Infirmary, Edinburgh; and Dr. G. Redmayne Murray, Professor of Pathology in Victoria University, Manchester.

THE prize-winners at the Royal Army Medical College at the recent examination at the termination of the junior course were:—Lieut. H. S. Ranken, R.A.M.C., the Herbert, De Chaumont, Tulloch Memorial, Ranald Martin, and Marshall Webb prizes; Lieut. J. A. Manifold, R.A.M.C., the 1st Montefiore prize; Lieut. C. L. Franklin, R.A.M.C., the 2nd Montefiore prize; Lieut. A. M. S. Jukes, I.M.S., the Parkes Memorial prize; and Lieut. B. Gale, I.M.S., the Fayrer Memorial prize.

THE following appointments have been made to the medical staff of St. John's Hospital for Diseases of the Skin:—Dr. William Griffith, M.B., Vict., M.R.C.P., has been appointed Assistant Physician; Dr. C. A. McBride, M.D., C.M. Toronto, has been appointed Casualty Officer; and Miss Louisa Woodcock, M.D. Lond., has been appointed Clinical Assistant.

A TELEGRAM from Rio de Janeiro dated July 17th states that Dr. Oswaldo Cruz, Director-General of the Sanitary Service, announces that the bacillus of smallpox has been discovered in the course of bacteriological researches carried out at the Oswaldo Cruz Institute by Drs. Henrique Beaurepaire de Aragao and Prowazek.

AT the International Congress of Nurses at the Caxton Hall, Westminster, Lady Helen Munro-Ferguson, lady president of the Home Committee of Lady Minto's Indian Nursing Service, and a member of the Advisory Council of the Territorial Force Nursing Service, occupied the chair.

A STATUE was erected in the Ranelagh Gardens, Chelsea Hospital, in September, 1865, in memory of Sir James McGrigor, Bt., the first Director-General of the Army Medical Department. For a considerable time past it has been felt that the new Royal Army Medical College, Grosvenor Road, would be a more fitting place for this memorial. Permission having been obtained from the various authorities concerned, the statue was transported and re-erected recently on a site in the grounds of the college on the north-east side and facing the Tate Gallery, the cost being defrayed by the officers of the Royal Army Medical Corps.

# A FRENCH CLINICAL LECTURE

## ON

### A STUDY OF ACUTE TUBERCULOUS RHEUMATISM.

By ANTONIN PONCET, M.D.,  
Professor of Clinical Surgery at the Faculty of Lyons,

AND  
M. LERICHE, M.D.,  
Surgical Registrar at the Lyons Faculty of Medicine.  
[SPECIALLY REPORTED FOR THIS JOURNAL.]

RHEUMATIC troubles of bacillary origin are met with in three different forms. In one variety there is vague pain, either spontaneous or provoked, more or less localised in the joints or extending down the limbs. A second variety is characterised by acute arthritis, sub-acute mono-articular, or poly-arthritis, closely resembling ordinary acute rheumatism, while in a third variety there are chronic arthropathies, with a tendency to ankylosis.

*Arthralgia.*—Under this name we must include a whole series of rheumatoid manifestations, more or less limited to the joints, which are frequently met with in tuberculous subjects. Tuberculous subjects, indeed, are liable to many "algias": myalgia, muscular hyperæsthesia, facial neuralgia, intercostal sciatica, &c., the result of toxæmia. The joint pains are due to slight, purely inflammatory changes in the bones or synovial membranes. The pain may occur spontaneously, or be elicited by manipulation; it is rarely very severe, being, as a rule, vague, ill-defined, and increased by exercise and fatigue. As a rule, it subsides with rest, but is sometimes very refractory to treatment. Many joints may be affected simultaneously, but the pain is always more pronounced in the large than the small joints. It is often complained of in the region of the spinal column, giving rise to errors of diagnosis.

The various "algias" deserve attention, for they may be premonitory of latent tuberculisation. They may long precede more virulent lesions, so that their recognition is important. In children and adolescents they are often ascribed to osteitis, or "growing pains," and their situation in the epiphyseal regions renders a mistake all the easier. Osteoarthralgia is not infrequently met with in tuberculous subjects at the stage of caseation, and it may be the only remaining trace of cured tuberculosis. Barbier makes a distinction between osseous and muscular hyperæsthesia, which are particular manifestations of tuberculous rheumatism to which we shall have occasion to refer later. Their characteristic feature is the absence of any objective sign, there being neither swelling nor redness of the soft parts, their variability and fugitive character, flying from one joint to another, ultimately taking up their residence, it may be, in a rather brutal fashion in one particular spot.

*Acute and Sub-acute Tuberculous Rheumatism.*—This form is characterised by sudden effusion into one or several joints, presenting the closest possible resemblance to ordinary acute rheumatism. Less frequently met with than the preceding form, it often escapes recognition, being mistaken for ordinary rheumatic fever. Now, it cannot be too strongly urged that the diagnosis of polyarticular rheumatism amounts to nothing; we must go beyond this gross morphology, and seek by every means in our power to establish a complementary pathogenesis. With perseverance and practice it will often be possible to satisfy ourselves that the rheumatic fluxion is only a prominent indication of a masked infection, and not a disease *per se*. In regard to tuberculosis, more than any other disease,

it is of the greatest interest for us to arrive at an opinion on this pathogenesis.

Tuberculous rheumatism, which often supervenes in the course of existing tuberculosis, medical or surgical, during the germinative period of recent tuberculosis, is often the earliest manifestation of tuberculous infection, often long antedating the further symptoms.

Of 100 patients admitted to the Lyons hospital for rheumatic joint lesions recognised to be tuberculous, in thirteen the joint symptoms constituted the first indication; of 100 admittedly tuberculous patients, in twelve there was a history of acute articular rheumatism at some previous date.

The symptoms of acute tuberculous rheumatism are hardly to be distinguished from ordinary acute rheumatism or acute pseudo-rheumatism. The suddenness of its onset, without any premonitory symptoms, resembles that of certain infective arthropathies, especially gonorrhœal affections. It is specially apt to attack the larger joints, knee, hip, elbow, wrists, feet, &c.

The general state of the patient, the pulse and the temperature, depend far more on the degree of constitutional infection than on the arthropathies which are the manifestations thereof. A grave general state, with joint lesions of medium severity, often constitutes a presumption in favour of tuberculous rheumatism.

Certain peculiarities at the onset and towards the termination deserve special mention. Tuberculous rheumatism may recur at more or less distant intervals, the intervals being quite free from any trouble of the kind. This point is important, because it is one cause of confusion with ordinary rheumatism.

Its duration is variable. It may disappear in a few days or last for weeks, with exacerbations and remissions. Sometimes it flies from joint to joint like ordinary rheumatism; sometimes it runs a protracted course, with painful outbursts which, when frequently repeated, are the precursors of chronic deforming arthritis. In other instances it remains localised in one or several joints with an obstinacy that recalls gonorrhœal rheumatism.

Later on we shall have occasion to refer to its termination in fungous transformation or ankylosis, but it often subsides altogether without leaving any trace.

Having enumerated these general characters, we must make a distinction between two principal varieties of rheumatism, based upon the conditions under which they supervene—viz., primary and secondary. We have already insisted on the importance of this distinction; the first form possesses diagnostic and prognostic importance of the first order; the second is only an episode of uncertain prognostic importance which does not materially influence the pathological situation of the tuberculous subject affected thereby.

*Primary Acute Tuberculous Articular Rheumatism.*—Of this there are two forms, one in which the tuberculous rheumatism attacks the serous membranes as well, so that, side by side with the

arthropathies, we get pleurisy, pericarditis, &c. In the other form it is limited to the joints.

*The Acute Diffuse Serous Form.*—This is not very common and only accounts for some 15 per cent. of cases of primary acute rheumatism. It is easy to recognise by its typical course. A young subject in the best of health, or in a state of morbid imminence by reason of overstrain or worry, is suddenly seized with acute inflammation of the joints accompanied by a rise of temperature, dyspnoea, rapid pulse, and sweats. The constitutional symptoms are well marked, and one has the impression of a grave form of infection. The joints are hot, red and painful, and incapable of the slightest movement. The general health becomes more and more unsatisfactory, and we get inflammatory mischief in the great serous membranes, pleura, meninges, or peritoneum, either simultaneously or consecutively. Each fresh attack is ushered in by a further rise of temperature and a recrudescence of the constitutional symptoms. Recovery may take place, but more frequently the patient succumbs to generalised tuberculosis. The joint troubles, which sink into insignificance before the other manifestations, persist until the end. The disease may run on for months, its course being characterised by intermissions and exacerbations.

This variety of tuberculous rheumatism, which is especially interesting on account of the supervention of the joint troubles as a prelude to the graver manifestations, is closely allied to articular granulia. The clinical aspect is the same in both, and the picture is that of ordinary acute rheumatism. The diffuse form, however, does not run such a destructive course as synovial granulia, otherwise they are practically indistinguishable.

On the other hand, the presence of granulations in the one and their absence in the other enables us to distinguish between the two.

*Simple Acute or Sub-acute Form.*—This is the commonest and most interesting form, as well as the most useful to become familiar with on account of its semeiological importance and nosological bearings. It occurs mostly between the ages of twenty and thirty years, and the attacks recur at uncertain intervals without any settled periodicity. It would seem that the joint fluxions are the more numerous the less the subject is prepared by heredity or personal antecedents to tuberculosis. On the contrary, in individuals who are hereditarily predisposed, in the subjects of toxæmia, in the overwrought, in fact, in all who easily fall victims to the tubercle bacillus, premonitory disturbances are rare or unique. As Mazot aptly remarks: "there is no preface to such a short chapter."

The symptoms then present themselves in two phases. The first stage is marked by acute joint troubles which monopolise one's attention, to the exclusion of any other pathological causation. In the second we get more virulent localisations in a joint or some other organ, and the rheumatic arthropathies run a "crescendo" course.

The initial articular troubles are in no wise characteristic. There are several outbursts of poly-arthritis akin to ordinary acute rheumatism. These outbursts run a most uncertain course. Some improve in a few days, to be followed at regular intervals by recurrences, or persist for weeks or months without being in the least benefited by the salicylate treatment.

The general health, already unsatisfactory, is gravely compromised, the patient loses flesh and strength, the appetite diminishes, and the fever increases, in fact, we get the whole series of symptoms characteristic of latent tuberculosis, without any auscultatory sign, the joint troubles

attracting our attention to the exclusion of the rest. The inefficacy of the specific treatment is an aberrant, odd case of rheumatism causes surprise, and makes one think of pseudo-rheumatism, and the cause is looked for in every direction except that of tuberculosis.

By and bye the articular manifestations improve, the arthropathy becomes localised in one or several joints, and assumes a chronic form or disappears. The apparent rheumatism is succeeded by frank tuberculosis. The first act has come to an end. Then we enter on the second stage, which presents three types according to the bacillary localisation and the termination of the initial arthritis:—

(a) In the first type the tuberculous process attacks one or other organ—lung, intestine or testicle—and the arthropathies subside without leaving any trace. They retrocede as soon as we get the initial symptoms of visceral tuberculosis, or much later. In such case the tuberculous rheumatism and the more virulent lesion run their course side by side independently of each other for weeks, or it may be for months. Sometimes the rheumatism disappears before the tuberculosis, which it precedes, has broken out. A variable lapse of time intervenes between recovery from the arthritis and the clinical onset of the fresh localisation, and during this time the patient is now apparently in perfect health, in fact, quite cured. This variety of tuberculous rheumatism, just like ordinary acute rheumatism, is characterised by the possibility of complete recovery without leaving any trace of damage in the joints attacked.

(b) In the second type, after a very acute onset, the arthropathies partially retrocede, but some joints remain inflamed and become ankylosed, do what we may. Soon, or it may be after a long interval, we get discrete signs of pulmonary tuberculosis. A patient of ours who had been living in a tuberculous environment was seized with acute rheumatic poly-arthritis, which did not subside for a long time. When the pain subsided, it was found that one elbow, one wrist and one foot were ankylosed, and radiography showed the ankylosis to be bony. Two years later this patient manifested mild symptoms of infiltration of one apex, the nature of which was confirmed by a very positive sero-reaction. We shall refer to ankylosing arthritis later.

(c) A third type is characterised by a tendency for the inflammatory symptoms to become localised in one or two joints, which slowly become fungous. This is by no means uncommon. It runs a slow course. The diseased articulation remains swollen and is painful on certain movements. From time to time, following fatigue or effort, there is a fresh outbreak of inflammation which clears up very incompletely. This state may persist for years. It is still thought to be a case of chronic rheumatism, when the earliest signs of visceral tuberculosis make their appearance, thus establishing the exact pathogenesis of the joint affection. Little by little things become cleared. The diseased joint increases in size, there are tender spots, and it runs the ordinary course of tuberculous arthritis. Long before the appearance of any fungosity inoculation of the synovial fluid in a guinea-pig gives rise to tuberculosis. When tuberculosis invades several joints already attacked by tuberculous rheumatism, it may assume various forms, fungous synovitis, plastic synovitis, rice grains, hydrops, tuberculosis, in fact, the whole gamut of lesions engendered by the tubercle bacillus.

(d) A last type is characterised by the transformation of the initial arthritis into simple chronic rheumatism. To begin with, the affection presents some resemblance with those just described, but

the lesions remain of the chronic inflammatory type. Its nature is usually made clear by the evolution of tuberculous lesions elsewhere, in the lungs, glands, &c.

**Acute Secondary Articular Rheumatism.**—Acute rheumatism supervening in the course of clinically appreciable tuberculous lesions is by no means rare. Until quite recently these joint troubles were looked upon merely as arthritic manifestations, and they used indeed to be considered of favourable augury, in view of the hypothetical antagonism of arthritis and tuberculosis. No such antagonism exists. The apparently arthritic subject whose tuberculosis has undergone sclerosis is merely an ordinary tuberculous subject suffering from bacillary rheumatism. The arthritis was tuberculous from the onset. Before the discovery of the bacillus we were fain to invoke mixed infection to explain the production of rheumatic white swelling. The straightforward conception of inflammatory tuberculosis greatly assists us in understanding all this. The continuity of action of an ever-present infection readily explains the various reactions observed in particular patients, as, for example, in the case of a patient of Paviot's, at the Perron Hospital, who, after a strumous sickly childhood and severe anæmia at puberty, developed facial lupus at nineteen, followed a little later by acute articular rheumatism, with two or three recurrences, culminating in arthritis deformans.

Many such cases might be related, some of them even more complicated, which can only be explained on the hypothesis of a tuberculous origin. In most of them we find a constant relationship between the joint troubles and the visceral lesions; as the one recedes the other gets worse. This alternation of pathological phenomena is often mentioned by the patients themselves. It is the general rule until some grave localisation (suppurative osteo-arthritis of a large joint, Pott's disease, &c.) supervenes, whereupon the type becomes fixed, the fluxional metastatic type disappearing.

Nevertheless, we most commonly meet with attenuated lesions with fibroid tendencies, which therefore run a slow course, the patients often living for years. This is vastly different from arthritis, for the symptoms as a whole are due to the original virulence of the micro-organism.

NOTE.—A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by D'Arcy Power, F.R.C.S. Eng., Surgeon to and Lecturer on Surgery at St. Bartholomew's Hospital. Subject: "A Case of Heredo-Syphilis."

## ORIGINAL PAPERS.

### A BRITISH MEDICAL REMINISCENCE.

By H. MACNAUGHTON JONES, M.D., M.Ch., M.A.O.

Formerly University Professor of Midwifery in the Queen's University, Ireland.

To take a glance into the tablets of memory and recall the scenes and events of the past is not unusual on the anniversaries of institutions and associations. So it appears to me to place, however so faintly, on the screen of the present the recollections of an annual gathering of the British Medical Association in Ireland must be of interest on the anniversary in Ireland of the first provincial meeting, on this, the fourth that has occurred in the sister isle. It is a long hark back to the foundation by me in 1876 of the "South of

Ireland," the premier branch of the Association in Ireland. At the time my old friend the then Editor of the *Journal*, Ernest Hart, thought that such an effort would prove a failure, and rather discouraged the idea, but within a few weeks from the reception of his discouraging letter I received one from the Council of the Association in London conveying its thanks for the formation of the branch. I then had associated with me one of the most versatile and brilliant intellects the Irish schools have provided in the last half-century, the late Ringrose Atkins, then attached to the Cork Lunatic Asylum under Dr. James Eames, and afterwards Resident Medical Superintendent of Waterford Asylum, who subsequently, with Dr. Denis O'Connor (junior) acted as Assistant Secretary to the meeting. Without his assistance it is doubtful if I could have brought either the formation of the branch or the meeting to a successful issue. In talking to the late Professor Charcot, who was present in 1879, he said that the best artistic microscopical delineations of the changes in the brain of the insane he had seen were those of Ringrose Atkins. Some beautiful sections of these in cases of insane alcoholics I still have and prize. Also, at that time, the then "Queen's" College had at its head a President who entered most heartily into every scheme that might in any way advance the interests of the College, and especially those of its medical school. During his Presidency the College in 1882 reached the high-water mark of its prosperity. Dr. W. K. Sullivan, a most distinguished chemist, was an ideal collegiate head. Expansive and liberal in all his views, having from his training German ideals of University education and practical teaching, his aim was to make the College a centre of technical instruction in the faculties as well as a fountain of general culture for Munster.

Therefore, he threw himself whole-heartedly into the project of bringing the Association to Cork, and when it met gave over the entire College to the needs of the meeting, and placed all the keys in my keeping for that week, making me rather nervous of the responsibility from the fact that I had before my mind the comparatively recent burning of part of the College buildings, supposed at the time to be the work of some fanatic or vindictive incendiary. In 1877 the Association met in Manchester at Owens College. There are some who will remember the hospitable efforts of Ross, one of the ablest of neurologists; Leech, the genial therapist; and those most popular of surgeons, E. Lund and Thomas Jones, to make that meeting the success it was. While attending it I sounded the then President of the British Medical Association, the late W. D. Husband, of York, as to the possibility of the Association visiting Cork in 1878, and, receiving a favourable answer, in September, at the instance of the local branch, I convened a meeting of the profession of Cork and the South of Ireland to invite the Association to meet in the southern capital in 1878.

It must be remembered that we had then only some thirty-five medical men in the City of Cork, whereas there are now over eighty, so it was not to be wondered at that the proposal somewhat staggered my medical friends and "alarmed" our future President when I made it. I have the original invitation as it was issued before me as I write, and of the thirty names appended to it, only seven now survive on the Register: Dr. N. J. Hobart, Professor Henry Corby, and Drs. Adderley, D. Donovan (M.O.H., Cork), Hadden, D. O'Connor, and J. E. Bull (S.A.). The courteous reply of Mr. Husband to that invitation conveyed the information that, as far back as 1874, at the Norwich meeting, Bath had invited the Association to that city, and that this prior claim, again urged, had to be acknowledged for 1878, but that the Association would be pleased to visit Cork in 1879. Dr. J. R. Harvey, my predecessor in the Obstetric Chair in the College, was chosen President, but he had to decline the position as he was then retiring from practice and leaving Cork, and Dr. D. C. O'Connor, Professor of Practice of Medicine in the College, was elected in his stead. No one who still remembers the dignified and venerable President, who, the year following the meeting, received the honorary degree of LL.D. of Cambridge University, can forget how admirably he filled his

post. A Dublin University graduate in Arts and Medicine, and educated in Paris, a disciple of Laennec, he occupied the Chair of Medicine from the opening of the College until his death. He was a cultured physician, and gentleman of the old school—a type to whom the unwritten laws of medical ethics and etiquette were more sacred than those more modern and written ones, which are the outcome of a veiled trades unionism and protectionist policy. In 1878 I worked through the Bath meeting as Vice-President of the Obstetric Section, under my old friend Alfred McClintock, ex-Master of the Rotunda, and the accomplished author of "Smellie's Life" for the Sydenham Society. Here I met for the first time the late Marion Sims, one of the most delightful of personalities. Together we went to the Royal Bath Hospital, where we saw a number of interesting cases. Dr. Falconer, of Bath, a foremost figure in the Association at the time made an admirable President.

Out of the 500 names entered at the Cork meeting there are still 110 on the Medical Register. The anxiety as to its success was not lessened by the fact that rain fell without intermission during July, ceasing only on the Saturday previous to the opening Monday, and then, fortunately, came a gloriously fine week ending by a downpour on the Sunday following. This preliminary wet told on the numbers attending. But as a majority of visitors brought their lady relatives with them, this swelled the numbers considerably and taxed our local accommodation to the utmost. But this deficiency was met by the generous private hospitality of the reception committee and the citizens of Cork.

And what a meeting that was! Alfred Hudson, the Nestor of Irish Medicine, gave the address in medicine on "Laennec and his Work"; William Savory that in Surgery, and Andrew Fergus that in Public Medicine. Savory's address, the universal theme of admiration, was a masterpiece of erudition and eloquence which occupied some fourteen columns of the *British Medical Journal* of August 9th, 1879. It is interesting to note the subject of the address, "The Prevention of Blood Poisoning in the Practice of Surgery." As we read it now by the light of our most recent aseptic methods, we can only marvel at the prescience and early grasp of the essential principles of aseptic surgery which it showed; the sources of hospital contamination, the avenues of septic invasion, the advantage of thorough cleanliness and exclusion of air from wounds, the value and limits of antiseptic precautions. And yet in his dealings with Listerism, the outcome of Pasteur's researches and its results, that address is mainly of interest as proving how far short it fell of what subsequent experience has shown to be the ideal *technique* of an operative wound. At least he proved how necessary it is not to limit our attention to the person of the patient and the wound area. He spoke advisedly when he expressed "diffidence in his own judgment" on certain points, and that "if he were in error" his "words would prove no serious obstacle to the progress of truth." It is by such gradual following out of Pasteur's motto, "Perseverance in Effort" that Science ultimately reaches its goal. Andrew Clark, President of the Medical Section, dealt with the subject of Medical education, and his shrewd analysis of our methods have received ample confirmation in the development of the present rather chaotic system of sketchy teaching, hurried examinations, and superficial tests of knowledge which open the portals of practice just as the practitioner is beginning to find out how little of the various special departments of medicine he thoroughly knows. In the same address there were weighty words on vivisection which might well in this year of grace 1909 be read with advantage by some of the rabid fanatics and denouncers of medical research, who assume to themselves the rôle of critics and judges of the motives and actions of men whose sole object is to achieve, at the least cost of suffering to the lower animals, the saving of life and the lessening of pain in the human race. Professor William Tanner, known in my student days as "The Slasher," from his bold, if rather risky, surgery, was a pupil of the great Civiale, and one of the quickest lithotomists I have ever seen. In presiding over the Surgical Section he gave a historical survey

of the progress of medicine in Cork, declaring that this day should be "marked with a white stone in its history."

Henry Power delivered a classical address, reviewing the recent progress of Physiology, showing the rapid strides that just then were being made. He closed with a well deserved compliment to the then occupant of the chair in the College, Professor John Charles, Vice-President of the section, who has only recently resigned after having filled it with distinction for some thirty years. Eames, who came to Cork from Letterkenny, the able administrative head of the Cork Asylum, presided over the Psychology Section.

It was a notable feature of the Cork meeting that, not without some difficulty, I persuaded the Council of the Association to permit me to form sub-sections in the Surgical Section—viz., Ophthalmology, Otology, Laryngology, and Dermatology. Fear was expressed that this splitting-up would weaken the section. But it proved an unqualified success.

A sad event occurred in connection with one of these sections. Tilbury Fox, then in the foremost rank of living dermatologists, was to have been my guest and president of that section. I had a letter from him from Paris, whither he had gone shortly before the meeting to get quiet and to prepare his address. Suddenly came the news of his death. There was then cut off prematurely one of the kindest-hearted and most honourable of men. Professor T. McCall Anderson took his place, and gave an address in dermatology. Dr. G. H. Kidd, the Master of the Coombe Lying-in Hospital, President of the Obstetric Section, took for his theme the treatment of "Uterine Tumours by Dilatation and Ecraseur." What a "whole world" separates us from such an idea and the modern hysterectomy for myomata! In the section of Public Medicine, the President, T. W. Grimshaw (afterwards Registrar-General for Ireland) dealt exhaustively on every moot point then engaging attention in the advance of sanitary science. J. Paterson Cassells, in opening the sub-section of Otology, referred to it as a "memorable occasion, seeing that the subject of otology had received for the first time a distinct recognition in the proceedings of any Medical Congress in the country." On August 5th an important meeting was held in the waiting-room of the Eye, Ear and Throat Hospital, at which a large number of ophthalmologists were present, when it was resolved to suggest to the Council that in future a sub-section of Ophthalmology should form part of the programme of the annual meeting.

What a galaxy of scientific workers did not the meeting bring together! In Medicine, amongst others, Clifford Allbutt, Henry Bennet (the real originator of the "open-air" treatment), who read a paper on "Mountain Air Treatment of Phthisis"; W. H. Allchin, Borchardt, J. Barr, James Little, J. W. Moore, Southey, Squire, W. J. Collins, Norman Kerr, Walter Foster, Octavius Sturges, Mrs. Garrett Anderson, Saunby, Coupland, Donkin, W. Wade, J. M. Finny, Drysdale, Henry MacCormac, George Duffey, Sigerson. In Surgery: W. Adams, Edward Bennett, Antony Corley, R. W. Parker, Brodhurst, J. Cooper Forster, Wm. McEwen, Wm. MacCormac, Thomas Jones, Teevan, Mapother, W. Thomson, Edmund Owen, W. Spanton, W. Wheeler, George Wheelhouse, Robert McDonnell, R. Barwell, Berkely Hill. In Obstetrics: Lombe Atthill, Robert Barnes, C. J. Cullingworth, R. Kincaid, E. Malins, Tilt, W. S. Playfair, Arthur Macan, More Madden, W. Walter, Robert Edis, Dill, Graily Hewitt, Aveling. In Psychology: H. Dill, Herbert Major, Rabagliati, Hack Tuke, Rayner, Murray Lindsay. In Dermatology: Thin, Malcolm Morris, P. S. Abraham, Walter Smith, Wyndham Cottle, Colcott Fox. Jonathan Hutchinson (unavoidably absent) contributed a paper to open the discussion on "Lupus." In Ophthalmology: W. Brailey, Bell Taylor, E. Nettleship, J. Wolfe, C. E. Fitzgerald, A. H. Jacob, D. Little, G. Walker, W. McKeown, H. R. Swawzy, J. B. Story, Vose Solomon, E. Andrew. In Public Medicine: J. Notter, Littlejohn, Alfred Carpenter, Ballard, Chapman, H. Tweedy, Meymott Tidy. In Otology and Laryngology: Morell Mackenzie, Lennox Brown, F. Pierce, E. Woakes, Kirk

Duncanson. America sent Seguin, G. Beard, Rooke Ley, Wetzel, W. H. Byford, Laurence Turnbull, J. Hogden, Louis Yandell, Evanovitch, H. Horton, McCord, and L. H. Sayre. Australia sent R. Peel and H. Gilman. France sent Charcot, Ball, Bonnafont, Gueneau de Mussy. Germany sent Weber Liel and Hirschberg. Italy sent Pacchiotti; Switzerland, Cordes. But no such meeting could hope to be conducted to a successful issue without the aid of the permanent officials, and Ernest Hart (Editor), Alfred Carpenter (Chairman of Council), Alexander Henry (Sub-Editor), and Francis Fowke (General Secretary) were an invaluable back in any difficulty. A feature of the meeting apart from the pathological and the annual museums, was a special Sanitary Exhibition, to which exhibits were sent by firms from different parts of the United Kingdom, and in its six subsections the most recent improvements in sanitary appliances were shown. It is also noteworthy that then, for the first time, was Cork in part lit by electricity. Having a local guarantee from Messrs. Perrott of engine power, I made arrangements with the Société Générale d'Electricité, of Paris, to bring over sufficient plant to light up the approaches to the College and the College itself by the Jablochkoff system. This was done at the President's *conversazione* the first night, a marvellously smart piece of electrical work, and, on the next, all the approaches to the Opera House were lighted for the Mayor and citizens' *conversazione* in the same way.

Surgeon-General (afterwards Director-General) Sir Thomas Crawford received the gold medal of the Association for Surgeon Reynolds, the hero of Rorke's Drift. Important discussions were opened in all the sections, a few of the principal being:—"The Diagnosis and Treatment of Joint Diseases," "Subcutaneous Osteotomy," "Alcohol in Fever," "Lupus and Its Treatment," "Intra-Uterine Medication," "Intra-Tympanic Medication," "Cataract Extraction," "Glaucoma," "Mydriatics," and "Myotics." One of the events of the meeting was the interest aroused by Richard Norris's *ignis fatuus* hunt for the third corpuscular element in the blood. The columns of the *Journal* of the Association to the close of the year contained valuable papers that were read during the meeting. These were days before the Röntgen method of examination, the modern means of exploring the respiratory and digestive tracts, present-day cystoscopy and exploration of the ureters with kidney catheterisation, local and spinal anæsthesia, and Wright's opsonic method, could be availed of to assist in diagnosis or treatment. Serum and anti-toxin treatment was only in its early infancy; the whole array of synthetical remedies now in use was unknown; the modern surgery of the brain and nervous system had not commenced; the same might be said of the abdomen and the abdominal viscera; the peritoneum was still a bugbear, and the sacred immunity of the appendix and the bowel from the surgeon's knife yet existed; prostatectomy and the operation of Freyer had no place in text-books; radical ear operations were confined to trephining of the mastoid cells; MacEwen had not written his classical work; gynaecology was a term only coming into use, and the surgery of the adnexa had just had its start through Battey and Lawson Tait. Dermatology had not the Röntgen-ray or radium to assist in treatment; the older specific remedial methods were employed in syphilis; and there had not come into existence a host of new names associated with the classical features of various diseases not then differentiated or even recognised. This is but a glimpse at what these thirty years have done for medicine and surgery.

And so the Cork meeting passed off after a delightful week of hospitality and entertainment. The reception committee gave a dinner to some hundred of the officers and principal guests on the Monday. Nearly 2,000 attended the President's reception at the College on the Tuesday. The Mayor, Corporation, and citizens held a brilliant *conversazione* on the Wednesday. The entire of those attending, with their friends, were entertained at a luncheon at Besborough House by the late Ebenezer Pike on the Thursday. Over 300 sat down at the annual dinner that evening, when I was placed standing on the dinner table to return thanks for the

reception committee. On the Friday there was a garden party in the beautiful grounds of the College, and in the evening a concert was given in the Assembly Rooms, at which the proverbial beauty and musical talent of Cork were fully appreciated. A little incident of that concert was the admiration evoked when those two giants, Louis Yandell, of Louisville, and William MacCormac came in linked arm-in-arm, representing America and Ireland. Both had seen military service, one in the American Civil War and the other in the Franco-Prussian. No two more splendid types of physique could be imagined. Both were in their prime, though that same night I sat up with Yandell through a sudden bad attack of ague from malaria contracted in the war.

On the Saturday I accompanied one hundred visitors down the Irish Rhine, and the Duke of Devonshire hospitably entertained them at Lismore Castle. Sir George Colthurst generously received fifty at historic Blarney Castle. One hundred were taken by steamer to see the harbour, and the reception committee provided a *déjeuner* at Queenstown; others were invited on a trawling expedition by the Rev. W. Green, while another, the largest party, were taken to Killarney, and, having been driven through the Gap of Dunloe, were provided with luncheon at Durricunnihi Cottage and then were rowed through the lakes, being brought back to Cork the same day. With characteristic generosity, Messrs. Musgrave, of Belfast, subsequently to the meeting, provided luncheon baskets for an excursion to the Giant's Causeway, and the Naval authorities courteously sent a gunboat, while Mr. Walter Bernard, of Londonderry, acted as local secretary for a five days' excursion through picturesque Donegal.

Thus ended a famous meeting, having many other interesting events which I could chronicle, only that space does not permit. To three surviving younger aids to that meeting, now distinguished members of the Profession in Cork, I would desire, in conclusion, to say that I do not forget their help—Dr. P. J. Cremen, Dr. Gelston Atkins, and Professor Yelverson Pearson.

## ON IMMUNITY. (a)

BY PROFESSOR ELIE METCHNIKOFF,

Of the Pasteur Institute, Paris.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

I PRESENT myself in conformity with paragraph 9 of the statutes of the Nobel Trust in virtue of which every recipient of a prize is, if possible, to deliver at Stockholm, within six months of the award, a public lecture on the subject thereof.

Inasmuch as I had the honour, in common with my friend, Professor Ehrlich, of receiving the Nobel prize in medicine "for researches on immunity," this is the subject I propose to discuss. Now the study of immunity is a chapter of theoretical medicine, and as such is necessarily somewhat difficult to deal with before a public audience. But the theoretical problem in question has for object the resistance of the organism to disease, and as everything that relates to health is of interest to the public at large I shall take advantage of this fact to make my arguments as clear and simple as possible, if only to convince you of the importance of theoretical research.

It is not necessary to be a doctor or to have studied science to wonder how the human organism is able to resist the many injurious agents that threaten our existence daily. You must all have remarked that in families, the members of which are exposed to the same danger, and among troops and in schools where everyone lives under the same conditions, disease does not attack everybody indiscriminately. Some fall victims while others display relative immunity.

In years gone by only the vaguest reply could be given in answer to the inquiry as to the reason of this remarkable resistance of the organism, but since the ever memorable discoveries of Pasteur and his school, who discovered the means of affording immunity by vaccinating with microbes, the question

(a) Address delivered at Stockholm under the provisions of the Nobel Trust.

has been greatly simplified. It has become possible to study the subject by the experimental method. Pasteur, who was a chemist, explained the fact that the intact organism did not allow of the development of certain morbid agents by assuming that the chemical composition of the medium was unfavourable thereto. Just as plants will not grow on a soil which lacks some substance indispensable to their development—so microbes, the microscopical plants which cause infective diseases, are incapable of multiplying in an organism which does not provide them with the substances necessary to their well-being.

This theory, though quite logical, was however in contradiction with many facts met with in the immune organism. Pasteur and his assistants ultimately recognised this when they found that infective microbes develop freely in the blood of animals which are perfectly immune.

The animal organism is very complicated, so that it is difficult to explain in a simple manner what takes place inside it. To do this another plan had to be adopted. The problem had to be approached from the biological point of view, endeavouring to simplify the conditions without going outside the limits of the living organism. This is the idea that has guided us in our researches. Since disease is not the exclusive privilege of man and domestic animals it was only natural to try to ascertain whether the lower animals, whose organisation is simpler, manifested pathological phenomena, whether in fact one could observe in them cases of infection, cure, and immunity.

To work out this problem it was necessary therefore to work at it from the point of view of comparative pathology.

In the course of investigations into the origin of the digestive organs in the animal kingdom we were struck by the fact that certain elements of the organism which do not take any part in the digestion of food are nevertheless capable of seizing foreign bodies. This we imagined was due to the fact that these elements at one time shared in the digestive functions. I cannot go into this question now, but shall merely bring before you the general outcome of our investigations in this direction, viz., that the elements of the organism of man and animals possessed of individual movement and capable of englobing foreign bodies are merely the remains of the digestive system of primitive beings.

In certain of the lower animals, transparent enough for it to be possible to examine them alive, one sees in their interior a large number of tiny cells provided with mobile prolongations. The least injury to these animals is followed by an accumulation of these cellular elements exactly at the damaged spot. In little transparent larvæ it can be seen that the mobile elements, gathered together at the site of injury, often enclose foreign bodies.

These data, confirming on the one hand our views as to the origin of these migratory elements, suggested, on the other hand, that their aggregation in the neighbourhood of a lesion constituted a sort of natural defence of the organism. Means had to be devised to verify this hypothesis. At that time, now upwards of 25 years ago, I happened to be at Messina. I took to studying the floating larvæ of star fish, larvæ that were discovered for the first time on the shores of Scandinavia, and known as *bipinnarea*. They are big enough to allow of various operations, yet they are transparent enough to allow of their being watched under the microscope while still alive.

I introduced splinters into the bodies of these *bipinnarea*, and the next day I found a thick layer of mobile cells round the foreign body. The analogy of this phenomenon with what takes place when a man pricks himself with a splinter, followed by inflammation and suppuration, is very striking, with this difference, that in the larvæ of the starfish the accumulation of mobile cells takes place without the intervention of the blood vessels or nervous system, for the simple reason that they do not possess either. The accumulation must therefore be the outcome of spontaneous action on their part.

The process just described is, so to speak, the first step of inflammation in the animal world, but as met with in man and the higher animals this process is

almost always the consequence of the introduction of some morbid organism. This fact militates in favour of the hypothesis that the afflux of mobile cells towards damaged parts represents the reaction of the body against foreign bodies in general, and pathogenic microbes in particular. Looked at from this point of view the disease becomes a struggle between the morbid agent, the microbe from outside, and the mobile cells belonging to the organism. Recovery follows when the cells carry the day, and immunity is evidence of their possession of sufficient energy to prevent the intrusion of microbes.

This deduction required to be verified by exact observation and experiment, and fortunately man and the higher animals are not the only beings liable to infectious disease; indeed, these must have existed long before the appearance of human beings.

To confirm the accuracy of our hypothesis we had to discover a being belonging to the higher walks of animal life, small and transparent enough to be kept under microscopical observation, and also liable to microbial attack.

After various attempts in this direction it was found possible to study the course of an infection in fresh water animals commonly known as water fleas. A disease to which these tiny crustaceæ are liable is that caused by the minute organism which is peculiar in that it produces needle-shaped spores. When swallowed by the water flea, or *Daphne*, these spores readily pierce the intestinal walls and find their way into the body. Once inside the flea the presence of these spores causes an accumulation of mobile cells corresponding to the white corpuscles of human blood. A struggle takes place, sometimes the one, sometimes the other, remaining victorious.

These data constitute the basis of the theory which I will now proceed to formulate. Having established the basis of this theory of immunity, we had to apply it to higher organisms; in fact, to man. It was obviously impossible to resort to direct microscopical observation, so we were fain to have recourse to more complicated procedures combining the results of researches on the blood and organs removed from the body, and associating them by an intellectual process, a mode of reasoning that exposed us to manifold sources of error.

The investigation of various infectious diseases in man and the higher animals tended to confirm the results of observation of what takes place in the lower, transparent animals. In every instance in which the organism enjoyed immunity inoculation with microbes was followed by the accumulation of mobile cells, the white blood corpuscles in particular, which enveloped the microbes and destroyed them. These cells were distinguished as "phagocytes," i.e., voracious cells, while the function of immunity as a whole was called "phagocytosis."

It has been established that, as a general rule, in all cases of natural or acquired immunity, either by preventive vaccination or following an attack of the disease, phagocytosis was very active, while in fatal or severe cases of infection this phenomenon either did not take place at all, or was ill-marked. This rule was first demonstrated in animals inoculated with the bacillus of anthrax. When the anthrax bacillus is introduced beneath the skin of animals sensitive thereto, such as rabbits or guinea-pigs, the microbe lies free in effused liquid, in which there are few or no white corpuscles. When animals that have been immunised are inoculated, a very different state of things is observed. Within a short time the bacilli are seized by the white corpuscles, which promptly assemble at the site of introduction, and are destroyed, usually within a few hours.

Later on, the same rule was found to apply to a number of infective maladies, and was confirmed by the study of pathogenic microbes discovered after it had been formulated. In bubonic plague, for instance, whenever the organism proved refractory the bacillus was found to have been devoured and destroyed by the phagocytes, while in the fatal cases most of them were free in the body fluids, and multiplied *ad lib.* So far, we have not come across a single exception to this rule. It is true that Mr. Weil, of Prague, asserted that in cases of immunity to fowl cholera the refractory

organism defended itself against the threatened invasion by means other than phagocytosis, basing his belief on the impossibility of finding this microbe inside the white corpuscles of animals which, however, had resisted the disease. This exception is only apparent, and is to be explained by the fact that this excessively minute organism readily escapes recognition. Soulima has investigated this matter most carefully in my laboratory, and he has established beyond question that the usual law applies here as elsewhere.

The adversaries of the theory of phagocytosis held for a long time that the white corpuscles, and phagocytes in general, were only capable of seizing upon microbes that had already been killed by the humours, *i.e.*, by the blood plasma and effused liquids. No one however, defends this view at present, for it has been conclusively shown that the phagocytes do actually invest living microbes still capable of provoking fatal infection in organisms not possessed of immunity.

These results, which I have briefly stated, were only obtained after long years of patient observation and discussion. Many authorities still held to the ancient idea that white corpuscles were something inimical to health. Formerly, when suppuration took place, the pus being particularly rich in white corpuscles, and the microbes too small to be seen, it was supposed that these corpuscles themselves constituted the disease. When, later on, the presence of microbes was demonstrated within these cells, it was asserted that the white corpuscles provided food for, and assisted in disseminating, the infective agents, and the destruction of the latter was ascribed to the body humours.

The theory of the bactericidal action of the humours was evoked in opposition to the theory of phagocytosis.

The immune organism was credited with the power of destroying infective microbes without the assistance of the living cells. This view was based on certain well-known experiments, in which blood and blood serum taken from the organism proved capable of killing large numbers of infective microbes. Although almost from its inception this humoral theory of immunity had to face numerous grave objections, it secured many active partisans, and it received a special measure of support from Pfeiffer's discovery of the destruction of the comma bacillus in the abdominal cavity of animals immunised against the disease. In this instance the cholera bacilli met their fate not inside the phagocytes, but in the fluid exuded into the peritoneal cavity. For years it was asserted that this instance was no exception to a general rule, but was itself the general law of immunity. Nevertheless, after years of laborious investigation, it has been definitely established that the great majority of infective microbes cannot possibly be destroyed by the body liquids, and that the instance of the comma bacilli could be explained by their extreme fragility. It was asserted, on the other hand, that the destruction of the comma bacilli by the body fluids was effected by bactericidal substances that had escaped from the white corpuscles into the peritoneal cavity. In cases where the same microbe was introduced in regions where there were no pre-existing white corpuscles, the bacilli met this fate inside the phagocytes that had come to the rescue. Even in the abdominal cavity extra-cellular destruction of the comma bacilli could easily be avoided by preventing the white corpuscles opening and discharging their bactericidal contents. This experiment, which was long contested by various observers, was ultimately settled by Beil, of Prague. It may consequently be taken as proven that if the white corpuscles remain intact the destruction of the comma bacilli within the organism takes place inside the phagocytes.

Close scrutiny of the phenomena met with in immunity amply demonstrates the fact that phagocytosis is truly a defensive act on the part of the organism against infective agents. Several former partisans of the purely humoral theory of immunity subsequently rallied to the theory of phagocytosis, but with various important reservations, with the result that we had several intermediate theories, according to which the threatened organism brought every means at its disposal to bear—phagocytes and humours—immunity resulting from the destruction of part of the microbes in the plasma, while the more resisting were swallowed by the phagocytes.

In this defensive scheme the organism is supposed to employ two categories of bactericidal substances, some of them circulating in the blood fluid, passing thence into the exudation that forms round the microbes, while others only exist inside the phagocytes. The first act especially on the cholera vibrio, the typhoid bacilli, and their congeners, while the others destroy the anthrax bacillus, the pyogenic microbes, etc.

In conformity with the two different bactericidal functions of the organism, the nature of the substances that destroy the microbes is also assumed to be different. The humoral bactericidal substances are stated to be of a complex nature, comprising a substance which, though not directly injurious to microbes, renders them amenable to the action of the substance that kills them. These two substances have been baptised several times over. Ehrlich gave the name *amboceptor* to the preparatory substance, and *complement* to the one that destroyed the microbe. In order not to further complicate a question that is complicated enough as it stands, I shall adhere to these two terms, although I do not share the views of my illustrious *confrère* on the intimate rôle of these two substances.

Whereas formerly—that is to say, more than ten years ago—various authorities asserted that the bactericidal substance, properly so-called, although circulating in the blood, was nevertheless secreted by the white corpuscles, of late the contrary view makes itself more and more heard. They admitted readily enough that the complement had nothing whatever to do with the white corpuscles, having an entirely different origin. This view is based on numerous researches carried out by the aid of extracts of white corpuscles taken from the organism. With this object in view, we take an effusion very rich in these corpuscles, these are well washed to get rid of the liquid parts, and then they are killed by exposure to cold and left to macerate in normal saline solution. Extracts of white corpuscles thus prepared do not contain any complement capable of killing microbes, a statement which has been verified over and over again. This, however, does not warrant the conclusion that white corpuscles do not give rise to the complement.

In order to arrive at an opinion on this much-debated point, Dr. Lavidité and I set to work to investigate the bactericidal properties of white blood corpuscles. We found, to begin with, that when withdrawn from the organism, these cells are perfectly capable of enveloping and destroying microbes in large numbers. We made use of Denike's vibrios, something like the microbes of Asiatic cholera, and we had no difficulty in witnessing their transformation into granules inside the white corpuscles of guinea-pigs. This transformation took place promptly with vibrios that were impregnated with the amboceptor or preparatory substance, a change indicative of their destruction. The white corpuscles, therefore, possess within them a substance which acts exactly like the complement of the humours. Now let us see how it behaves in liquids which do not contain this bactericidal substance, and which contain a plentiful supply of white corpuscles containing the complement. All we have to do is to keep these elements for twenty hours, by which time we shall find that they have become absolutely incapable of effecting the transformation of vibrios laden with amboceptor. The corpuscles have had time to die, for the most part, and, this being the case, the vibrios remain intact.

This experiment, repeated several times over with the same result, shows that the complement in the white corpuscles is a highly unstable substance. It is certain, therefore, that prolonged washing, refrigeration, and maceration of the white corpuscles is amply sufficient to destroy the complement, and this is a reason for rejecting such methods of investigating the state of the bactericidal substances of the white corpuscles.

It must not be imagined that the action of the complement is only manifested during the life of the white corpuscles—that is to say, is a purely vital phenomenon. On the contrary, it is in all probability a chemical action, which changes according to the state

# IRISH POOR-LAW AND LUNACY INTELLIGENCE,

Being the Supplement to the "Medical Press and Circular."

WEDNESDAY, JULY 28TH, 1909.

**Notice to Correspondents.**

Poor Law Medical Officers and other subscribers to THE MEDICAL PRESS AND CIRCULAR are invited to make use of the facilities provided by the Management of the Journal for obtaining information on all matters connected with the Poor-Law Medical Service or the Medical Profession generally in Ireland.

The Editor will be glad at all times to receive letters or marked copies of newspapers dealing with matters of medical interest. All communications must be addressed to the Office of the Journal, 18 Nassau-street, Dublin, and should be delivered not later than Saturday morning to ensure attention in the issue of the following week.

**EVENTS OF THE WEEK.**

We report in another column the decision of Mr. Justice Johnson in certain cases brought before him at the Limerick Assizes, in which the Rathkeale Guardians had appealed against the decision of the County Court Judge in granting decrees to Dr. Hayes and Nolan for the recovery of fees for the examination of lunatics. The Judge reduced the fees in each case to one guinea, holding that the cases presented "no unusual difficulty." His Lordship thought himself well paid at a guinea in ordinary cases when practising as a barrister, and apparently thought no one else should be paid at a higher rate. We have no means of valuing Mr. Justice Johnson's services as a barrister, nor do we wish to suggest that he himself at all undervalues them. Nevertheless, he is not as much at home in medical as in legal work, and is not, therefore, quite competent to judge what sort of case is an "ordinary case," and what presents "unusual difficulty." We must emphasise the fact that no case of examination of a lunatic is an "ordinary case," and no case demanding the attention of a medical man requires more care, or demands greater responsibility of judgment. It is a serious matter to commit a man to an asylum as a dangerous lunatic, and medical men who have to certify in such cases should be paid for the meticulous care they have to exercise, and the responsibility they have to assume. The work is in no way comparable to that of the guinea barrister, who has not

responsibility either to the client or the public. Moreover, whatever Mr. Justice Johnson's custom may have been, we know few barristers who would be content with a fee of one guinea in cases requiring the care, caution, and knowledge, demanded from a medical man in the examination of an alleged lunatic.

**FEES FOR TEMPORARY SERVICES.**

At a recent meeting of the Carrick-on-Suir Guardians the Clerk read the following:—

South-Eastern Branch.

Irish Medical Association,

Portlaw, July 2nd, 1909.

At the meeting of the above body, held at Clonmel on June 2nd, the following resolution was unanimously adopted: "That in consequence of the refusal of the Local Government Board to sanction a greater amount than four guineas per week for temporary services in dispensary districts in cases in which exceptional circumstances make this amount insufficient remuneration for such services, the branch requests its members that none of them should act in such cases unless he previously receives in cash from the Relieving Officer such amount per day or per week, as would be reasonable expense for the work to be done until the Local Government Board amends its procedure. Copies of this resolution to be sent to each branch of the Association, the Chief Secretary, the Clerks of each Union, etc.

J. QUIRK, Hon. Secretary.

This Branch has adopted a sound plan, which ought to be followed by others throughout the country.

**GRADED SCALE IN SHILLELAGH.**

The Guardians of the Shillelagh Union have adopted a graded scale of salaries for their medical officers.

### TYPHOID FEVER, IN TIPPERARY.

A serious outbreak of typhoid fever has occurred in the Currahaba district of County Tipperary within the past couple of weeks. Some thirty or forty patients have been admitted to the Thurles Hospital, and fresh cases are still occurring.

### LUNACY FEES.

At the County Limerick Assizes a number of cases at the suit of Doctors Hayes and Nolan, the Medical Officers of Rathkeale and Shanagolden Dispensary Districts, against the Rathkeale Guardians, were heard before Mr. Justice Johnson. The cases were appeals by the Guardians from decrees given the doctors by the County Court Judge at the Rathkeale April Sessions for the amounts claimed by them for examining persons charged as dangerous lunatics who were committed to the Limerick Asylum within the present year.

His Lordship, after hearing the evidence of Doctors Hayes and Nolan, Mr. T. B. Naughton, Clerk of the Union; Head Constable Brosnan, Rathkeale, and Sergeant Davis, Ballingarry, said that as the cases were of great importance to the medical profession he would reserve judgment until Wednesday morning. At the opening of the Court on Wednesday, his Lordship said he had carefully considered the cases affecting the medical profession, and he entirely concurred in the judgment delivered by the Lord Chief Justice and Mr. Justice Wright in Dr. King's case, and entertained no doubt whatever but the expenses incurred previous to the committal of the persons charged should come out of the £2 in each of the cases in which the justices allowed the maximum sum. These cases presented no unusual difficulties to the doctors concerned; there was no danger of their being subjected to personal violence, and he was in favour of the opinion expressed by the Lord Chief Justice and Mr. Justice Wright in Dr. King's case, that one guinea would be reasonable remuneration, where no unusual difficulties presented themselves, and especially when the doctors had not to go beyond the police barracks in their district. His Lordship remarked that when practising at his profession he considered he was fairly well paid in ordinary cases when he received one guinea; and, no matter what the medical profession might think of his judgment, he was obliged to reverse the decision of the County Court Judge in all the cases, and allow the doctors one guinea to each case, both the appellants and respondents to pay their own costs, and he would allow no expenses to either side.

At the sitting of the Assize Court on Thursday, Mr. Kelly, B.L., mentioned to Mr. Justice Johnston that he had received a wire from one of the doctors concerned in the cases for medical fees for certifying lunatics, saying that he would like if his Lordship stated a case.

Mr. O'B. Kelly, B.L., said that could not be done after the decision.

His Lordship said similar cases may arise before the next Assizes, and his decision only applied to cases at the present Assizes.

Mr. Kelly intimated his satisfaction with his Lordship's reply.

### WESTPORT UNION.

#### CLARE ISLAND.

At the meeting of the Board of Guardians of Westport Union the following letter from the Local Government Board was read.

"The Local Government Board have given the Guardians' proposal careful consideration, and having regard to all the facts and local circumstances they are of opinion that a case has not been established to justify the appointment of a separate medical officer for the Islands of Clare and Inishturk, and that the islands in question should continue as heretofore to form portion of the Louisburgh Dispensary District.

"The Board, therefore, propose to sanction the appointment of Dr. James J. McGreal, who has been elected by the Guardians on the 13th May last, as Medical Officer of the entire Louisburgh Dispensary District, but they would suggest that the Guardians

should consider whether instead of paying him a salary of £150 a year to cover his dispensary duties, including a weekly attendance at Clare Island he should be paid a salary of £120 a year as dispensary medical officer, and allowed in addition £1 for each attendance given by him at Clare Island not exceeding £50 a year.

"There is a resident midwife on the island, for midwifery cases, and the medical officer is bound to attend with all due dispatch upon midwifery and other urgent cases as they arise there from time to time.

"A special meeting of the Guardians should be convened to deal with the suggestions as to medical officer's remuneration and his weekly attendance at Clare Island.

"I am, Sir, your obedient servant,

A. R. BARLAS, Sec.

The Chairman said they were asked to hold a special meeting to consider the suggestion that Dr. McGreal should be allowed £1 per visit to Clare Island, instead of £50 a year.

It was decided to adhere to the existing arrangement, allowing £150 for the entire district.

It appears from the report of Sir A. McCullagh that no sanitary accommodation for patients exists at any of the Dispensaries in Westport Union.

Dr. Maguire and Dr. Heneghan wrote stating that they would not approve of the recent Tuberculosis Notification Act being put in force in the Union, and the Board unanimously agreed not to put the Act in force.

### BALLINA UNION.

The Local Government Board has sanctioned the decision of Ballina Dispensary District, and issued a sealed order for the appointment of a second Medical Officer.

### THE URBAN COUNCIL AND THE WORKHOUSE WATER SUPPLY.

The Chairman said the committee went up to the Workhouse last Friday week, and before going up were buoyed up with the hope that they would find a mare's nest. They decided first to test the pressure outside the gate, and took a good deal of trouble in doing so, and the pressure only amounted to 7lbs., which was absolutely insufficient to supply even the basement of the Workhouse with water. Something would have to be done to get a proper supply of water. Dr. Macaulay told him none of the houses in Francis Street got a supply when the watering cart went out.

Dr. Macaulay holds that it is our first duty to scrape the main, and to do it if possible at night so as to give as little inconvenience as possible.

Mr. Chambers: But even with the scraping a seven-inch main is not sufficient to supply the town.

Chairman: However, we adjourned the scraping till the middle of September.

For years this totally inadequate Water Supply has been a scandal and grave public danger. For years the Guardians have been complaining and passing resolutions, at length the Urban Council summoned up sufficient courage to appoint a committee. Result, as usual, nothing to be done.

### RATHDRUM UNION.

At the last meeting of the Rathdrum Guardians, the first business taken up was the proposal to increase the salaries of the medical officers.

The Clerk read a recommendation of the committee as follows:—"The committee recommend that an immediate increase of £25 a year be granted to each medical officer who has five years' service; we do not recommend a retrospective scale."

The Local Government Board wrote that section 3 (2) of the Probate Duties (Scotland and Ireland) Act, 1888, enacted that all sums paid to the Board of Guardians of a Union pursuant to that Act shall be applied in aid of the poor rate, and therefore no portion of the Estate Duty Grant can be regarded as specially earmarked to recoup expenditure in respect of medical officers. The only fund to which these salaries are chargeable is that created by section 58 (1) of the Local Government Board (Ireland) Act, 1898, and under sub-

section 2 (a) (1) of that section, one half such salaries are payable through the county councils to the Boards of Guardians. A limitation to recoupment in respect of the Guardians' expenditure under all heads of sub-section 2 (a) was imposed, however by section (6) (1) of the Local Government Act, 1902, and the provisions of this latter section are always operating in the case of Rathdrum Union.

The Local Government Board wrote relative to the proposal of the Guardians to grant Dr. O'Keeffe, medical officer, Newcastle Dispensary District, an allowance of £30 a year until a residence is provided, and pointing out that Dr. O'Keeffe's outlay in providing house accommodation is only £30 a year, and that there did not appear to be any sufficient reason why he should be allowed £30 a year for house rent. If the Guardians considered his present salary inadequate to enable him to pay house rent they could deal with the matter in connection with the proposal to adopt a scale of graded salaries for the medical staff of the union.

The Chairman said the Guardians would be glad to hear any statement the doctors had to make.

Dr. Hamilton, Arklow, said he laid certain figures before the committee that day fortnight, but he was not quite sure of some of them, and he asked the clerk to correct them. He had gone to the trouble of looking up the Probate Duties Act of '98, and he had the figures that Mr. Manning got from the secretary of the County Council. In Rathdrum Union there were nine medical officers whose salaries were £120 each, which amounted to £1,080. Half of that was refunded, leaving £540 to be met by the Guardians in respect of salaries. But in addition to that under the Probate Duties Act 51 and 52, Vic. Cap. 63, a certain sum of money was apportioned to the poor-law unions to meet expenses under the Medical Charities Act, which included doctors' salaries and educational expenses. Their proportion for last year amounted to £788, and according to his reading of the figures the amount which they had to pay to the doctors was £1 13s. 4d. a year each. As a matter of fact in his (Dr. Hamilton's) opinion the guardians had to pay nothing to the doctors, but were actually making something by them (laughter, and applause). He hoped that was true (hear, hear). The increase would have to come out of the rates. The increase plus the present salaries the doctors were receiving would work out at about a halfpenny in the £, and if they were not worth that they were worth nothing.

Mr. Joseph Byrne—I would not like to give some of the doctors a halfpenny.

Dr. Hamilton, continuing, said that according to the present proposal by the time he would reach the maximum of £200 a year, Dr. Ryan would be high up in heaven (laughter); and by the time Dr. Ryan would receive the additional £40 a year he would be about 100 years of age (laughter). Even when the maximum salaries were reached the cost to the union would still be under 1d. in the £. The labourer was worthy of his hire. They were all Irishmen, and some of them natives, and they would all like to be able to live in their own country and not be going away to foreign countries. As a body the doctors were the worst paid public officials in the country. In the town he lived in the district inspector of police got £95 a year for a horse and car, but the medical officers got no such allowance.

Mr. Short—And they have far more important work.

Dr. Hamilton said in another year the medical officers' services would be State services. He was sorry for it, and voted against it at the Medical Congress. He would be sorry to part from the guardians. The salaries they would receive in future would be based upon the salaries the guardians gave them. As he said before he would be sorry to part from the guardians, but if they must part they would be glad to part with the best salaries they could get (loud laughter).

The Chairman said in the Gorey, Shillelagh, and Baltinglass Unions, the doctors were receiving increased salaries. There was no doubt the doctors' salaries were very low for the duties they had to perform. With regard to the statement made by a guardian that he would not give a halfpenny increase to some doctors,

he (chairman) said if a doctor was not doing his duty it was the duty of the guardian of the division to report the matter. The fault in that respect lay with the guardian, who was the only person the poor had to look to.

It was decided, on the motion of Mr. M'Grath, seconded by Mr. Carey, to ask the doctors to withdraw while the guardians were considering the matter.

The following doctors who were present then retired: Dr. Ryan, Dr. Taylor, Dr. Hamilton and Dr. Lynch.

Mr. P. J. Carey proposed that as the committee's recommendation did not seem to meet with the approval of the Board, that every doctor with over five years' service receive an immediate increase of £20 a year, and that he receives an increment of £5 after every five years until the maximum is reached.

Mr. Hagan seconded the proposition.

Several Guardians said at that rate the maximum would never be reached.

After some discussion, Mr. Carey agreed to amend his proposal so that the increment of £5 should be given every three years.

Mr. Ellison suggested that the increment every three years should be £10.

The Chairman suggested that they should split the difference, and make the increment £7 10s. every three years.

Mr. Carey refused to accept the amendment.

A show of hands resulted in the defeat of the proposal to make the triennial increase £7 10s.

Eventually Mr. Carey's resolution was passed by the majority of the guardians.

#### ATHY UNION.

At the meeting of the Athy Guardians a letter was read from the Local Government Board stating that the Board desired to inform the Board of Guardians of Athy Union that they have received the report of their Medical Inspector, Surgeon Colonel Edgar Flinn, relating to the inquiry on oath recently held by him into a charge of neglect of duty preferred by Mr. J. B. Alexander Bosanquet against Dr. J. Kilbride, Medical Officer of the Athy Dispensary District, in the case of children named Devereux. The Board considered that the explanation given by Dr. Kilbride was not unreasonable, and may be accepted. The complaint that the medical officer had been rough in his manner towards Devereux and his wife was not, the Local Government Board consider, proved by the evidence.

#### SPREAD OF SCARLATINA.

At the last meeting of the Rathdown Rural District Council a letter was received from Dr. Cahill, Medical Officer of Health in the Dundrum district, who wrote in reference to the epidemic of scarlatina, that parents were in the habit of allowing children suffering from "rashes" to go about without having consulted a doctor as to the nature of the rash. There was a prevalent opinion among the poorer classes that the child must be "real sick" if scarlatina is present, whereas the type of the disease most commonly met with nowadays was very mild, and led to little discomfort or apparent illness; Dr. Cahill suggested that a number of leaflets containing simple directions bearing on the subject should be printed and distributed in the district.

Dr. Usher, J.P., said that mild cases of scarlatina were very liable, unless the proper treatment was applied in due time, to become extremely serious cases. What should be impressed upon the public was that scarlatina was scarlatina, and had to be treated as such whether it appeared in a mild or an aggravated form.

It was decided to adopt Dr. Cahill's suggestion, and issue printed notices on the subject.

We are glad to see some of the rural councils taking steps in such a practical way to give instruction to the people.

#### SWORN INQUIRY IN NAAS.

The treatment of a man named Patrick Doyle, a native of Kilcullen, while an inmate of the Naas Workhouse Hospital, was the subject of a sworn

inquiry held by Surgeon-Colonel Edgar Flinn, Local Government Board Inspector, at Naas, on Tuesday. The inquiry was ordered on a complaint made by Thomas Doyle, a brother of Patrick, who died in the hospital on the 21st May last.

Thomas Doyle stated that the deceased complained to him when he visited him, that he had been put into cells for ten days and nights for breaking over the wall. Another allegation the deceased made was that the Master shortened his days by putting him in a cell when he was an hospital case, and spitting up blood.

The Master, Mr. Shiel, stated that the deceased came to the hospital as an influenza case, and was afterwards returned as suffering from phthisis. He then related the circumstances under which Doyle was placed in the cell.

#### AN AMBUSH.

About 8.30 on the evening of the 2nd February he ascertained that deceased was in Naas, and he was aware he had not got a pass. The porter, Constable Kenny, Wardmaster Hannan, and witness went to the boundary wall about 9 or 9.30, and waited there. After a short time the porter found Doyle in the act of getting over the wall, and witness asked him his name, which he gave as Thomas Johnston. Doyle was

searched, and they found on him two half-pints of whiskey, some tobacco, and 3s. 5d. in cash. He presented the appearance of being under the influence of drink, and witness went to the nurse in charge of the hospital, Sister Agnes, and told her of this, and she said he had gone out without leave, and that she could not allow him back into the ward. He was then put into the cell. The cell had no fireplace or window; it was about 80 yards from where there would be an attendant. There was a straw bed—in a tick—and there were bedclothes—two blankets. The cell was about 9 or 10 feet long by 4½ feet wide, and had a wooden door. Doyle was locked in the cell, and he (the Master) did not tell anyone to look after him specially for the night.

The Master was questioned as to why he did not put the man into the casual ward, where there was a fire, and the answer was that it being half-past nine the fire would be out. Further pressed on this point, the witness gave as a reason that Doyle was under the influence of drink. He would not have put him in the cell if he had thought he was suffering from lung trouble.

Dr. Coady, Medical Officer of the Workhouse, said considering the man was suffering from phthisis, he did not think it was wise to put him in a cell. He did not, however, consider the night in the cell had any ill-effects.

### THE DUBLIN INSTITUTE OF BACTERIOLOGICAL AND CLINICAL RESEARCH, LABORATORIES—21 LOWER ORMOND QUAY, DUBLIN,

of the white corpuscles. Here is an analogous instance in support of this view.

The great masses of living matter found in certain mushrooms, the "myxomycetes," are, like the white corpuscles, capable of enveloping and digesting foreign bodies in their vacuoles. The latter are filled with an acid juice which favours digestion, its reaction being easily demonstrated by presenting this living matter with fragments of blue litmus, which soon turn pink. Now, without killing the living protoplasm, the slightest damage by pressure causes the litmus to turn blue again, this being due to the living matter being permeated with an alkaline substance which, on the slightest injury, penetrates the vacuoles and neutralises the acidity. This is an example of a purely chemical reaction intimately associated with the life and integrity of living matter. It may be asked, however, why this action of the complement is so fugitive in white corpuscles, while it lasts so much longer in humours withdrawn from the organism, such as blood serum. The difference is believed to be due to the fact that the white corpuscles, in addition to the complement, contain still another anti-complementary body which prevents the action of the former, just as the myxomycetes, alongside of the acid juice, contain alkaline substances.

Without going further into detail it may be stated that white corpuscles are vastly more complex than they appear at first sight, and that the method of treating them *en bloc* for preparing extracts is about as coarse a method as if we were to crush entire mice or frogs in the endeavour to estimate their digestive powers.

As the outcome of experiments which cannot be gone into here we adhere to our view that the complement of the humours is derived from the white corpuscles. When these are slightly injured they allow the complement to escape into the liquid medium, whereas, if more seriously injured, they give issue to a substance that neutralises the action of the complement. We are enabled to quote well-established facts in support of this assumption, for instance, in an immune organism the white corpuscles of which remain intact, the vibrios do not undergo granular degeneration in the humours, and only assume the granular form inside the white corpuscles.

We are arguing in favour of the identity of the complements contained in the phagocytes with those of the blood serum. Do there exist, apart from the complement, substances exclusively and intimately bound up with the white corpuscles? No definite answer can be given to this question for the time being on account of the extreme technical difficulty of the investigation, but this appears to be highly probable as shown by the experiments carried out by Petterson and others in respect of *endolysines* (Petterson) or *leukines* (Schneider).

Independently of this delicate problem it is well established that the microbicidal property of the humours is limited to very fragile microbes, while that of the white corpuscles and of phagocytes in general, extends to all infective agents to which the organism is immune.

(To be concluded in our next.)

## ON CERTAIN ASPECTS OF MEDICAL JOURNALISM. (a)

By DAVID WALSH, M.D.,

Senior Physician, Western Skin Hospital, London, W.; Physician to the Kensington and Fulham General Hospital, &c.

THE medical journal of to-day is accepted by most of us as a familiar fact; but there is much in its history, as well as in its habits and its environment, that will repay discussion. By a process of specialisation it has evolved into a distinct species of that mass of ephemeral literature which we term modern journalism. Its characters are sharply defined. Amongst them it reports progress, not only at home, but also of the whole world, from China to Peru; it registers the ever-changing relations between medicine and the State;

(a) Address read by proxy before the Annual Meeting of the Association of American Medical Editors, Philadelphia, June 1st, 1909

it exposes the injurious methods of the charlatan, and in a thousand other ways protects the health of the community; it forms a central exchange, so to speak, for medical views and opinions; and, lastly, it records the domestic happenings of the great professional family, of which it is in many senses the guide, philosopher and friend.

But while it is true that the medical journal of to-day holds up the mirror to a world of wide activities, we cannot overlook the fact that it is a species of late development. It is emphatically an offspring of modern environment, conceived of the unceasing intellectual energy of mankind, born of the printing machine, rendered possible by the post office, and nurtured by the aid of a progressive profession.

### EARLY DAYS OF MEDICAL JOURNALISM.

The *Lancet*, the pioneer of medical journalism, first saw the light of day on Sunday, October 5th, 1823. It was issued weekly, at the price of sixpence, and consisted of some 30 crown-octavo pages. In its preface the editor says:—"It has long been a matter of surprise and regret that in this extensive and intelligent community there has not hitherto existed a work which would convey to the public and to distant practitioners, as well as to students of medicine and of surgery, reports of the Metropolitan Hospital Lectures." The contents of the new journal, however, were of a much more catholic nature than the foregoing remarks might suggest, for they included long criticisms of plays, table talk of a diversified nature, reports of criminal trials, general news unconnected with the profession, humorous anecdotes, and chess problems.

The readers of the *Lancet*, however, were evidently not dissatisfied, for we find that after a year's existence the editor was able to announce that "Our success has exceeded our most sanguine expectations." It is interesting to recall the fact that for the first ten years the *Lancet* "was a duelling ground for a series of fierce encounters between the editor and the members of the privileged classes in medicine." (a) At that period all the chief medical and surgical appointments were in the hands of a carefully organised clique, who did not hesitate to stigmatise the outspoken editor of the new venture as a literary pirate and a disseminator of moral garbage. The trouble did not end there, for in the first decade of his editorial experience Wakley was engaged in no fewer than ten law actions, six of which were for libel. In these latter a sum of £8,000 was claimed as damages, and an aggregate sum of £155 6s. 0½d. was awarded, while the costs were defrayed for the most part by public subscription. A great deal of interesting information regarding the *Lancet* can be obtained from the excellent "Life of Thomas Wakley," written by Dr. Squire Sprigge, who has lately succeeded to the editorial chair. The contrast between the *Lancet* of 1824 and that of 1909 is no less marked in quantity than in quality. The modest crown octavo of 30 pages has grown to 70 or 80 pages or more of handsome double quarto, with an equal number of pages of advertisement. The *Lancet* is read all over the world, and enjoys a princely income apparently.

The second oldest weekly medical journal is THE MEDICAL PRESS AND CIRCULAR, the Dublin editor of which is Dr. H. Jellett, of Dublin, while the London editorship is in my own unworthy hands. It appeared first in 1838 as the *Dublin Medical Press*, and was amalgamated in 1866 with a small London weekly, the *Medical Circular*. The journal was then called by its present name; it is of quarto size, published mid-weekly in London, and sold at fivepence. It has always been distinguished by a tone of fearless but impartial criticism, and it has lived long enough to see the accomplishment of many of the reforms advocated in its columns.

There is no need here to do more than mention the *British Medical Journal*, with its weekly volume of scientific, literary, and general editorial matter. This journal, which has probably the largest medical circulation in the world, is under the able direction of Dr. Dawson Williams, assisted by Dr. Frederick Taylor.

(a) "Life and Times of Thomas Wakley." By S. M. Sprigge, M.D. London: Longmans. P. 81.

Nor is there any need to allude individually to the rest of our medical journals, weekly, monthly, quarterly, special and general, many of them no less excellent in matter than in manner. During the past generation a good many such journals have come into existence, but not a few have passed away after a more or less brief sojourn upon the professional stage. The majority have owed their origin to some busy medical man, who has devoted his spare energies to that most fascinating of pursuits, the creation of a modern journal.

#### THE SUPPRESSION OF QUACKS AND QUACKERY.

One of the noblest crusades that could be fought by a medical journal has always seemed to me to be that against quacks and quackery. If the mission of scientific and practical medicine be to foster the health of the community, that function could hardly be fulfilled to better purpose than by exposing the fraudulent practices whereby and whereon the charlatan waxes fat at the expense of his fellows. From the outset of medical journalism this subject has been singled out above all others for editorial onslaught. It must be confessed, however, that this output of energy has not been hitherto attended with the success to which it is entitled.

British law is riddled with absurdities when it comes to dealing with unqualified medical practice. Provided he does not assume the title of doctor, and does not actually sell medicines, any quack may set up as a bone-setter, a cancer-curer, a specialist in the treatment of eyes, nerves, skin or any other part of the human body. If an unqualified person assume the title of doctor, he can be prosecuted under the Medical Acts. That offence, of course, it is easy to steer clear of, much more so, in point of fact, than the further offence of selling medicines, for which a prosecution may be brought under the Apothecaries Act. As a matter of fact, our Medical Acts are so badly drawn that they utterly fail so far as concerns the protection of the British public against quackery, and practically for many years past the only penal control in that direction has been through the limited powers conferred by the Apothecaries Act. There can be little doubt, nevertheless, that under the existing common law, apart from special Acts, a great deal might be done to check the evil. During the past few years the police have successfully prosecuted a few of our most notorious quacks. The charge by means of which they have laid these gentry by the heels is the extremely clear and simple one of obtaining money by false pretences. That method of procedure has been strenuously advocated for many a year in *THE MEDICAL PRESS AND CIRCULAR*, and in other medical journals. What we really want is some responsible central authority whose duty it shall be to prosecute all such offenders systematically and automatically, just as any other rogues are controlled. There must be something rotten in a system of criminal law administration which sends to prison a man as a vagabond, who has no visible means of subsistence, or who asks for alms when he is starving, but which at the same time permits a quack to extract money and to put his victims to unutterable, and it may be fatal, pain and misery, on pretence of curing their maladies. With a strong police administration to enforce the principle that a quack, like other persons, must abide by his published undertakings, and by his contracts, and must give proper value for money received, it is likely that, under such adverse conditions, this terrible evil of quackery would be speedily abated, if not altogether rooted up and cast into the fire.

Meanwhile, the evils wrought by proprietary nostrums and by bogus practitioners have been ruthlessly exposed, not only by the medical but by several lay journals. In spite of repeated exposure, however, the tide of successful quackery probably never ran higher than it does at the present moment. Of late a cry has been raised for more drastic methods, and most of all for that truly British forerunner of legislation, a Royal Commission. That instrument of State investigation is often singularly efficient in collecting facts and in educating both public and legislators as to the needs of any given case. It has been advocated for many years past in the columns of *THE MEDICAL PRESS AND CIRCULAR*, and has been forcibly laid before

the British Medical Association by Mr. Henry Sewill. That demand has been forestalled by one of our Colonies—to wit, New South Wales, which, in 1908, issued a monumental report detailing the results of a Royal Commission upon the sale of proprietary medicines. The official document in question must become a classic for all future reformers in that important field of work, more especially in the English-speaking world. America is concerned in this report almost as much as England, for quackery is ubiquitous, and, with the aid of the post office and the newspapers, scours the whole world in search of victims. One has only to glance through a few pages of that volume to realise the vast amount of fraud and cruelty inflicted upon the community by the charlatan, who is endless in his shifts and his trickery, as he is heartless beyond words in his greedy cynicism. Take, for example, the brazen effrontery with which one firm sends out all over the world for the treatment of drunkenness a remedy made up for the most part of raw and inferior spirit. Could anyone imagine a more reckless defiance of the ordinary rules of ethical conduct than to sell such stuff under such circumstances to persons trying to break away from that very poison? The incident reminds one of the famous phials, said to contain blue, yellow, and white electricity, which some years ago were introduced by an Italian Count and sold extensively in the United Kingdom and elsewhere for the cure of cancer and other diseases. These parti-coloured nostrums were taken up strongly by a leading English journalist, and by various members of the nobility. For a time it almost looked as if Society were to be divided into two classes, those who believed and those who did not believe in the claims of the Italian nobleman. At length the bubble was happily pricked by the publication of an official analysis, which showed that the phials, regardless of their colour, were one and all filled with water, pure and simple. Both drink curer and cancer curer, it may be noted, agreed in their high price, in their absolute disregard for the ways of ordinary morality, in their trust in the credulity of mankind, and, above all, in their single-hearted confidence in the virtue of advertisement.

In that last-mentioned point lies more or less the pith of the whole matter. Modern quacks and modern quackery, with their train of appalling evil, could not exist without the support of newspaper advertising. The money spent yearly in obtaining publicity for proprietary medicines and worthless methods of treatment is simply enormous, and until the lay Press will consent to relinquish that source of income, it seems well-nigh hopeless to attempt reform in other directions. This aspect of the question has been recognised in America, and not long ago a note in the *Journal* of the American Medical Association announced that the *St. Paul Pioneer Press* had decided to sweep its office clear of offensive advertisements. (a) At the same time, the proprietors appeal to the public and to medical men to support them in their attempt to publish a clean newspaper. It is to be hoped that the profession in America will do all they can to help forward so laudable an enterprise. Were the medical men of any civilised country to take up persistently the cause of the lay newspaper that refused quack advertisements, the fame and fortune of many a journal could speedily be made or marred. Our influence as a profession is exercised upon every class of society, and it is not unlikely that if medical men insisted upon the expurgation of objectionable advertisements from the public Press, that the proprietors and editors thereof would sooner or later find themselves compelled to fall into line with their views.

There is another weapon of attack against the quack advertisement evil. If the selling of secret remedies on the strength of claims that cannot be established constitute the offence of obtaining money under false pretences, then the newspaper which publishes the false statements must surely be guilty of joining in a conspiracy to defraud, and be thereby equally liable to public prosecution.

In the United Kingdom there is a strange lack of official machinery for the defence of the community

(a) *The Journal*, May 15th, 1909. P. 1599.

against quacks and quackery. It is not the business of the General Medical Council; it is not the business of the qualifying corporations (except in the limited instance of the London Apothecaries' Company); it is not the business of the police; and it is apparently only in extreme and rare cases the business of the Public Prosecutor.

The evil has existed since the dawn of accurate and systematic medical knowledge. Fresh parasites appear for every fresh branch thrown out from the parent stem of science. Your up-to-date quack is a shrewd fellow, ever on the look-out for a smart commercial application of the latest medical advances, be they radium, sinusoidal currents, or what not. As a rule, however, he trusts to some simple drug, which may be powerful, mild, or inert—it matters not to him which—but he gives it a fancy title and claims to cure therewith sciatica, epilepsy, locomotor ataxy, cancer, and any or every other disease, curable or incurable, that can attack mankind. At times he resorts to methods of such glaring absurdity that one would think they would not be able to secure a single customer. Yet such devices as metal rings for the cure of rheumatism, and socks for drawing the same disease out through the feet, are advertised year after year at a cost that could be defrayed only by a large and flourishing business connection.

Pretenders of this class spend large sums in advertising, but it is not easy to understand how any honourable man, as editor, can continue to circulate these misleading statements when once their real nature had been pointed out to him.

Our ancestors gave short shrift to some of the charlatans, for in the time of King Henry VIII. the President of the Royal College of Physicians of London was empowered by law to prosecute all persons in the metropolis who pretended to cure diseases without the proper qualification. That useful provision was suspended by the introduction of the Medical Acts of 1858, and, unfortunately, no efficient prosecutor was therein substituted. Our mediæval forbears recognised even at that comparatively early period of medical knowledge the necessity of excluding quacks, and the revival of so excellent a principle appears to be vital to the present protection of the public against the bogus practitioners and the vendors of worthless, dangerous and fraudulent nostrums who prey upon them by night and by day.

One reason why the quacks have hitherto escaped punishment as a whole is undoubtedly due to a peculiar sort of sympathy which exists in minds of a certain order towards bonesetters, herbalists, and other irregular practitioners. That feeling, however, has not saved the quack dentist from the clutches of the law. So stringently have the Dentists' Acts been administered of late in the United Kingdom that for an unqualified person even to advertise sets of artificial teeth or painless extractions is now a punishable offence, inasmuch as it it held to imply legal qualification. One magistrate said in so many words he thought it admissible for an unqualified man to exhibit a case of teeth and to put up his name, but nothing more. He fined an unqualified dentist £20 and 5 guineas costs for affixing a notice outside his place of business to the effect that he "was not registered under the Dental Act of 1878," on the ground that he thereby implied qualification elsewhere. On the whole, there can be little doubt that the day of the quack dentist is drawing to a close so far as the United Kingdom is concerned. That happy result is chiefly due to the campaign instituted by medical and dental journals, a fact that is encouraging in the campaign against the infinitely more nefarious and more deadly practices of the quack and the quack medicine proprietor.

Through all the tragedy of this unhallowed traffic with the health and the lives of mankind, the medical journals have maintained a firm attitude of condemnation. Who can doubt that one day the collective commonsense of mankind will confirm their view, and will drive out the unqualified medical pretender from their midst, just as in our own country they have practically driven out unqualified lawyers, dentists and veterinary surgeons? As a simple question of political economy, the sweeping away of quackery by the saving in the life and health of citizens, not to mention the

diversion of money from unproductive into productive channels, must infallibly add to and conserve the national wealth in a way that would speedily recompense the necessary disturbance of vested private interests.

#### "DE QUIBUSDEM ALIIS."

So much has been said about the pirates of medicine that little space is left for others that are the common-places of medical journalism. Amongst such burning topics may be mentioned the decline of the birth-rate, infantile mortality, the campaign against tuberculosis, infant teething, one-portal qualification, faith-healing, anti-vaccination, anti-vivisection, medical inspection of school children, and the notification of measles. Then there is the scientific side of the work, always an important matter. As every medical editor knows, many medical men who are highly skilled observers fail when it comes to the question of literary expression. Some authors resent the slightest alteration of their text, while others gratefully adopt any suggestions as to form, and it is sometimes hard to say which of the two is the more embarrassing from the editorial point of view. In one particular the editor requires to exercise the greatest care and prudence, namely, in the rejection of scientific communications. The medical world of to-day is apt to reject, more or less contemptuously, that which is new and heterodox, as it was when Harvey was given the cold shoulder for his views about the circulation of the blood. In some medical journals it is the custom to keep a sort of scientific censor, whose duty it is to determine whether any given article is to be accepted or otherwise. Although there is something to be said in favour of this plan, it nevertheless seems undesirable to run the risk of limiting the progress of medicine by the introduction of personal factors. Censorship of the kind should be applied sparingly. Of all things, scientific progress is the one that depends most upon vigorous breadth and freedom of mind. Science requires free trade in intellectual wares, and history has shown us again and again that discoveries of the utmost value have come from the least likely quarters.

A few words may now be said about the medical editor. One need hardly remark that it requires a man of peculiar gifts to fill that position successfully. It by no means follows that because a medical man has achieved a distinguished scientific and professional career he will necessarily make a good and capable editor. As a rule there can be little doubt that he should be engaged in some branch of active professional practice, as otherwise he is likely to lose touch with the complex world with which he has to deal. He should be well grounded in general principles, in order that he may view fresh advances in their proper perspective. Before he has long occupied the editorial chair, it will become clear to him that the large proportion of his professional brethren think that Nature has endowed them to a pre-eminent degree with the gifts and faculties required for discharging the duties of his position. The editor must be versed in the editorial side of his work, and be able to select suitable subjects for discussion and comment; he must keep a keen eye on reports, reviews, medical news, correspondence, and a number of other matters of current interest to his readers. Then it goes without saying that he must not disregard the business interests of his journal, or he will come into collision with the publishing side of his management.

One of the chief risks ahead of the medical editor is the highly technical nature of his proof sheets. To bring a medical journal to anything like perfection in this respect is to achieve no mean thing. One might fill pages with recollections of the havoc wrought by printers' errors; but it will suffice to give one in which a compositor made the editor say that a certain distinguished man had treated a subject in his usual "nonchalant" way, whereas the real epithet was "trenchant."

A passing word may be given to the poet who plies the editor with doggerel upon every conceivable subject, in season and out of season. His emotional nature becomes unduly elated if his verses are published in small print at the end of the journal, and he waxes sarcastic, or even stops his subscription when his rhymes are rejected. The varieties of this par-

ticular phase of the disease *cacoethes scribendi* may be classified by some authority on mental alienations, and it is in that case to be hoped that he may be at the same time successful in providing a cure for what has hitherto proved a distressing, and, in most cases, a hopeless malady.

In conclusion, it may be remarked that the interests of medical journalism, like those of medical science, are cosmopolitan, and America has built up a system of medical journals of which the English-speaking world may well be proud. Whatever the future may have in store, we may at all events be sure that the medical journals of America, no less than of the United Kingdom, will worthily uphold the traditions of a great and noble profession.

## OPERATING THEATRES.

### ROYAL FREE HOSPITAL.

OPERATION FOR CARCINOMA OF THE RECTUM.—MR. J. P. LEGG operated on a man, æt. 65, who had been admitted on account of passing blood and slime in his motions. Since the summer of last year he had been suffering from constipation, but from time to time had attacks of "diarrhoea," the latter being chiefly due to passage of mucus. Since February, 1909, there had been blood in the motions, never in any great quantity, but usually some appreciable amount. During this time he had lost weight, but otherwise he was in good health. On examination per rectum, a large crateriform ulcer was found, occupying the posterior and left walls of the rectum; the anterior and right walls were free of disease. The ulcer extended a couple of inches up the bowel, and the lower margin of it was just inside the sphincters, about  $\frac{1}{4}$  in. from the skin of the anus. The bowel above the ulcer was healthy, and there was no stricture; moreover, the parts were movable on the deeper tissues, and no enlarged glands could be detected in the hollow of the sacrum. The edges of the ulcer were raised and hardened; the base was irregular and nodular, very friable, and bled easily. Nothing abnormal was detected in the abdomen; the liver was not enlarged, and he had no urinary symptoms. On July 3rd left inguinal colotomy was done, the loop of sigmoid being brought to the surface through the rectus muscle, which was split for the purpose for a distance of 2 in. in the direction of the fibres of the muscle. One stitch was passed through the mesentery, and the upper and lower ends were fixed to the angles of the parietal incision. On July 11th the sigmoid was opened, and subsequently all fæces were passed by the colotomy opening. In order to clear that portion of the bowel between the anus and the colotomy opening of any fæcal material or mucus, it was washed out by means of an irrigator, the nozzle being placed in the lower segment of bowel at the colotomy opening, and a soft tube passed per anum enabled the fluid to flow freely away and wash out this segment of bowel. The object of this proceeding was to have the rectum as clean as possible at the time the excision was done. On July 15th the patient was again anaesthetised and placed in the left lateral position, the buttocks being raised on a firm sandbag. A median incision was made from the anus to the lower end of the sacrum, the coccyx, being clear of its muscles, was removed, and the dissection continued till the rectum was exposed in the upper part of the wound. Next an incision was made all round the anus, and the lower part of the rectum was separated by dissection chiefly with scissors from the prostate in front, and the ischio-rectal fossa laterally; the insertion of the levator ani into the rectum was divided, and the separation of the rectum continued in an upward direction, taking care to keep as far away from the bowel as possible, and yet not to injure the bladder. After a little while it was possible to pull down the rectum, so that it could be severed a couple of inches above the upper limit of the growth. To enable this to be done, one or two vessels and bands of fibrous tissue passing from the front of the sacrum required division; the peritoneum was not opened. After the bowel had been completely freed, two clamps were placed on it, and it was divided between them.

The cut margins of the opening in the upper portion of the rectum were then united by two layers of sutures. The first layer, which was put in before the clamp was removed, passed through the whole thickness of the bowel wall, and the second row consisted of two or three interrupted sutures which invaginated and buried the first line of suture. Two drainage tubes were placed in the wound, one at the upper end just below the sacrum, and one at the lower end of the incision, which was then closed with interrupted sutures.

Mr. Legg said that in considering the question of operation in such cases as this one, the first part to consider was whether the patient's symptoms were such as to indicate either a palliative operation alone, or whether it was possible to rid the patient of his disease. In this patient the latter course was possible because the disease was apparently limited to the rectal mucous membrane, and had not infiltrated the surrounding parts, and there was no evidence of secondary growths elsewhere. Having decided on a radical operation, the next thing for consideration was the method of operation, and perhaps the most important point was where to place the new anus, and Mr. Legg had very little doubt that in the majority of cases an artificial anus in the left iliac region was the best. It was placed in a convenient place for the patient, and by splitting or separating the muscular fibres of the abdominal wall, a certain amount of control was very often obtained, especially if, in doing the colotomy, care was taken that a good spur was formed. With a sacral anus such a control was not usually possible. There is often also some prolapse of the bowel, and an anus in the sacral region was not nearly so convenient from the point of view of the patient's attention to his bowels, and keeping himself in a comfortable state. Moreover, it was more easy to fit a belt or other instrument in the left iliac region than in the sacral. In this patient, the lower margin of the growth being so close to the sphincter, it was obvious that this must be destroyed in the removal of the rectum, so that here no question arose of being able to bring down a cut upper end of the rectum and suturing it to the normally placed anus, and in many cases where this is feasible the amount of control over the motions is not perfect; therefore, Mr. Legg thought that for these reasons it was generally desirable to do a preliminary colotomy some days before the removal of the rectum. Another advantage of such a colotomy was that the wound left by the excision not being contaminated by fæcal material passing over it, healed more satisfactorily and in a shorter time. The colotomy should always be done into the highest part of the sigmoid, which should be opened, in the absence of symptoms such as vomiting or abdominal distension, in about a week's time. It is only necessary to make the opening sufficiently large to allow the contents to escape freely, and when the colotomy is acting satisfactorily (which is usually in from four or five days to a week), the removal of the rectum and growth may be done; thus, on the average, this will be ten days to a fortnight after the colotomy has been performed. The method of excision of the rectum which should be employed is determined by the position of the growth. When the latter is low down, the operation he had just performed gave a very satisfactory exposure of the parts, and was really a combination of the perineal and Kraske's operation, the coccyx only being removed. The method of completely closing the cut lower end of that portion of the rectum left behind was of great value, and prevented the large wound becoming infected. It was safe to do this, as the upper end of this portion of bowel was patent at the colotomy, and any secretion or fæcal material which might accumulate in this loop would be washed away by means of irrigation. Mr. Legg also pointed out that this case showed the necessity of examining digitally all cases of rectal disease, for this patient had been treated for some months by one medical man with medicines without any such examination, and it was only because he was not improving that he consulted a second doctor, who at once made such investigation and discovered the presence of the carcinomatous growth. It was only when one got these patients in

the early stages of their disease that it was possible to do a radical operation; hence the necessity of rectal examination in cases of chronic diarrhoea or constipation.

## TRANSACTIONS OF SOCIETIES.

### ROYAL SOCIETY OF MEDICINE.

#### OBSTETRICAL AND GYNÆCOLOGICAL SECTION.

MEETING HELD JULY 8TH, 1909.

The President, Dr. HERBERT SPENCER, in the Chair.

A SHORT communication on a

CASE OF NON-OVARIAN PELVIC DERMOID TUMOUR

was read by Miss FRANCES IVENS, M.S.

She pointed out that dermoid tumours originating in the pelvic connective tissue, non-ovarian in origin, are apparently of infrequent occurrence, and that she had only been able to collect 29 reported cases.

Gebhard, when commenting on the rarity of these tumours, points out their tendency to be of a somewhat simpler structure than the highly complex ovarian dermoids, hair and teeth being of infrequent occurrence.

Their origin is uncertain, and symptoms when present have been chiefly due to pressure on adjacent pelvic organs. Repeated attacks of pelvic inflammation have usually occurred. The case recorded by the author was that of a married woman, æt. 26, nulliparous, who was admitted to the Liverpool Stanley Hospital complaining of severe pelvic pain. It caused her great pain to sit down, and also during defæcation: she had suffered, but to a less degree, from attacks of a similar nature during the past seven years. A fixed, tender fluctuating swelling, the size of a goose's egg, was felt high up in the left fornix, and was thought to be a pyosalpinx or ovarian abscess. A few days later some substance, like thick matter, was said to have been passed per rectum. Laparotomy was performed, and the tumour was then found to be beneath the peritoneum and in front of the rectum, and to have no connection with the uterus or appendages. The peritoneum over it was incised, and the tumour shelled out and removed entire. No drainage was employed. On examination of the cyst it was found to contain a buttery material of an apple-green colour and very offensive odour, and the cyst wall, which was thick, presented at one point a softened area where it probably had intermittently communicated with the rectum. The cyst was lined with granulation tissue, from which all traces of epithelium had disappeared. The patient, who exhibited some alarming symptoms indicative of toxæmia for the first few days, ultimately recovered, and left the hospital well.

Dr. G. E. HERMAN said that he had, in a lecture published in *The Clinical Journal* of August 22nd, 1900, p. 277, recorded a case of a pelvic dermoid not ovarian, which suppurated whilst the patient was recovering from an uncomplicated ovariectomy. In a paper on "The Suppuration and Discharge into Mucous Cavities of Pelvic Dermoid Cysts," published in vol. xxvii. of "The Transactions of the Obstetrical Society of London," 1885, p. 254, he had collected a number of cases, some of which he thought were certainly not ovarian.

Mr. ALBAN DORAN desired to know Miss Ivens' opinion about the origin of the dermoid. It was not probable that the dermoid elements arose from displaced ovarian tissue, but it seemed very likely to be the homologue of the dermoid cysts occasionally found in the abdomen of men, as in Ord's case recorded in the 63rd volume of the "Medico-Chirurgical Transactions," where the tumour was closely related to the bladder and rectum.

Dr. F. H. CHAMPNEYS said that he had seen one similar case. The tumour lay between Douglas's pouch and the sacrum, was about the size of an orange, and had no apparent connection with either ovary. It came into notice first during labour,

caused considerable obstruction, and the patient died of sepsis.

The PRESIDENT (Dr. Herbert Spencer) asked whether it was possible that the tumour was a degenerated fibroid. He had met with a case in which he had enucleated a tumour per vaginam from Douglas's pouch. The pulsatious contents led him to think it was a dermoid. He had to open the abdomen for oozing, and found that it was a fibroid which had grown from the back of the lower segment. Examination of the tumour with the microscope showed it to be a cystic fibro-myoma. He had several times observed the solidification of the contents of degenerated fibroids (from clotting), and this he thought might be mistaken for the setting of the liquid fat of a dermoid.

Miss IVENS regretted that she had not seen the paper by Dr. Herman on the suppuration and discharge into mucous cavities of dermoid cysts of the pelvis, and mentioned that her communication referred entirely to retro-peritoneal dermoids. In answer to Mr. Doran's question respecting the origin of the cyst, Miss Ivens said she believed it to be derived from foetal remnants, probably the post-anal gut or projection of the hind gut behind the proctodeal depression. Replying to the President that no hair or skin lining could be seen, she said that the diagnosis rested on the greasy character of the contents, which though liquid on removal, solidified to the consistency of butter on cooling. After repeated attacks of suppuration extending over a period of seven years, it was unlikely that the original lining of the cyst could be demonstrated.

PRESIDENT'S VALEDICTORY ADDRESS.

Dr. HERBERT SPENCER then delivered a valedictory address to mark the close of his term of office as President of the Section.

### CENTRAL MIDWIVES' BOARD.

The Central Midwives' Board met on Thursday last, July 22nd. There were present Dr. Champneys, in the chair, Dr. Stanley Atkinson, Mr. Golding-Bird, the Hon. Mrs. C. Egerton, Sir George Fordham, Miss Paget, Sir Wm. Sinclair, and Mr. Parker Young.

Inquiries had been received as to quarantine to be imposed on pupils coming from hospitals of the Metropolitan Asylums Board. It was agreed that the following conditions should be observed: (a) Adequate disinfection before leaving a fever hospital; (b) a period of quarantine lasting one week to safeguard patients against incubation of a fever in the nurse.

A letter signed "G. P.," appearing on pp. 1153 and 1154 of the *British Medical Journal* of May 8th, 1909, complaining of the conduct of a certified midwife, was further considered. A letter on the subject from the Secretary of the Medical Defence Union, and a statement by the writer of the letter signed "G. P.," with the observations of the Executive Officer of the Local Supervising Authority thereon, were also considered. The Board decided that as the midwife has already been reprimanded by the Local Supervising Authority for the error she committed, and as in other respects the statements of "G. P." do not appear to be substantiated, no further action be taken in the matter.

Miss Jane Holland Turnbull, M.D., B.S., was placed on the list of Supernumerary Examiners. Arthur Knight Gale, M.R.C.S., L.R.C.P., was approved as Teacher. It was agreed that the request of the Devon and Cornwall Training School to hold the written examination locally be granted.

### OPHTHALMIA NEONATORUM.

A long discussion and a sharp division of opinion resulted from the consideration of another recommendation. The Local Government Board sought the Board's opinion as to precautions favoured by the London County Council in order to guard against the recurrence of ophthalmia neonatorum, and inquired in particular "whether the use by the midwife of a weak solution of nitrate of silver is advisable for infants born of mothers suffering at the time of birth from a vaginal discharge." The Committee recommended a reply in the following form:—"(a) That in the opinion of the Board it would not be advisable to order

midwives to drop any fluid into the child's eyes as a matter of routine; (b) the dropping of antiseptic chemical fluids into the conjunctival sacs by midwives in cases of suspicion of gonorrhœa, etc., is a practice to which the Board does not object where the midwife has received proper training, but the Board does not pledge itself that nitrate of silver is always the most suitable form of application."

On the discussion of Section A, Sir WILLIAM SINCLAIR at once expressed his absolute opposition to a proposal which he believed would result in serious harm, morally and socially. He moved, and Mr. PARKER YOUNG seconded, an amendment to omit the concluding words "as a matter of routine."

Miss PAGET pointed out that the broad effect of the amendment would be to necessitate the revision of the whole of the teaching of midwives, a contention which she supported by quoting from the regulations of several leading hospitals and from a number of midwifery text-books. It was very confusing to midwives, she urged, to be taught to do things which they were afterwards forbidden to do.

Sir WILLIAM SINCLAIR retorted that the facts adduced by Miss Paget afforded a strong argument in favour of the Board issuing a text-book of its own. On a show of hands the amendment was defeated.

The second part (b) of the recommendation was next considered, and some minor amendments were introduced after further protests from the minority, Sir WILLIAM SINCLAIR declaring that he would not be a party to a proposal which displayed ignorance alike of pathology and practice.

Mr. PARKER YOUNG moved a final amendment to omit section b, contending that by it the Board would be setting up two classes of midwives. By four votes to two this amendment was also rejected.

When, however, the CHAIRMAN put the same section as a substantial motion, Dr. ATKINSON expressed the view that they were bound to give weight to the opinions so strongly urged by Sir William Sinclair, and, to the Board's general amusement, the motion failed to obtain any support. Sir William and Mr. Parker Young duly recorded their votes against it, and the section which had been the subject of so much amendment and discussion was accordingly excised altogether.

A further recommendation of the Committee dealt with the subject in a more general way, and it was decided, with the object of minimising the risk of the occurrence of inflammation of the eyes in new-born children, to amend Rules E 14 and E 19, and, on the Privy Council's authorisation of those amendments, to issue a leaflet to midwives in explanation of the alterations. The draft of that document was approved with some changes after Miss PAGET had urged, on behalf of the midwives, that a really full and complete leaflet should be sent out.

The next general meeting of the Board will not be held until October 7th.

## SPECIAL REPORTS.

### ANNUAL MEETING OF THE BRITISH MEDICAL ASSOCIATION.

Belfast, July 26th, 1909.

[FROM OUR SPECIAL CORRESPONDENT.]

SIR WILLIAM WHITLA, M.A., M.D., LL.D., J.P., the President-Elect of the British Medical Association, was born in Monaghan in 1851, and educated there and in Queen's College, Belfast. He graduated in Medicine with highest honours and a gold medal, and afterwards had the degree of M.A. *hon. caus.* conferred upon him by the Royal University of Ireland, and in 1905 he received the high honour of the degree of LL.D. *hon. caus.* from Glasgow University.

He was appointed Physician to the old Royal Hospital, Belfast, in 1882, where he soon distinguished himself by his success as a teacher, and when, in 1890, Dr. Seaton Reid retired from the chair of Materia

Medica and Therapeutics in Queen's College, there could be no question as to the fitness of Dr. Whitla to succeed him. He is now Senior Physician to the Royal Victoria Hospital, the successor of the old Royal Hospital, and is also Consulting Physician to the Ulster Hospital for Children and Women, and to the Belfast

SIR WILLIAM WHITLA, PRESIDENT-ELECT.

Ophthalmic Hospital. Other posts which he either holds or has held are Senator in the Royal University, Examiner in Glasgow, the Victoria, and the Royal Universities, President of the Ulster Medical Society, President of the Ulster Branch British Medical Association, President of the Irish Schools' and Graduates' Association, and Senator in Queen's University, Belfast.

Notwithstanding the claims of a large consulting practice and the duties of his many posts, Sir William Whitla has found time to write, and has attained marked success as an author. His "Materia Medica and Therapeutics," first published in 1882, is now in the eighth edition, and his "Dictionary of Treatment," published in 1892, has run into four editions, not only in England, but also in America and China.

The Ulster Medical Society owes to Sir William Whitla a deep debt of gratitude, for through his generosity the Society possesses a most comfortable and commodious home, with rooms for meetings, committees, library, and amusements, in the Medical Institute. This was built entirely at his own cost by Sir William Whitla, and opened by His Excellency the Lord Lieutenant (Lord Dudley) in 1902. When the honour of knighthood was conferred by His Majesty at his Coronation on Dr. Whitla, the medical profession of Belfast and Ulster generally received the news with genuine pleasure, and as the premier medical knight of the city he worthily maintains the honourable traditions of the profession. When it was decided to invite the British Medical Association to meet in Belfast, he was unanimously chosen as President-Elect. He assumes office on Tuesday, 27th inst., and, judging from the programme, he will establish a record for open-handed Irish hospitality.

#### GENERAL ARRANGEMENTS.

AFTER an interval of twenty-five years, the British Medical Association is again meeting in Belfast, and many and marked are the changes that have occurred since the last meeting. The President then was the late Dr. James Cuming, and the numbers attending

were only 563. The Association has increased greatly since then, and the numbers attending the annual meetings have increased proportionately. This year it is expected that nearly a thousand will register, and as about four hundred ladies will accompany them the preparations for local hospitality have to be on a generous scale. All the sections are accommodated in Queen's College, which is a great convenience and saving of time to those who move about from one to another, and all the necessary offices are also in the College. The exhibition of instruments, drugs, etc., is in the exhibition hall, which adjoins the College grounds. The representative meeting is most comfortably housed in the Assembly Hall, Fisherwick Place, where also the Presidential Address will be delivered. Academic dress is to be worn on three occasions—at the President's Address, the Lord Mayor's Reception in the Town Hall on Thursday night, and at the Ulster Branch Reception in the Botanic Gardens on Friday night. His Excellency the Lord Lieutenant and Lady Aberdeen have accepted invitations to many of the meetings and social functions, the former being an Honorary Member of the Association since the Montreal meeting in 1897.

#### THE SECTIONAL MEETINGS.

Of the fifteen sections, nine are presided over by outside men and only six by local men, so that Belfast cannot be accused of being greedy in making the arrangements. The sections and their presidents are as follows:—Medicine.—Professor Lindsay, Belfast. Navy, Army and Ambulance.—Fleet-Surgeon Lloyd Thomas, R.N. Obstetrics and Gynaecology.—Dr. John Campbell, Belfast. Ophthalmology.—Dr. J. Walton Browne, Belfast. Pathology.—Professor Symmers, Belfast. Pharmacology and Therapeutics.—Professor Ralph Stockman, Glasgow. Anatomy and Physiology.—Professor Sherrington, Liverpool. Dermatology and Electro-therapeutics.—Dr. Wm. Calwell, Belfast. Diseases of Children.—Mr. Harold Stiles, Edinburgh. Haematology and Vaccine Therapy.—Sir Almoth Wright, London. Hygiene and Public Health.—Dr. Louis Parkes, London. Laryngology, Otology, and Rhinology.—Dr. St. Clair Thompson, London. Psychological Medicine.—Dr. T. Outterson Wood, London. Surgery.—Professor Sinclair, Belfast. Tropical Medicine.—Dr. C. W. Daniels, London.

Special interest attaches to the section of Haematology, which is being inaugurated at this meeting, and as the President is recognised as a "first-rate fighting man," and the assailants of his theories are many and fierce, blood is likely to be shed. In many of the other sections the discussions promise to be interesting. The section of Dermatology will discuss "The Uses of Radium"; the joint sections of Public Health and Laryngology will discuss "Diphtheria Infection"; the Ophthalmic section will discuss "The Workmen's Compensation Act and Eye Injuries," and the Obstetrical Section, the report of the Ophthalmia Neonatorum Committee, lately published.

From the point of view of the man in the street, undoubtedly the most interesting discussion will be that to be held in the section of Medicine on Thursday, when Dr. Clement Dukes, of Rugby, will open a discussion on the medical aspects of athleticism, and many men of note in the medical world will take part. Among the visitors to the meeting are Professor Fuchs (Vienna), Professors Sonnenburg and Greef (Berlin), Drs. Depage, Delsaux, Jacobs, and Bordet (Brussels), Professor Fehling (Strassburg), Professor Sanfelice (Naples), Drs. Wickham (Paris), Calmette (Lille), Delavan (New York), Cullen (Baltimore), Gordon Byers (Montreal), and a number of Colonial delegates from all parts of the Empire.

#### MEETINGS ALREADY HELD.

The Representative Meeting, which comprises about 150 representatives of divisions of the Association, and which sits in private to deal with questions of medical politics, ethics, etc., began its sittings on Friday last, and continued them on Saturday and Monday. The question of advertising was discussed, and the following resolution was passed:—"That it is the professional duty of medical authors of articles in medical journals to co-operate with the proprietors and editors of those journals in preventing any improper use of

such articles for the purposes of advertisement." The medical inspection and treatment of school children was discussed, and one learned to realise some of the difficulties which would arise if the Act were adopted in Ireland, when it is so troublesome in England.

The Representative Meeting takes its work very seriously, and sat till 10 o'clock on Friday night, but adjourned at 5 o'clock on Saturday to allow the members to go out of town for the week-end. Two excursions had been arranged, one to Portrush and the other to Newcastle, Co. Down, and most of the members availed themselves of one or the other. Unfortunately, the weather was far from good, and unless it clears before the end of the week the outdoor entertainments will be sadly interfered with. There are not so many private garden parties as usual on the programme of entertainments, but the receptions at hospitals are much more numerous than usual. The Royal Victoria, the Mater Infirmorum, the Abbey Sanatorium, the Forster Green Sanatorium, are all giving afternoon receptions on Tuesday, Thursday or Friday afternoons, while Wednesday is reserved for the President and Lady Whitla, who are entertaining the whole Association and many of the public as well at a garden party at Lennoxvale, their beautiful home in the outskirts of the city.

## CORRESPONDENCE.

### FROM OUR SPECIAL CORRESPONDENTS ABROAD.

#### FRANCE.

Paris, July 23rd, 1909.

#### COMA OF DIABETES.

IN diabetes, there exist different varieties of coma, but the most important, and even the only important, is that attended with acetonuria.

As soon as a diabetic patient becomes somnolent, as soon as his breath smells of sweet apple, active treatment should be prescribed: drastic purgatives, large doses of bicarbonate of soda (one ounce daily).

Injections of a solution of bicarbonate of soda into a vein have been proposed by Stadelmann in confirmed coma, while M. Lepine employs this method with success in the premonitory period. No one, says he, would believe, without seeing it with his own eyes, the facility with which patients, in the above condition, support an intravenous injection of two quarts of a warm isotonic solution of bicarbonate of soda containing about five drachms to the quart. The two quarts were injected in three-quarters of an hour. The results were very satisfactory; the threatening symptoms disappeared, and during weeks and months the patients were free from acetonic accidents.

When the patient is in the coma, the chances of a successful issue are very slight; yet in some cases temporary improvement has been obtained by these injections.

Instead of injecting the liquid into a vein, some suggested injecting it into the cellular tissue, but this practice cannot be recommended as bicarbonate of soda employed in this way has been known to produce phlegmon or even gangrene.

In order to favour combustion of the toxic products, inhalations of oxygen have been prescribed in the premonitory period of coma. Such treatment may be useful, and in any case it can do no harm.

#### ASTHMA.

The treatment of asthma is always delicate and difficult. Dr. Monncorge, of the Mont-Dore, has recently published a *résumé* of his experience of twenty years in the treatment of this affection.

The patient should be placed in a sitting posture with the head high, all clothes loosened, the window opened in a well lighted room as obscurity increases the anguish of the dyspnoea.

The usual powders and cigarettes will be tried while pyridine which diminishes the cerebro-spinal reflectivity, and increases the secretions, will be allowed to evaporate in the room (a teaspoonful in a saucer placed on the floor in a corner of the room and renewed two or three times a day).

Dry cupping, mustard poultices, foot and hand baths, find their indications.

As to internal remedies, it is preferable to forego them if possible; if not, the treatment will vary according to whether it is a case of spasmodic seizure or of catarrhal asthma.

In the spasmodic phase, antipyrine as a moderator of the nervous system may be tried, or sulphate of quinine, fifteen to twenty grains a day. Hippo may also be useful as an emetic.

As to iodide of potassium, if the patient has never taken any, a large dose of 40 or 50 grains a day may frequently arrest the attack. If, on the contrary, the patient has been in the habit of taking iodides, a large dose may be tried for one or two days, and if no improvement is noticed, the iodide of potassium should be completely abandoned. In cardiac and renal complications it is counter indicated. Secondary treatment consists in opium for the cough, chloral for insomnia, bromide of potassium for the general nervous excitement, digitalis for renal insufficiency, etc.

In this same spasmodic form, where the asthma is no longer dry but humid, atropine may be given with advantage.

Once the spasm overcome and the catarrhal period set in, recourse should be had to emollient inhalations, balsams, terpine, etc. In some cases small doses of tartar emetic are useful:

Tartar emetic, 1 gr.

Water, 4 oz.

A teaspoonful twice a day at meals.

Dietetic régime is important: absolute milk diet for patients strong enough to support it; at the same time warm diuretic drinks. In weakly patients: eggs, milk, potages, a little bordeaux, but no square meal should be permitted even where the appetite might call for it; the stomach should not be loaded nor a long digestion imposed.

#### SNEEZING.

If sneezing is sometimes a salutary act, freeing the respiratory tract, it can become dangerous as a means of contamination, while in persons suffering from heart disease or those of plethoric disposition, spasmodic rhinitis may be attended with evil consequences. Several means have been recommended to arrest the spasmodic effort, some of them belonging to family records, but the easiest and perhaps the surest, according to Dr. Champeaux, is gentle massage of the frontal region with the palmar face of the fingers of each hand by passing them from the temples to the median line of the forehead and always in this sense; the little movement should be practised several times until the person is relieved. A stranger's hand is better than that of the patient (?).

In any case the method is easy and within the reach of all.

#### GERMANY.

Berlin, July 23rd, 1909.

At the Freie Vereinigung der Chirurgen, Hr. Neumann spoke on the DIFFERENT FORMS OF DISTURBANCE OF THE CIRCULATION OF THE MESENTERIC VESSELS, of which, after the manner of Sprengel and his followers, he distinguished four varieties—hæmorrhagic infarct and anæmic gangrene, anæmic infarct and hæmorrhagic gangrene—according to whether artery or vein is affected alone, or whether the chief trunk of the one or the collateral branches of the other are occluded. As illustrations, he showed a number of patients and preparations, amongst them an enormous thickening of the mucous membrane and muscular tissues, with a corresponding narrowing of the calibre of the bowel, from which, however, one got the impression that the way had been paved for a spontaneous recovery. He considered resection of the bowel implicated, as the operation of choice in such cases.

Hr. Braun had experimented on animals in regard to ileus, and had observed that an excessive secretion quickly took place in the part of the bowel above the constriction. Filling of the abdominal cavity with blood went hand in hand with this. The centre of blood pressure at first remained uninfluenced, until at

last terminal paralysis of it took place more or less suddenly. This was purely asphyxic or anæmic; it was not at all of a toxic nature. Large quantities of blood serum from such animals injected into other animals were absolutely harmless. The conclusion he drew from this was that treatment by opium was justifiable to a certain extent, as it had an influence on the over-filling of the abdominal cavity with blood. A good effect on the blood-pressure centre was observed from saline infusions and adrenalin, but it was not maintained.

Hr. Berkofsky had collected the cases of

#### GANGRENE OF THE BOWEL

that had been met with at the Friedrichshain Hospital during the past ten years. There were 61 cases of gangrenous hernia, and 20 cases from other causes. The operation of choice in the case of hernias had been primary resection; bringing the bowel forward and wrapping it in iodoform gauze had been quite given up, or was only used very exceptionally, and always with a fatal result. In gangrene the furrow of constriction also was always resected, never sutured over. For anastomosis of bowel Murphy's button was mostly used; the peritoneum was always sutured, but the remaining abdominal wound always left open. The mortality had been 32.6 per cent. Of the 20 cases of gangrene of the bowel without hernia, 15 had been operated on, of whom 10 died. The bowel contents above the gangrene were not removed. The results had been identical, whether local or general anæsthesia had been made use of.

Hr. Neumann showed an elderly woman with tumour-like infiltrations of the skin. Although the first impression was of sarcoma, the tumours really consisted of lymphocytes, especially of the eosinophile kind. The disease was distinctly getting worse, and so far had defied all treatment.

He then described a method of procedure that had done him good service in the treatment of perforated ulcer of the stomach. From the point of perforation he led a drain into the duodenum for purposes of nutrition; this was conducted outwards by a sleeve formed of omentum. In doing this the omentum was fixed over the point of perforation, and later, when the drain was removed, it served as a covering. The patient recovered, and remained free from trouble. He described further a case of ileus caused by constriction by the much-doubted mesenterio-mesocolic ligament, that ran from the base of the mesocolon of the sigmoid flexure to the attachment of the mesentery.

At the Medical Society, Hr. Halberstaedter discussed the

#### ÆTIOLOGY OF TRACHOMA.

As a member of the syphilis expedition to Java, he had ample opportunity of studying the disease. Examination of the secretions from the eyes of patients gave no results. He then rubbed the secretion on to the eyes of anthropoid apes; sometimes this was followed by redness and swelling, but not always. Implantation of a piece of excised follicle was never successful. In the scrapings from the cornea inoculated he always found characteristic cell inclusions, the various forms of which corresponded with varied stages of development. He found the same forms in human trachoma, but only in recent cases. In older cases, such as conjunctivæ that had been damaged by the trachoma, he had never found them.

#### AUSTRIA.

Vienna, July 23rd, 1909.

#### RELATIONS OF GLANDULAR SECRETIONS.

FALTA again brought this subject before the members of the Gesellschaft der Aerzte in the form of a criticism of Rudinger's experimental results, which he obtained from injections of infundibulin, etc.

In the case of starving animals it was found that adrenalin and thyreoidin acted principally on the transformation of albuminoid substances, while the infundibulin, or pituitin, increased the nitrogenous equilibrium without producing any poisonous phenomena. No increase of carbo-hydrate transformation could be observed. Adrenalin acted principally on the liver, not only in mobilising carbo-hydrates, but in forming them also. Thyreoidin

and infundibulin according to the experiments of Bolaffio and Todesko act powerfully on the transformation of lime and magnesia. Adrenalin on the other hand stimulates the changes of phosphorus potassium and sodium. On the pancreas and epithelial bodies there seems to exist opposite actions, as adrenalin influences the phosphorus bodies in the pancreas, while thyroïdin and infundibulin inhibit calcium changes. Priestly found that uric acid and the allantoids were increased by the use of adrenalin. Bertill found that injections of adrenalis produced a neutrophile leucocytosis with a disappearance of the eosinophile cells. Falta thought these glands might be divided into accelerators and retarders. In the former group he placed thyroïdin, adrenalin, and infundibulin, all acting on the heart and vessels, while the infundibulin and thyroïd greatly influence the metabolism.

Between the accelerators and retarders there is another group of substances that act on the chromofin system and pancreas which influence the metabolism of carbohydrates. The secretion of the thyroïdea and the epithelial bodies of the gland seem to be antagonistic; if the latter be extirpated and an electric current applied it will be found to be hyperæsthetic, but if the former be destroyed and the epithelial bodies left intact the opposite will be found to obtain. Early experiments proved a difference between thyroïdea and pancreas, as dogs from which the glands were removed could not be made glycosuric by the injection of adrenalin. The cachexia strumipriva is characterised by the dominating inhibition of the peripheral nerves as well as the vegetative nerve system. From this action another classification has arisen, sympathico-tropen, as adrenalis, and automo-tropen, including thyroïd and infundibulin; but to meet this nervine arrangement system hormone or general stimulator has been applied to adrenalin. It is evident from these complex actions that we are still using compounds, with a complex arrangement. The transformation of carbohydrates, according to experiments, is necessary to supply nourishment to the heart, nerve system, and muscles, as well as the breathing apparatus which is done through the medullary impulse on the sympathetic nerves, which are again regulated by the autonomy nerves.

Schwarz said he had experimented with a pressed extract of the pituitary body of horses, which he had injected into guinea pigs, weighing  $1\frac{1}{2}$  to 2 kilogrammes, and in all cases obtained polyuria—two hypophyses cerebri to each animal. This was accompanied with diarrhœa, but Borchardt's glycosuria was hardly ever present. He concluded that the pituitary body had no specific action on the animals, *i.e.*, any particular organ, and that the increased blood pressure of the suprarenal body was quite absent.

Schiff said he had experimented with the pituitary body for the last twelve years, and concluded that there is a striking analogy between the hypophysis cerebri and the thyroïd gland in the human being; both decidedly increase the elimination of phosphorous substances. This elimination is greatest from the bowel, as the urine is not much affected by them. It has also been proved beyond doubt that this phosphorus is in combination with lime, clearly proving that its source must be of an osseous nature.

#### MYCOSIS FUNGOIDES.

Riehl showed a patient, æt. 29, with erythrodermia desquamating, and in places there were accumulations the size of walnuts discharging from below the hard crust which in places formed tumours of a degenerative character. This secondary change was very unusual.

## FROM OUR SPECIAL CORRESPONDENTS AT HOME.

### SCOTLAND.

#### THE NEW PROFESSOR OF SYSTEMATIC SURGERY, UNIVERSITY OF EDINBURGH.

A MEETING of the Curators of Edinburgh University was held on the 21st, for the purpose of electing a successor to Professor Chiene. The Curators present

were the Lord Provost, Lord Stormonth Darling, Lord Dundas, Principal Sir William Turner, and Counsellors Brown, Dobie, and John Murray. After careful consideration of the qualification of the various candidates, the names of Messrs. Hodsdon and Alexis Thomson were selected, and after further deliberation, Mr. Thomson was unanimously elected. The Curators resolved to meet again on the 29th inst. for further consideration with reference to the vacancy in the Chair of Anatomy, caused by the death of Professor Cunningham.

Mr. Alexis Thomson is 43 years of age, and was educated at the High School of Edinburgh, the Realschule in Hanover, La Villette in the Canton de Vaud, the University of Edinburgh, and subsequently at the London Hospital. He became a Bachelor of Medicine at the age of 21, and was awarded a gold medal for his M.D. thesis four years later. He was appointed Assistant Surgeon to the Royal Infirmary at the age of 29, and has had long experience and success as a teacher, a high record as a scientific worker, and a wide reputation as an operative surgeon. For thirteen years he delivered qualifying lectures on surgery, and only discontinued systematic teaching in order to have more time for research. He has conducted classes in operative surgery for students for fifteen years, and for post-graduates for two years. As Assistant Surgeon he has had sixteen years' experience in clinical teaching and has been entrusted by the managers and University authorities with the duties of both Professor Annandale and Professor Chiene during their temporary absence from duty. When the Deaconess Hospital was founded in 1893 Mr. Thomson was appointed Surgeon, and has held that post ever since. He is an examiner in surgery for the Royal College of Physicians, and was for a number of years Inspector and extra examiner at the Apothecaries' Hall in Ireland. Mr. Thomson has an extensive acquaintance both with foreign literature and with foreign methods. He has worked at, or visited, the classes of Schede in Hamburg; Von Bergmann, Hahn, and Korte in Berlin; Durante and Alesandri in Rome; Terrier, Albarron, Kirmisson, Tuffier, Hartmann, and Walther in Paris; Lauz in Amsterdam; Schœemaker at the Hague, and has also visited Montreal, Toronto, New York, Baltimore, Boston, Chicago, and Rochester. He has represented the College of Surgeons at the International Medical Congress at Berlin, at the meeting of the American Medical association in Boston, and at the French Congress of Surgery in Paris. He is a member of the International Society of Surgery. Mr. Thomson has published a great deal of valuable scientific work, bearing especially on surgery and surgical pathology. His monographs on Tuberculosis of Bones and Joints, on Neuroma and Neurofibroma, are both well known and recognised as of permanent value. For the past six years he has acted as joint editor of the *Edinburgh Medical Journal*. It remains only to add that Mr. Thomson is one of the most popular members of the medical profession in the city, and that his election has received almost universal approbation. A host of well-wishers congratulate him on his well deserved success, and confidently anticipate that his election will strengthen the University and the Medical Faculty.

### EDINBURGH UNIVERSITY GRADUATION CEREMONIAL.

THE annual graduation ceremony took place on Friday, July 24th. Only two LL.D.'s were conferred, the recipients being the Right Hon. George Wyndham, M.P., D.C.L., the Lord Rector of the University, and Madame Curie, Paris. Great disappointment was felt that, on account of illness, Mme. Curie was compelled to receive the degree *in absentia*. After the ordinary degrees had been conferred and the prizes distributed, Sir Thomas Fraser delivered the customary address to the graduates. He said this was the third occasion on which the duty had fallen to his lot, and that the gratification he felt at having so long a period of office vouchsafed to him was tempered by the loss of so many old friends and colleagues—in the Senatus there was only one and in the Medical Faculty no member remaining of those who held office when he became a Professor. He made reference to the various

changes which had occurred during the year—to the death of Professor Cunningham, the resignations of Professors Chiene and Kirkpatrick, and then passed on to speak of the leading features of University life since he last addressed the graduates in 1894. He was gratified to find a remarkable advance had taken place in the output of research work, for which he had appealed in his speech in 1894. Former apathy had given place to an active policy of encouragement of original work, and this had resulted in a very high standard characterising many of the M.D. theses during recent years. Since 1894 £31,719 had been presented to the University in aid of research, irrespective of the grants of the Carnegie Trustees or from the McKie Endowment Fund. The important result was that higher education by research was now so firmly established in the University that it was no longer necessary to advocate its claims. As a further direction in which the University might develop, and thereby increase her usefulness, he suggested specialisation. The advance of knowledge in many lines, and in the comparatively restricted subject of medicine, had been so great as to exceed the capacity of any individual, and the time was now ripe for extending that recognition to other separate subjects, which had already been granted to medicine, surgery, midwifery, and gynaecology. He suggested that diplomas in special branches of medicine might be instituted—for instance, in mental diseases, in nervous diseases, in ophthalmology, in diseases of the ear and throat. The courses of instruction would generally extend over nine months. In the meantime the University had instituted a diploma for specialised study in the subject of tropical diseases only; there was equal need for a similar diploma in Public Health (additional to the existing degree in Science and Public Health).

The graduation ceremonial was concluded by the benediction being pronounced, and thereafter the graduates filed on to the platform and shook hands with the Senatus. The usual luncheon in the University Union followed, presided over by Mr. J. J. M. Shaw, M.A., M.B., President of the Union.

## LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

### THE ASSOCIATION OF MEDICAL DIPLOMATES OF SCOTLAND AND THE MEMBERSHIP QUALIFICATION.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Those who hold the licentiatehip of the Royal College of Surgeons of Edinburgh, either alone or conjoined with the Glasgow or other Scotch qualifications, have for a long time laboured under a disadvantage in practice owing to the lack of a membership qualification. The matter has for several years engaged the earnest attention of the Association of Medical Diplomates of Scotland, on whose behalf I venture to ask the insertion in your valuable columns of the following communication addressed to the Edinburgh College.

I am, Sir, yours truly,  
DAVID WALSH, M.D.,  
President A.M.D.S.

Welbeck Street, London, W.,

July 21st, 1909.

To the President and Council of the Royal College of Surgeons of Edinburgh.

Gentlemen,—The Association of Medical Diplomates of Scotland beg respectfully to remind you of a petition formally presented to your President and Council in 1905, praying that steps be taken, by extension of Charter, if necessary, to secure an additional diploma of membership for your ancient College. It was shown in that petition that the lack of an intermediate qualification between the licentiatehip and the fellowship imposes a serious social and professional handicap upon your licentiates in various parts of the United Kingdom and elsewhere, inasmuch as the majority of their competitors hold the membership of other Colleges. The Council of the Association of Medical Diplomates of Scotland, therefore, as

representing the interests of Edinburgh Diplomates in all parts of the world, would be glad to learn whether the Council of the Royal College of Surgeons of Edinburgh have taken any further steps in the matter. If nothing has yet been done they would venture to ask if there be any likelihood of this most important, and, in their opinion, most salutary change being considered seriously by the Council of the College.

It need hardly be said that the Council of the Association would most willingly co-operate with the College in any way that might lead to the desired end. They presume the College will hardly require any further proof of the popularity of the proposed change than that afforded by the petition already formally lodged with the College—a document that was signed by many hundred of fellows and licentiates.

In conclusion, we venture to urge that the institution of the diploma of membership must infallibly lead to a great increase of the popularity and the usefulness of our ancient College: nor could it fail to establish a fresh bond of union between the College and its diplomates in all parts of the world, at the same time re-awakening old memories, interests and associations: while it would add to the material prosperity of the College for many years to come.

Awaiting the honour of your further reply to the considerations set forth in our former petition,

We have the honour to remain, on behalf of the Association of Medical Diplomates of Scotland,

Yours faithfully,

(Signed),

DAVID WALSH, M.D., President.

SKENE KEITH, M.D., Hon. Treasurer.

P. H. PARSONS, L.R.C.S. and P.Ed., etc.,  
Hon. Secretary.

### THE ANTI-VIVISECTION CONGRESS AND ARCHDEACON WILBERFORCE.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—When a man in the position of the Venerable Archdeacon Wilberforce makes a statement about the moral conduct of any person or group of persons, it naturally receives the implicit belief from the general public which is due to the reputation of its utterer. No matter what the modesty of the Archdeacon, and no matter how humbly he may view the important position which he has attained and his own merits, he cannot be ignorant of this fact. Knowing therefore his advantages as a maker of statements, he must from a sense of moral responsibility weigh his words, and it is inconceivable to think that he would publicly state not alone what he knows to be inaccurate, but—which is a very different thing—what he does not know to be accurate. It is, therefore, elemental that when he states that no greater cruelties are perpetrated in the world than those done in *some* physiological laboratories (the italics are mine), he must know the laboratories to which he refers. Further, he admits that there are *some* English laboratories which are exceptions (again the italics are mine), and therefore until he, so to speak, separates the sheep from the goats, he is lending himself to an attempt to throw a stigma on all. Surely the Archdeacon does not think that this is right, and that it is honourable to use his great position to make the innocent suffer with the guilty. It is inconceivable, and if he will accept an anonymous hand to help him from an anomalous position I venture to invite him to answer the following questions in your columns lest his inexplicitness should cause the weaker brother to offend to a greater degree, and to consider that his cause is entitled to the support of inaccuracy.

My questions are as follows:—

(1) Are any of the physiological laboratories, in which the "greater cruelty" is perpetrated, situated in the British Isles? If not where are they situated?

(2) In either event, what are the grounds on which he considers he is justified in using the adjective "greater" as applied to cruelty?

(3) Can he of his own personal knowledge apply the term cruelty to the operations performed in any laboratory?

(4) If he can, and if such laboratory is situated in

his own country, does he not consider it his duty to denounce it by name, regardless of the consequences to himself?

The Archdeacon has placed himself in a position which he cannot occupy with honour until he has proved his statements, and from which he cannot retreat except after confession of his error as public as was his sermon. His statements, if true, call for his further action. If they are untrue they serve only to bring discredit on the teachings of his church whose doctrines inculcate charity, the care of the sick, and the spread of truth because it is truth.

I am, dear Sir, yours truly,  
DOCTOR OF MEDICINE.

#### NORMYL TREATMENT.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—If one of the 150 doctors who, according to Mr. Cecil Chapman, "are customers" of the Normyl Treatment Association, will perform the duty incumbent upon him, and will bring before one of the medical societies a description of the cases he believes to have been successfully dealt with by the treatment, there cannot be the least doubt it will be proved that there exists no scientific basis for confidence in the efficacy of the remedies. If any one of the 150 had anything like scientific proof, he would need no urging to take this course. It may be possible to produce a number of cases that have left off drinking after the Normyl treatment, but, before accepting the results as due to the cause assigned to them, a good many facts will need establishing. We shall first need a critical diagnosis of the nature of each case. Many persons taking alcohol to excess give it up when the mental or physical pain from which they have been suffering is assuaged, perhaps by suitable moral influence or by medical treatment. These are very different from the cases of moral obliquity of infinite variety discoverable among drunkards and dipsomaniacs, and from the cases in which the nervous system, brain, and spinal cord have suffered alcoholic degeneration. Mr. Chapman says that one ingredient in the Normyl medicines defies the attempts of analytical chemistry to identify it. It can, at any rate, be separated, and its powers of causing physiological reaction of any kind be determined. If it could neutralise the mental and physical causation of even a small class of cases, there would not be the least difficulty in raising much more than £20,000 for its purchase; if it could cure drunkenness arising from half-a-dozen of the many more distinct causes it would be miraculous. The whole thing is a delusion, and if it is not complimentary to Mr. Cecil Chapman and his medical and philanthropic colleagues to repeat this, I am sorry. Let them take steps to submit the remedy to a scientific tribunal, so that, if established, suffering humanity throughout the world may participate. In every civilised country there exist scores of scientific workers who will eagerly examine any new treatment of disease offering the least claim to their consideration. If they all ignore the Normyl treatment, it is no doubt for the sufficient reasons which men of science, but not philanthropic amateurs, are easily able to recognise.

I am, Sir, yours truly,  
MEDICAL TEMPERANCE REFORMER.

July 23rd, 1909.

#### THE FERMENT TREATMENT OF DISEASE.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In the leading article on the above in your issue of July 21st it is stated that I am carrying out investigations in the laboratories of King's College Hospital. It is at King's College, not the hospital, at which my investigations are being pursued.

My period for work having terminated at the Imperial Cancer Research Laboratory, and being anxious to continue work in the direction of investigation of the blood in cancer, to which side of the question in relation to the treatment of cancer by trypsin and to the tryptic or anti-tryptic index under different conditions I drew attention in a paper of mine, published in the MEDICAL PRESS AND CIRCULAR of July 17th, 1907, Professor Halliburton very kindly afforded me facilities for work in the Physiological Laboratory of King's College, London.

Lest there be any misconception on the point, perhaps you will allow me to say that your article, above referred to, was written entirely unknown to me, though I feel bound to confess that it would have been strange indeed if no one had replied to criticism in the lay press, obviously on my work.

I am, dear Sir, yours truly,  
J. A. SHAW-MACKENZIE.  
Green Street, Park Lane, W.,  
July 23rd, 1909.

### MILITARY & NAVAL MEDICAL NOTES.

**GENERAL HOSPITALS IN CASE OF WAR.**—The arrangements for establishing general hospitals throughout the country in case of war are now as complete as can be expected, and the Mobilisation Section of the War Office possesses a record of every town hall, church, or large building throughout the country suitable for conversion into a general hospital of 520 beds (20 for officers). The Red Cross has given every help in the compilation of information necessary for the efficient mobilisation of the Territorial Hospital personnel and materiel, and the list of medical officers available on mobilisation fills seven closely-printed pages of the Army List. The Advisory Council of the Territorial Nursing Service has also assisted in the preparation of a large list of nurses available on mobilisation.

**THE OFFICE OF DIRECTOR-GENERAL ARMY MEDICAL SERVICE.**—An important leading article appeared in last week's issue of the *Army and Navy Gazette* on "The Future Director-General Army Medical Service." It discusses the question of extensions of service being granted to officers in high rank, and the disadvantages arising therefrom. In this case it has become well known that an extension is about to be granted to Surgeon-General W. L. Gubbins, whose retirement was due on the 26th inst., with a view to his succeeding the present Director-General when he gives up office at the end of the year. In future it is proposed to make it a rule that every officer appointed Deputy Director-General at Headquarters shall, in course, succeed the Director-General when the vacancy shall occur.

**THE OFFICE OF ARMY MEDICAL INSPECTOR.**—The Inspector of Army Hospitals, when the appointment was first made, was placed under the Inspector-General of the Forces. This now ceases, and the Medical Inspector is part of the War Office staff.

**THE RETIREMENT OF ARMY MEDICAL OFFICERS.**—It is very unfair that such difficulties are placed in the way of retired Army medical officers re-employed obtaining privilege leave. Every man working year in and year out needs relaxation for a month or so. As a rule, very little sympathy is shown by administrative medical officers to retired-pay executive officers. It is unjust that a retired military medical officer should have to provide a *locum tenens*.

**BLACKWATER FEVER.**—It is stated in an Indian paper that the main conclusions of Dr. Bentley and Captain Christophers, Indian Medical Service, as a result of their investigations in connection with blackwater fever in the Dooars, is that this malady is due to continuous attacks of malaria, and is not a separate disease. The remedy for it is to diminish malaria amongst both Indians and Europeans by quinine prophylaxis under expert advice. Captain Christophers is now investigating malaria in the Punjab, and Dr. Bentley is conducting a similar special inquiry at Bombay.

**ROYAL ARMY MEDICAL CORPS.**—The following promotions and appointments were officially Gazetted on Friday last:—1st Highland Field Ambulance.—J. D. Fiddes, M.B., to be Lieut., June 10th. 2nd North Midland Field Ambulance.—R. M. West, M.D. (late

Captain, 5th Northern General Hospital, Royal Army Medical Corps), to be Lieut., June 9th. 1st Wessex Field Ambulance.—Lieut. A. W. F. Sayres, to be Captain, June 13th. 5th Northern General Hospital.—Capt. R. M. West, M.D., resigns his commission, June 9th. 3rd Southern General Hospital.—Officers whose services are available for mobilisation:—A. L. Ormerod, M.D., to be Captain, July 10th. Attached to Units other than Medical Units.—Capt. C. K. Bowes, M.D., resigns his commission, June 15th. For attachment to Units other than Medical Units.—L. D. Bailey, to be Lieut., June 19th.

## REVIEWS OF BOOKS.

### HANDBOOK FOR ATTENDANTS ON THE INSANE. (a)

THIS trusty guide needs no recommendation from us, for its reputation has, in the past quarter of a century, been solidly established. It is but a truism to say that no one who undertakes the charge of an insane patient, whether in an asylum or elsewhere, should be without it, and the sphere of its usefulness is by no means confined to asylum attendants. The present edition differs from the former ones especially in containing a good deal of advanced knowledge, particularly concerning the structure and physiology of the nervous system. It might be doubted whether much of this knowledge is not irrelevant for the present purpose, or even misleading, on account of the false perspective thus given. For instance, it is hard to see the relation between the subject of the different layers of nerve cells in the cortex, or of the intimate structure of Pacinian corpuscles to the practical care of the insane. Still, any knowledge is better than none, and, pending the arrival of the happy day when the subject of pathological psychology reaches England from the countries which have done so much valuable work in this domain, perhaps anatomy is *faute de mieux* as good a subject as any other to teach asylum attendants.

### MENTAL DEFICIENCY. (a)

WE welcome the appearance of this book for many reasons. Mr. Tredgold's researches on the subject are well-known and highly appreciated. The subject is one of great importance, and too much neglected. Finally, the author has given his knowledge in a readable form, and it may at once be said that the book constitutes, perhaps, the best text-book on the subject in the English language. All aspects are considered, the clinical, pathological, and sociological. It is not the place to deal here with questions of detail, but we desire to call attention to a defect of the book which we trust will be remedied in a future edition—namely, the absence of reference to German research, which has throughout been practically ignored. When by far the most accurate work emanates from Germany, this is a grave fault in a book that aims at being broadly inclusive and is otherwise of a most practical and instructive character.

### ON SYMPTOMS AND THEIR INTERPRETATION. (a)

IN these days of laboratory research purely clinical methods are apt to be overlooked, or, at all events, relegated to a back seat, so to speak. It is, therefore, with great pleasure that we welcome Dr. Mackenzie's efforts to revive the old bedside observation method of diagnosis, feeling sure that if this were more assiduously practised at the present time, much good would result. The views put forward by the author are the result of an inquiry extending over a period

of more than twenty years. He starts with the assertion that medicine has not attained that position in science which ought justly to belong to her, and at the same time he insists on accuracy of observation. "An inquirer should keep his mind ready to review his most cherished beliefs," is a piece of very good advice which many workers would do well to follow.

After attempting to classify the symptoms of disease, the writer goes on to consider the great symptom of pain in all its varied aspects, and especially what he calls visceral pain. The importance of increased sensibility of the external body wall in relation to diagnosis is carefully discussed. The various organic reflexes come in for very full consideration, while a chapter is devoted to the laws determining the nature of the reflex symptoms. The rest of the book is of a more practical nature, and is certainly of a most highly interesting and original character. After telling us how to make a preliminary examination of the patient, Dr. Mackenzie takes up the various systems and organs from a symptomatic point of view. Here he is at his best. Nothing could be more instructive than, say, his remarks on the locality of pain in gastric ulcer, on gastric symptoms in cholelithiasis, or on the bearing of symptoms on prognosis. The book is evidently the result of much painstaking and repeated observation; it is eminently practical, and will be found stimulating to read and easy to assimilate. It reflects the spirit of a medical age which is practically decadent, but in which, nevertheless, much valuable work was done.

### NEURASTHENIA AND NEUROSES. (a)

THIS little volume constitutes a sequel to the author's interesting "L'Education Rationnelle de la Volonté" that was published a short while ago. It has one great merit—namely, that it vigorously denounces the great Weir-Mitchell dogma that still lies so heavy on the land. It is, therefore, a book that especially needs to be read in Anglo-Saxon countries. To anyone who has made a scientific study of the psycho-neuroses it is a convincing proof of the ignorance of our profession on the subject that this dogma should so long have been accepted. Levy, in a masterly way, points out how irrational is the conception that, once the diagnosis of hysteria or neurasthenia is made, all that remains to be done is automatically to put the patient to bed, to isolate and over-feed him, and all will be well. In no group of conditions does individual treatment vary more from patient to patient. Levy rightly holds that a large number of such cases are better treated when still at work, or, at all events, engaged in some useful occupation.

Further than this the book has no value, for, as the author appears to be unaware of the recent epoch-making work of the German school on the psychogenesis and nature of these conditions, his view of the treatment of them remains entirely superficial.

### GRAPHIC METHODS IN HEART DISEASE. (a)

THE value of graphic methods in the investigation of heart affections, especially if other physical observations are made at the same time, cannot be overestimated. Hitherto, the sphygmograph has alone received the careful attention of writers on heart disease, or, at all events, other graphic methods have been only incidentally referred to. There is, therefore, abundant scope for anyone who, like the author, cares to write a book covering the entire ground of such methods of investigation. After certain preliminary remarks, the author supplies his readers with a very good account of the various instruments required, and their methods of application. He then goes on to consider normal records as obtained by the use of the instruments described. Sphygmograms, cardiograms, and venous pulse tracings are admirably discussed and very fully illustrated. Then comes a chapter on the auricular type of venous pulse and its clinical importance. The extra-systole, which is the

(c) "Symptoms and their Interpretation." By James Mackenzie, M.D., F.R.C.P., Physician to the West End Hospital for Nervous Diseases, London, etc. London: Shaw and Son. 1908.

(a) "Neurasthenie et Névroses, leur guérison définitive en cure libre." Par Paul-Emile Levy. Pp. 407. Paris: Alcan. Prix 4 francs.

(b) "Graphic Methods in Heart Disease." By John Hay, M.D., M.R.C.P., Assistant Physician, Liverpool Royal Infirmary. With an introduction by James Mackenzie, M.D., M.R.C.P. London: Henry Frowde, Hodder and Stoughton. 1909.

most common cause of cardiac arrhythmia, has a chapter devoted to its consideration. The ventricular or nodal form of venous pulse is next described in an exceptionally full and clear way. The rest of the volume is devoted to the disturbances of function to which the heart is liable, and to certain difficulties in the interpretation of sphygmograms.

This is a model of what such a book should be—not too technical, but yet scientific; free from padding, and yet sufficient for the needs of the practitioner who wishes to study the subject for himself. The series of tracings figured by the author is very representative and wonderfully complete, and for these alone the book is worth possessing, apart altogether from the text. They have been well reproduced, and will be found most reliable and useful for purposes of reference. We congratulate Dr. Hay on the publication of such an excellent manual, which we trust will do much to stimulate further research along the lines indicated so clearly by the author.

#### THE SANITARY OFFICER'S HANDBOOK OF PRACTICAL HYGIENE. (a)

THE military branches of the profession are, according to the Preface of this book, not nearly so well off as the civilian with regard to the instructions for carrying out the necessary practical work. The authors appeal to those who have had previous training, but whose memories require refreshing with regard to details. The practical work entailed in the Chemical and Bacteriological Examination of water, sewage, ventilation, foods and beverages are given. The processes have been carefully selected and the methods for working out results carefully explained. The pages are interleaved and the print is excellent. We notice one or two trivial mistakes: On page 51 there is a misprint of "4" for "24" and the omission to specify the presence of an oxidising agent in the sulphuric acid used in testing for formaldehyde might lead to the use of the pure acid and consequent failure to find the preservative. The section on "Preserved Foods" calls for especial commendation, as also, considering its size, does the chapter on Bacteriology. The authors do not claim too much for their work, and their wishes with regard to its acceptability are certain of fulfilment.

## MEDICAL NEWS IN BRIEF.

#### The Sixteenth International Congress of Medicine.

A MEETING of the National Committee for Great Britain and Ireland was held at the Medical Society of London on July 22nd, 1909, Dr. F. W. Pavy, F.R.S., President, in the chair.

It was proposed by Sir William Sinclair, seconded by Mr. Eliot Creasy, that the members of the National Committee be circularised as to the advisability of asking H.M.'s Government to invite the 17th International Congress of Medicine to meet in this country. A report was made upon the appointment of official delegates at the Budapest Congress. It was also pointed out that members of the Congress who desire to travel with the Royal Society of Medicine party should communicate at once with Mr. J. V. W. MacAlister, at 20, Hanover Square, London, W. The meeting closed with a vote of thanks to the Medical Society of London for the use of their rooms.

#### Death Under an Anæsthetic.

AT the Royal Infirmary, Sheffield, on July 21st, an inquest was held on the body of a girl of 7 years, who had succumbed to the effects of an anæsthetic. The girl suffered from earache, and it was thought a slight operation would afford relief. The child never thoroughly recovered consciousness. Artificial respiration was resorted to for over half-an-hour, and strychnine injections were tried, but without avail. It

(a) "The Sanitary Officer's Handbook of Practical Hygiene." By C. F. Wanhill, Major, R.A., M.C., M.R.C.S.Eng., L.R.C.P. Lond., D.P.H., Assistant Professor of Hygiene, Royal Army Medical College; and W. W. O. Beveridge, D.S.O., Major, R.A.M.C., M.B., C.M. Edin., D.P.H. Cantab., Analyst to the Army Medical Advisory Board. Pp. 151 and viii. London: Edward Arnold. 1909.

was stated that there were 17 other operations of the same character the same day, and 400 last year without misadventure. There had not been a death in the Infirmary under such circumstances for over four years.

The jury found that the deceased died from the effect of an anæsthetic.

#### Society for the Relief of Widows and Orphans of Medical Men.

AT a Quarterly Court of the Directors of this Society, held last week, Dr. Blandford, President, in the chair, the death of a member of the Society was reported, and seven new members elected. The sum of £1,255 was voted for paying the half-yearly grants to the forty-eight widows and thirteen orphans on the books of the Society.

The widow of one of the members applied for relief; her husband, owing to ill-health, had been unable to make any provision for his widow. A grant at the rate of £50 per annum was voted.

The Society only grants relief to the widows and orphans of deceased members. Membership is open to any registered medical practitioner who at the time of his election is resident within a twenty-mile radius of Charing Cross. The subscription is two guineas a year, or a member may become a life member by paying a sum fixed by the by-laws of the Society.

The invested funds now amount to over £100,000.

Application forms for membership and full particulars may be obtained by applying to the Secretary at the offices of the Society, 11, Chandos Street, Cavendish Square, London.

The next election takes place on October 13th. Application forms must reach the Secretary on or before September 22nd.

#### Short Hair for Girls.

A GOOD deal of excitement is said to be existing in Willesden over a circular issued to parents by the Medical Officer to the Willesden Education Committee, in which he urges them to send their girls back to school after the summer vacation with their hair cut short. He says:—

"Many parents desirous of keeping their children's heads clean find it almost impossible to do so in the case of girls on account of the fact that they wear long hair.

"There is absolutely no need for girls to wear their hair long, and if the cleanly parents will set the example of having their girls' hair cut short whilst at school, much more hygienic conditions will be established in our public schools. On the eve of the holidays I venture to make this appeal to parents to send all children to school with short hair.

"There should be no objection to doing this, and there can be no doubt that long hair in schoolgirls will come to be recognised as a badge of uncleanness. The sensible people who recognise the claims of hygiene must first set the example to those parents who are insensible of the shame which should be felt at the evidence of parental neglect presented in the dirty state of a child's head."

There is a revolt amongst the mothers, who have determined not to comply with the circular. One indignant parent, on receipt of the letter, at once waited upon the head teacher with a Bible, and pointed out that the advice of the medical officer was against Biblical teaching.

#### Hospitals' Tuberculosis Committee.

A SPECIAL meeting of the Committee was held at 76, Grafton Street, on Friday afternoon. Present:—Her Excellency the Countess of Aberdeen, Sir John Moore (in the chair), Dr. M. F. Cox, Dr. Alfred R. Parsons, and Sir William J. Thompson (Hon. Secretary).

The minutes of the previous meeting were read, confirmed and signed. Her Excellency stated that on her recent trip to Canada and the United States she had had the opportunity of meeting a number of workers in the anti-tuberculosis campaign which is being carried on so actively in America. Her Excellency was invited to address several meetings in New York, Boston, and Detroit, with the special object of describing how the crusade is being conducted in Ireland under the

auspices of the Women's National Health Association. Great interest was manifested in the movement, and the result has been the formation of committees in the cities above-mentioned for the purpose of arousing sympathy amongst American citizens of Irish parentage, and of obtaining their practical co-operation in assisting the work in Ireland.

One gentleman, Mr. Robert Collier, has already promised Lady Aberdeen £1,000 per annum for five years, with the object of equipping and starting a tuberculosis dispensary in the city of Dublin in memory of his late father, Mr. P. J. Collier, and to be called after him.

The Committee expressed their pleasure at this announcement, and their gratification at the practical results of the meetings addressed by Lady Aberdeen on behalf of the Health Movement in this country. It was agreed by the Committee that the Dublin hospitals be communicated with, with the object of obtaining their co-operation in the work of the proposed tuberculosis dispensary.

#### Bombay Medical Congress Exhibition, 1909.

It is officially notified that the exhibit of Messrs. Burroughs, Wellcome and Co., at the Bombay Medical Congress, held in February last, has received the highest award.

### PASS LISTS

#### University of Durham.

THE following candidates have passed the First Examination for the Degree of Bachelor of Medicine:—1.—Elementary Anatomy and Biology, Chemistry and Physics.—Eric Johnson, L. Everitt Markham, Roger P. Ninnis, John L. Pringle, Frank B. Robson, James S. Soutter, Gordon S. Woodman.

2.—Chemistry and Physics.—George A. Berkeley-Cole, Garfield Carse, Idris D. Evans, Robert L. Kitching, Reginald A. Hooper, Nora Murphy, Frederick J. Natrass, Carinna A. O'Neill, Grace W. Pailthorpe, Evelyn Ritson, Arthur Sutcliffe, Cedric O. Shackleton, Cyril Duncan.

3.—Elementary Anatomy and Biology.—Walter Lessey, Ivan M. Pirrie, Felix S. Rood, M.R.C.S., L.R.C.P.

4.—Elementary Anatomy.—George E. Stephenson. The following have passed the Second Examination for the Degree of Bachelor of Medicine:—

Anatomy, Physiology, and Materia Medica.—Ronald G. Badenoch, Edgar Babst, Joseph J. Brown, Theonie R. Burrell, Joseph W. Craven, Evelyn A. Constable, Sarah L. Green, Norman Hodgson, James Kerr, Francis J. Lidderdale, John G. Ogle, Charles O'Hagan, Lionel G. Pearson, Fred Phillips, B.A., Thomas C. Storey, Eleanor Walkinshaw, Samuel K. Young.

The following have passed the Third Examination for the Degree of Bachelor of Medicine:—

Pathology, Medical Jurisprudence, Public Health, and Elementary Bacteriology.—John Hamilton Barclay (Honours—First Class); Michael Brennan (Honours—Second Class).

Pass List.—Oscar F. D. Airth, John B. Alderson, William H. I. Bathurst, Thomas A. Hindmarsh, William Hudson, Harold L. James, Frank H. Kennedy, John Lumb, John H. Owen, Thomas A. Peel, Eliot Jessie Ramsbotham, Madeline R. Shearburn, Carl J. V. Swahnberg, Charles S. Thompson, Olivia N. Walker, Arthur H. Wear.

#### University of Liverpool.

At the Graduation Ceremony, on July 10th, the following degrees were conferred:—

Ch.M. (*ex-officio*).—W. Thelwall Thomas and Robert Jones.

M.D. Degree.—J. A. Murray Bligh, H. E. Heapy, H. R. Hurter, L. Hutchinson, A. Hendry, T. W. Jones, J. McClellan, J. E. W. MacFall, J. Graham Martin.

M.B., Ch.B.—W. A. Daley (first class honours), K. J. C. Bradshaw (second class honours), A. G. W. Owen (second class honours), N. W. Steinberg (second class honours), J. W. Cropper.

First M.B., Ch.B. Examination.—Parts I. and II.—C. W. Dixon, J. R. Jones, E. B. Marsh, A. C. Mooney, H. S. Pemberton, R. E. Roberts, J. St. G. Wilson.

Part II.—F. A. Belam, A. D. Bigland, H. E. Marsden, R. Martlew, Beatrix M. Walker.

Second M.B., Ch.B. Examination.—Part "A."—D. H. Clarke, R. C. Crooke, J. E. Getting, R. Heald, N. P. Laing, J. Loudon, G. W. Mooney.

Part "B."—R. W. Gemmell and M. T. Morgan.

Final M.B., Ch.B. Examination.—Part I.—J. Bamforth, J. E. Barnes, J. Campbell, A. A. Dear, E. S. Miller, W. R. Wade, T. W. Wadsworth.

Part II.—K. J. C. Bradshaw, J. W. Cropper, W. A. Daley, A. G. W. Owen, N. W. Steinberg.

Final B.D.S. Examination.—F. Halsall.

First L.D.S. Examination.—P. G. Capon, C. Q. Dinn, S. S. Tiffin, W. Williams.

Second L.D.S. Examination.—J. Burns, W. B. G. Jones, J. Tyson.

Final L.D.S. Examination.—G. P. P. Clapham.

#### University of Aberdeen.

At the Graduation Ceremony on July 21st, 1909, the following degrees were conferred:—

Degree of Doctor of Medicine (M.D.).—Williamina Abel, M.B., Ch.B.; Thomas Craig Boyd, M.A., M.B., Ch.B.; Eneas K. Mackenzie, M.B., Ch.B.; Charles J. R. Milne, M.B., C.M., Major, Indian Medical Service.

Degree of Bachelor of Medicine (M.B.) and Bachelor of Surgery (Ch.B.).—George Spencer Melvin (with Second-class Honours), William R. Allan, William J. Calder, M.A., Robert W. Chalmers, William Chapman, Douglas Craig, Robert G. Davidson, Henry Duguid, Robert W. Eddie, Alexander M. Geddes, William I. Gerrard, Elizabeth McHardy, George Macpherson, James Rae, M.A., George E. Shand, William L. Stephen, Francis W. Stuart, John E. Thompson, Robert Tindall.

The John Murray Medal and Scholarship (awarded to the most distinguished Graduate (M.B.) of 1909) was gained by George Spencer Melvin, Montrose.

Diploma in Public Health.—James Laing, M.A., M.B., Ch.B. Aberd.; James A. Milne, M.B., Ch.B. Aberd.; John A. Watt, M.B., Ch.B. Aberd.

#### Royal Colleges and Faculty of Physicians and Surgeons, Edinburgh.

THE July examinations of the Royal College of Physicians of Edinburgh, Royal College of Surgeons of Edinburgh, and Faculty of Physicians and Surgeons of Glasgow, held in Glasgow, have concluded with the following results:—Passed the first professional examination:—Roland J. Croxford, George A. Grandsoult, Joseph V. Duffy, William C. Holburn, William Bannatyne, Alexander Watson, Robert C. Craig, James Williamson.

The following passed the third professional examination:—Haripado Chatterjee, India; William Wood, Morris W. Rees, Leon Galdemar, India; John B. Michie, James M'Cusker, John M. Chrystie, Robert H. Jones, Maurice J. Anderson, William E. Hopkins, Robert Anderson.

The following passed the final examination and were admitted L.R.C.P.E., L.R.C.S.E., L.F.P.S.G.:—Thomas S. Douglas, William E. Hopkins, William J. Taugher, Canada; Angus C. Livingston, James Young, Ernest W. Wilbourne, Patrick J. Taaffe, William Browne, Seringapatam N. S. Aiyengar, Mysore; George M. MacLeod, Erachshaw Dinshaw Shroff, Bombay; Shivanarain Rozdon, Simla.

#### Society of Apothecaries of London.

THE following candidates, having passed the necessary examinations, have been granted the L.S.A. Diploma of the Society, entitling them to practise Medicine, Surgery, and Midwifery:—H. A. Hancock, W. J. Morton, and H. M. Pollard.

#### Conjoint Examinations in Ireland.

THE following candidates have passed the Third Professional Examination of the Royal College of Physicians and the Royal College of Surgeons, July, 1909:—J. T. Duncan (with Honours), A. E. Bedell, C. J. Bourke, C. P. Corbett, J. Devine, I. A. Dowling, H. C. Gilmore, R. H. Hodges, C. J. Kelly, A. M. Lanphier, H. R. L'Estrange, H. M. E. H. McAdoo, P. McGrath, Miss A. H. Mullen, J. O'Kelly, W. A. Swan.

## SUMMARY OF RECENT MEDICAL LITERATURE, ENGLISH AND FOREIGN.

*Specially compiled for THE MEDICAL PRESS AND CIRCULAR.*

**The Operative Treatment of Rupture of the Uterus, with an Account of Three Cases Treated by Abdominal Hysterectomy.**—Eden (*Journ. Obst. and Gyn. Brit. Emp.*, XV., 6).—The risks in rupture of the uterus are shock, hæmorrhage, and sepsis. The amount of shock produced by an extensive laceration, whether complete or incomplete, is always severe, and when associated with free bleeding it becomes profound. The arterial spasm and depression of circulation produced by shock are probably of service in temporarily arresting bleeding. An improvement in the general condition due to subsidence of shock may then give place to relapse from recurrent bleeding, and this improvement, followed by deterioration, is an important indication of the recurrence of internal bleeding. Hæmorrhage and sepsis are much more formidable risks than shock. The frequency with which serious bleeding occurs in rupture of the uterus, the writer thinks, has been a good deal under-estimated, and concludes that dangerous bleeding occurs in 40 per cent. of cases. The risk of hæmorrhage, though greater in complete than in incomplete rupture, is common to both. Serious external bleeding seldom occurs in complete rupture, but is not uncommon in the incomplete variety, but the real risk in both is internal bleeding. The bleeding which follows the rupture usually stops spontaneously, but if the patient survives there is risk of recurrence when the shock passes off and the circulation regains its force. This point is illustrated in Ivanoff's figures. The great majority of deaths from hæmorrhage occurred not immediately, but within from two to twelve hours after rupture—*i.e.*, after repeated hæmorrhage or continuous oozing had occurred. This establishes two points: (1) that the necessity to control hæmorrhage from the laceration must be encountered in a large proportion of cases, and (2) that the severe shock renders the diagnosis of hæmorrhage obscure, and increases the gravity of operative interference. With regard to sepsis, little need be said. Most of the cases met in hospital practice have already been infected owing to prolonged labour and repeated attempts at delivery. But if not infected at the time, the presence of a laceration opening up direct communication between the vagina and the peritoneal cavity or cellular tissue is of the gravest possible danger. Probably 50 per cent. of the total mortality is due to sepsis. Expectant or non-operative treatment has been shown to be attended by a high mortality when applied to cases of all degrees of severity. Different estimates vary from 92 to 60 per cent. The truth appears to be that it is quite unsuitable for severe cases, while successful in cases of slight or moderate severity. When only the lower part of the broad ligament is opened by a laceration of the vaginal vault, cervix, or lower segment, conservative treatment is sufficient, and, unless there is progressive bleeding, drainage only instead of tight packing. For all practical purposes an extensive sub-peritoneal laceration, opening the broad ligament and large enough to admit the whole hand, is quite as formidable as a laceration opening the peritoneal cavity, for autopsy has shown that death from peritonitis, after incomplete rupture, is by no means uncommon. Also it is difficult to tell whether a large rent has opened the peritoneum or not. These reasons justify the grouping of all large lacerations together, whether complete or incomplete. In these cases the expectant treatment, by plugging *per vaginam*, is absolutely unreliable, and tight packing, if employed, will retard the free drainage which is absolutely necessary as a precaution against sepsis, while loose packing will not control bleeding. In the majority of cases of severe rupture the writer believes that laparotomy offers the best chance. Steady deterioration of the pulse and general condition, or relapse after a tem-

porary improvement, are the only signs of continued hæmorrhage likely to be found. Opening the abdomen and securing bleeding points of itself will involve little shock, and having got thus far, the operator has three courses open to him: (1) simply to pack the rent from above and drain both up and down; (2) to remove the uterus and drain down; (3) to suture the rent and drain the pelvis. The first is probably best if the patient is *in extremis*, and every moment of importance, and if the patient rallies further operative treatment could be done 24 to 48 hours later. Hysterectomy has the advantage of fully controlling hæmorrhage and of removing a frequent source of infection, and removes the risk of repetition in a future pregnancy. Kolominkin, in 1903, obtained 140 cases of uterine rupture occurring in series in lying-in hospitals. Of these, 97 were treated conservatively, with 61 per cent. mortality; in 33 hysterectomy was done, with 36.3 per cent. mortality. As regards method, the main point being simplicity, the sub-total hysterectomy is probably best and quickest, and the important point of free drainage is easily obtained through the tear. Suturing of the rent may be regarded with favour from a conservative point of view, but it has the disadvantages of often failing to control bleeding and of leaving a possibly infected uterus; also from the position of the rent the operation may be difficult and tedious. If the uterus is sutured, free drainage must be obtained through a separate incision or through the abdominal wound. F.

**A Series of Ten Cases of Complete Rupture of the Uterus.**—Smith (*Journ. of Obst. and Gyn. Brit. Emp.*, XV., 6).—The writer reports ten cases of rupture of the uterus, treated by conservative methods, with a mortality of 90 per cent. When a series of cases such as this is examined, one asks whether other methods of treatment might not have given better results. In considering the question of treatment, those cases must be eliminated in which death occurred so rapidly that no time was allowed for anything to be done. Of the seven cases which remain, in one the patient's general condition alone was treated; practically nothing was done locally, yet the woman recovered, and has had a full term child since. The woman's condition for several hours was so serious that probably any operative measures would have had a fatal result. In one case where the child had escaped into the abdominal cavity, the abdomen was opened, the rent sutured, and a drain passed into the vagina, but the patient died in 2½ hours after a slight improvement. The cellular tissue was found to be greatly lacerated in all directions, and containing a large hæmatoma. The writer considers that any more severe operation would have hastened the end. Another case, in which the operator had a good view of the edges of the rent, and was certain all hæmorrhage had ceased, was lightly packed with gauze, the woman being too collapsed to have borne any other treatment. She rallied slightly, but died in seven hours. About a pint of free blood-stained fluid was found in the abdomen, and some coils of intestine showed early signs of peritonitis. Labour had been protracted for five days, with frequent attempts at delivery. One case had cancer of the cervix. The author considers that none of these cases would have borne any operative treatment whatever. F.

LIEUT.-COL. G. D. HUNTER, D.S.O., R.A.M.C., has been selected for the appointment of Commandant of the School of Instruction, Aldershot, in succession to Lieut.-Col. C. E. Nichol, D.S.O., and he should take up his duties on November 1st.

## NOTICES TO CORRESPONDENTS, &c.

**CORRESPONDENTS** requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

### SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs 15.12. Messrs. Dawson and Sons are our special agents for Canada.

### ADVERTISEMENTS.

For ONE INSERTION:—Whole Page, £5; Half Page, £3 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d. The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 52 insertions at £3, and pro rata for smaller spaces. Small announcements of Practices, Assistances, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

ORIGINAL ARTICLES OR LETTERS intended for publication should be written on one side of the paper only and must be authenticated with the name and address of the writer, not necessarily for publication but as evidence of identity.

CONTRIBUTORS are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland to the Dublin office, in order to save time in reforwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

DR. H. S. T.—The statement, of which you have reason to doubt the correctness, you may take as the irresponsible affirmation of an over-zealous reformer. The death rate from alcoholism has been steadily declining for years, and last week may be cited as evidence of the fact, only three deaths having been certified as from alcoholism, in a population of nearly seven millions in London and its outer ring.

### REMINISCENCES.

THE following interesting note was sent us by a correspondent: Dr. Dabbs in his magazine, *My Journal*, for July and August, publishes, among other interesting notes and gossip, some reminiscences of hospital life during his student days in the sixties and seventies, when King's College Hospital could boast of such giants on its staff as Fergusson, Henry Smith, John Wood, George Johnson, Alfred Garrod, and Partridge. His references are at times humorous as well as instructive, and as the writer of this paragraph also was personally acquainted with five of the six names mentioned, he might, but for the exigencies of space, add a few lines thereto. The following incident is vividly in his memory. The writer was one day chatting with Sir William Fergusson in his study, and on expressing surprise that the former editor of a medical contemporary, who had hurriedly quitted his post for the United States some time previously, was to be reinstated, Sir William exclaimed in his broad Scotch accent: "Eh, mon, it is sometimes necessary to hold the candle to the devil."

MR. H. M.—We do not give advice by post, nor recommend any particular physician in our columns.

UNDER-SIZED (South India).—The "system" you inquire about is run by a blatant self-advertiser, and we have no possible confidence in it. Your patient had better save his money for better purposes.

### A HOMOEOPATHIC REMEDY.

According to the latest medical theory port, taken in strict moderation, may be of distinct benefit in cases of gout.

Hair of the dog that bit my grandsires shrewdly,  
And is it true, indeed, as doctors say  
When the sharp twinge of gout assaults me rudely,  
That thou mayest help to chase the fiend away?  
I thought that "purple stream" was dammed for ever  
At which my sporting forbears strove to slake  
Perennial thirsts, but now our wise and clever  
Physicians own that this was their mistake.  
Not that I minimise my grandsires' failing.  
I own that even now I feel put out  
At thought of these upon their heirs entailing  
No worldly goods at all but only gout.  
They spent the property they should have left me  
In drinking many times their proper share;  
Of cash and constitution they bereft me,  
And precious little they appeared to care!  
They passed the flowing bowl with song and laughter;  
Their selfishness was utter and profound.  
It was not love for those who should come after,  
But simply wine that made their world go round.  
And even now I think I see them shaking  
With horrid mirth when ghostly eyes reveal  
The spectacle of their descendant taking  
"Two table-spoonfuls with the evening meal."

TOUCHSTONE.—*Daily Mail*.

## Appointments.

BROWN, D. W., M.D., M.Ch.Edin., Certifying Surgeon under the Factory and Workshop Act for the Preston (West) District of the county of Lancaster.

BROWNE, F. J., M.B., B.Ch.Aberd., Certifying Surgeon under the Factory and Workshop Act for the Aberlilly District of the county of Monmouth.

DINGLE, H., L.R.C.P.Lond., M.R.C.S., Certifying Surgeon under the Factory and Workshop Act for the Barmouth District of the county of Merioneth.

JAMES, R. R., F.R.C.S., Assistant Ophthalmic Surgeon to St. George's Hospital.

MAYNE, JOHN FITZGERALD, M.B., Ch.B.Edin., Senior Resident Surgeon at Oldham Infirmary.

WOON, T., M.D., C.M.Edin., Certifying Surgeon under the Factory and Workshop Act for the Leith District of the county of Edinburgh.

GRIFFITH, WILLIAM, M.B., Ch.B.Vict., M.R.C.P.Lond., Assistant Physician to St. John's Hospital for Diseases of the Skin, London.

MCBRIDE, C. A., M.D., C.M.Toronto, L.R.C.P., L.R.C.S.Edin., Casualty Officer to St John's Hospital for Diseases of the Skin, London.

WOODCOCK, LOUISA, M.D.Lond., B.S., Clinical Assistant to St. John's Hospital for Diseases of the Skin, London.

## Vacancies.

Sunderland and Durham County Eye Infirmary, Sunderland.—House Surgeon. Salary £210 per annum. Applications to J. F. Potts, Secretary, Sunderland and Durham County Eye Infirmary, Stockton Road, Sunderland.

Sheffield Union Hospital.—Resident Assistant Medical Officer. Salary £100 per annum, with apartments, rations, etc. Applications to Albert Edwd. Booker, Clerk to the Guardians, Union Offices, Sheffield.

Derby County Asylum.—Assistant Medical Officer. Salary £120 per annum, with board and washing. Applications to Dr. Macphail, Rowditch, Derby.

Camer'n Hospital, West Hartlepool.—House Surgeon. Salary £100 per annum, with board, rooms, and laundry. Applications to J. G. Taylor, Secretary.

Derbyshire County Council.—Assistant Bacteriologist. Salary £150 a year. Applications to Sidney Barwise, County Medical Officer of Health, County Offices, Derby.

St. Mary, Islington, Infirmary, Highgate Hill, N.—Assistant Medical Officer. Salary £130 per annum, with board and residence. Applications to the Medical Superintendent.

Berks County Asylum, Wallingford.—Second Assistant Medical Officer. Salary £150 per annum, with board, furnished apartments, attendance, etc. Applications to Medical Superintendent.

Manchester Hospital for Consumption and Diseases of the Throat and Chest.—Assistant Medical Officer for the new Crossley Sanatorium, Delamere Forest, Cheshire. Salary £100 per annum, with board, apartments, and laundry. Applications to O. W. Hunt, Secretary, Hardman Street, Deansgate, Manchester.

University of Birmingham.—Chair of Zoology. Salary £600 per annum. Applications to Geo. H. Morley, Secretary.

Cotswold Sanatorium, near Stroud, Gloucestershire.—Assistant. Salary £120, all found. Applications to the Medical Superintendent.

The Children's Infirmary, Carshalton, Surrey.—Assistant Medical Officer. Salary £150 per annum, with board, lodging, and washing. Applications to the Clerk to the Board, Embankment, London, E C

## Births.

DEWEY.—On July 20th, at Kingswear, Portsmouth, the wife of E. W. Dewey, M.R.O.S., L.R.C.P., of a daughter.

## Marriages.

BARRIS—MORRIS.—On July 20th, at St. Mary's Church, Sydenham, Oxon., John Davis Barris, F.R.C.S., elder son of Arthur Barris, Esq., to Agnes Margaret Morris, youngest daughter of the Rev. William Morris.

CAUSTON—COLLINS.—On July 20th, at St. John's Cathedral, Portsmouth, Edward P. G. Causton, surgeon, R.N., H.M.S. Cumberland to Mary Catherine Helen, eldest daughter of Charles H. J. Collings late Royal Navy.

COLE—TEMPLEMAN.—On July 20th, at St. John's Church, Weymouth, Percival Pasley Cole, M.B., B.Ch., F.R.C.S., Sub-Warden of Queen's College, Birmingham, to Amy Gladys, younger daughter of T. J. Templeman, Esq., J.P., of Stanton Court, Weymouth.

WHITE—TICHENER.—On July 22nd, at St. George's, Hanover Square, London, Charles Orr White, M.R.O.S., L.R.C.P., son of the late John Orr White, and Mrs. White, of Sunnyside, Norwood, to Edith, younger daughter of Mr. Edward Tichener, of Heath View, Walton, Epsom.

## Deaths.

ARMSTRONG.—On July 25, at Glinockie, Bracknell, Berks, Eliza, widow of Dr. Henry Armstrong, formerly of Peckham, and eldest daughter of the late Dr. Edward Long, of Barham, in her 83rd year.

TO LET.—13, St. Mary's Road, Peckham, for five years occupied by a Doctor. Three reception, five bed rooms, garden, stable. Rent £60. Apply Caretaker.

## NOTES AND COMMENTS.

### The Suggested M.R.C.S. Diploma of Edinburgh.

WITH regard to the diploma qualification of the R.C.S. Edinburgh which has been so much advocated by the Association of Medical Diplomates of Scotland, we publish elsewhere a letter of great importance from Mr. A. G. Bateman, the well-known Secretary of the Medical Defence Union. It appears that in the Medical Act of 1858 the membership is actually mentioned, and apparently the licentiate is not recognised at all. At any rate, the Edinburgh College will find their hands immensely strengthened by this statutory recognition, should they decide upon taking the proposed step. Another point is that an unqualified person was actually prosecuted by the Union for falsely assuming the title of "M.R.C.S. Edin." It would be interesting to learn on what grounds that enterprising person assumed that title—which he must have invented for the purpose, unless, indeed, he was misled by the Medical Act of 1858. The College of Surgeons of Edinburgh will strengthen their position amongst Englishmen, Irishmen and Welshmen by showing more interest in their diplomates after qualification. No more practical means could be adopted in order to consolidate and advance the interests of this ancient Corporation than by instituting a membership diploma, which, by its very creation, would arrest the attention of diplomates all over the world. So far the College has shown little sympathy with the suggestion, but licentiates are hardly likely to let the matter pass into oblivion.

### Food and Drug.

A FEW months ago we recorded a case in which the proprietor of an advertised proprietary preparation called "Antineurasthin" was summoned before a magistrate by the Inland Revenue Commissioners for not having Government stamps on the packets in which the stuff was sold. The defence was that the preparation is a food and not a drug, and that therefore no stamp was necessary. After a long argument, the magistrate found against the Commissioners, and against that decision they appealed. The appeal was heard in the Divisional Court last week, and the same arguments were paraded before the Lord Chief Justice, Mr. Justice Darling, and Mr. Justice A. T. Lawrence. In the course of the case the Solicitor-General for the Commissioners stated that the stuff contained water, milk, sugar, albumen, lecithin, mineral matter, and binding material, but he did not indicate the proportions used. A good deal of fun was made of the advertisements for the various diseases which "Antineurasthin" was good for, but it was finally held

unanimously by the Court that the preparation was a medicine, and therefore liable for duty. Mr. Justice Darling went so far as to say that if plain water was bottled and sold for curing complaints he thought it would be a medicine within the meaning of the statute. Now it is clearly a fraud to sell pure water and advertise it as a cure, and yet, instead of the Treasury prosecuting the vendors, we have a High Court judge averring that, in his opinion, the Government would be competent to share the swag.

### Jury's Censure.

ANOTHER instance in which a medical man appears to have been most unfairly treated by a coroner's jury occurred at Wrexham last week. Dr. Mitchell of that town was sent for one night as he was about to go out to a case, and asked to see a child who had swallowed a halfpenny. He gave the messenger a powder and some directions, saying that he would call next morning, as he could not come that night. No further message was sent to him, and, unfortunately, the child died of hæmorrhage, caused by ulceration of the œsophagus by pressure of the coin. He explained that, even if he had attended, the coin was too far down for him to have reached it, and that, presumably, the same unhappy result would have taken place. The jury found in accordance with the medical evidence, and went on to express the view that Dr. Mitchell had neglected his duty in not attending the deceased at once; in this rider the Coroner concurred, and one of the jurymen was offensive enough to say that if the patient had had a carriage and pair the doctor would have gone quickly enough. The two facts which would seem to have been overlooked are, first that the parents sent no further message regarding the child, and therefore anyone would presume that there was no urgency or distress, and the other that, had the other patient to whom Dr. Mitchell was called died through some similarly unforeseen accident, the jury would probably have found "neglect" in regard to that case. Truly the difficulties of practice are great enough without that ungenerous censure being passed on a medical man whenever an unforeseen catastrophe occurs.

### Female Medical School Inspectors.

THE question of medical women being appointed to public posts is constantly cropping up in one form or another, and a good deal of feeling is often expressed on both sides. It is clear, we fancy, that there are certain posts which women are not fitted to fill, such, for instance, as those of house-surgeons in male

surgical wards, or those on the teaching staff of institutions for instructing male students, but in open appointments, capable of being filled by members of either sex, surely the rule should be that the best qualified candidate should be chosen. Nor do we think it is essentially to the interest of the "woman movement" that less competent candidates are selected for appointments because they are women; in such cases there should be a fair field and no favour. We are led to these remarks by a debate which took place at the Sheffield School Management Sub-Committee last week, on the question of the appointment of a medical man to be assistant school medical officer. Some managers, led by a lady member of the committee, opposed the appointment on the ground that they wished that officer to be a woman, and they brought up the old and unsavoury argument, there was something unfitting or indelicate in medical men examining girls. As these children have probably never been examined by any other than a man doctor when they have been ill, this argument is not only improper but ineffective, and, in our opinion, greatly opposed to the proper interests of medical women. A member of the selection committee stated that though he set out with a strong determination to appoint a woman, the qualifications of the five female candidates were so markedly inferior to those of some of the men that he was bound to support the men. Surely the only argument that should avail in these cases ought to be, who is the most suitable person, man or woman, to fill the post?

**What is a Lunatic?** To regard a delirious patient as a lunatic is a not uncommon popular error. To label him as such and cart him off to a lunatic asylum is a different matter, which should in

no case be undertaken without express medical inquiry and sanction. Some weeks back, Dr. Wynn Westcott, the Hackney Coroner, inquired into the death of a printer, aged 39, who had been certified as a lunatic and removed to the local infirmary, where he died. It appeared that when at work deceased was taken ill with violent pains in the stomach, and had to go home, where he became delirious. His friends, thinking him insane, obtained a receiving officer's order for his removal. The medical officer of the infirmary testified that deceased became violent after admission, and that death was due to heart failure, consequent upon disease of heart and kidneys. The Coroner pointed out that deceased was not really a lunatic, and that it would be a great hardship for a patient to come out of an infirmary knowing he had been certified as a lunatic. This contention seems clear enough, and there can be little doubt that some sort of probation ward is wanted for delirious and violent patients about whose sanity there can be any question. If every delirious person were certified as a lunatic, not only our asylums, but our law courts, would have to be definitely enlarged to cope with the resulting increase of work. Fortunately, however, the ways of the Poor-law are not those of everyday practical life.

**Licking the Rim.** THE sources of contamination of milk on its journey from the udder of the cow to the stomach of the consumer are, like Sam Weller's knowledge of London, extensive and peculiar; all those interested in the sanitary regulation of the milk traffic can give examples of the sources of danger which beset the unwary

milk-consumer, and which, if they were generally known, would put him "off milk altogether." It has been reserved, however, for a correspondent of the *Liverpool Daily Post and Mercury* to unearth a danger which we confess we had not suspected. "This morning," he writes, "as I was walking down Harrington Street, I noticed a certain milkman pouring cream from a bottle into a can, and, in order to remove the surplus cream, he promptly licked round the rim of the bottle. Until this and similar acts are put a stop to, and their perpetrators severely punished, the dreaded consumption germs will continue to thrive in our midst." To our mind, the offence of spitting in an omnibus is a venial peccadillo compared with such a filthy trick as licking the rim of a cream-bottle; but it is difficult to conceive of any law or by-law which could reach those guilty of it. The only remedy we can think of is to report the offender to his master, and we can hardly believe that any dairy proprietor would not give instant notice to an employee guilty of so filthy a trick.

## LEADING ARTICLES.

### THE DECLINING BIRTH-RATE.

THE maintenance of a decrease in birth-rate in most of the civilised countries of the world is a fact that must be reckoned with by all who have to deal with the welfare of nations. The steady increment of a community is, broadly speaking, a sign of that vitality which is necessary for its survival in the struggle for international existence. Should any given country fail in the production of sufficient offspring to compensate for the loss by death, it is at once handicapped by competing nations whose births are in excess of deaths. To a certain limited extent the resulting disability may be compensated by superior race energy and physique, and by the better preservation and stamina of the infantile population, but, on the whole, the general proposition holds good, that the preservation of a moderate increase of population is essential to the stability of any given country. In France the problem has many years since passed into an acute stage. The matter has engaged the serious attention of the French Senate, and is likely to do so again at an early date. It is stated on good authority that there are no less than thirteen hundred childless married couples in France, while the birth-rate has steadily diminished year by year. The actual figures of the excess of births over deaths for the last few years have been:—

1902	...	An excess of 84,000.
1903	...	" " 73,000.
1904	...	" " 57,000.
1905	...	" " 37,000.
1906	...	" " 26,000.

The small overplus of the last year was converted to an actual deficit of 20,000 births in the year 1907. As may be supposed, this state of affairs has led to a good deal of commotion in France. M. de Foville, President of the Academy of Moral and Political Sciences, does not hesitate to assert that the nation is slowly but surely dying. Depopulation, he claims, is no exaggeration, and at

this rate France will soon be ripe for invasion. In another twenty years there will be two Germans for every Frenchman. To this he appends the important conclusion that the cause is political and economic, as well as moral. From his point of view the law is answerable for not a little of the mischief, inasmuch as it is lax with regard to certain methods; it has made divorce ridiculous, and it winks at pernicious teachings. With regard to Germany, Dr. Bertillon, who speaks with authority on the subject, points out that in 1850 France and Germany had an equal number of inhabitants, and that the German population increases yearly at the rate of 845,000, figures that differ in a very striking way with the French shrinkage to a point that has now reached an actual deficit. Many projects have naturally been advanced with a view to meeting the evil. One of the most promising is that of M. Richet, of the Academy of Medicine, who proposes that the State shall pay bonuses on every baby except the first-born. The suggested bonus for the second baby is £20, and that for the third £40. M. Richet believes that this plan, if adopted, would increase the births by 25 per cent. He estimates that the cost to the State would be about £12,000,000 yearly, a sum that he proposes to raise by imposing a 50 per cent. legacy duty on all collateral inheritances and on all estates left by parents to an only child. Another curious course is suggested by M. Paul Leroy Beaulieu, namely, that no person, male or female, should be appointed to any civil service or municipal office unless the parent of three children. At the same time, he advocates an annual reduction of the salaries of bachelor and spinster officials. The very nature of these suggestions proves the serious position into which France has drifted. A somewhat significant feature of the position is the fact that the State is asked by responsible statesmen, partially, at any rate, to provide for its children. That principle is clearly involved in the suggested subsidy for children after the first, and, less obviously, in the proposed condition of tenure of official appointments as regards offspring and marriage. It will probably occur to readers that something remotely suggesting the same principle is included in our present Government's proposal to reduce income-tax inversely to the number of the taxpayer's children. It is desirable that the question of the declining birth-rate should not be lost sight of in the United Kingdom. That there is some cause for alarm is shown by the fact that in Hampstead, one of the healthiest districts in the kingdom, with a death-rate of 8.5 per cent., there is a birth-rate of 14.9, as against 26.5 in England and Wales, and of 27 in the seventy-six great towns. There is little use in bringing our sanitary conditions to an ideal pitch if we permit the country to be slowly depopulated as in France. The question is one of national importance and deserves the careful attention of Parliament.

### MINERS' HEALTH.

AMONG the matters which have not yet attained the general attention they deserve at the hands of the profession is the question of industrial hygiene, which has been allowed to become too much concentrated in the hands of the Home Office officials and the employers immediately concerned. As a matter of fact, the arena of the workshop or mine being limited and under control, provides a *milieu* in which valuable experiments in hygiene can be carried out and checked, whereas most general outside measures, such as those for controlling infectious diseases, break down again and again through the medical officer not having full controlling powers over the large area and population he has to deal with. Unfortunately, the administration of the factory and workshop, from the sanitary point of view, is so broken up between the Home Office inspectors, the certifying surgeons, and the local authority, represented chiefly by the medical officer of health, that what should be everybody's business tends to become nobody's business. When matters of special interest occur they are passed on to the medical department of the Home Office, and usually interesting and valuable reports are produced on the subject, and pressure brought to bear on the employers to right what is shown to be at fault. In the mining department, however, there is no such medical staff at headquarters, and all the immensely difficult problems of preserving hygienic surroundings underground are left to special commissioners, or to chance experimenters. In a valuable paper read at the Leeds Health Congress, Professor Kenwood, Chadwick Professor of Hygiene in the University of London, made some useful suggestions for improving the health of miners. Professor Kenwood has recently visited large numbers of coal mines in England and Scotland, and said he had been much impressed by the inadequate provision made for dealing with the men's dejecta. Now, the most elementary principle in all sanitation is to remove and render innocuous the motions passed by a community, and yet at the present period of the world's civilisation we find these principles being overlooked in such a vital industry as that of mining. In hot and damp mines the danger is even greater than in the cool, well-ventilated ones, but outbreaks of enteric, and in some parts of ankylostomiasis show that apart from general malaise and ill-health caused by the loading of the air with impurities and stenches, specific dangers of a grave character are incurred. It was said by Professor Kenwood, and we have no doubt with truth, that the obstacle to reform lay with the workers themselves, and that to educate these men is a slow process. He suggests that simple latrines should first be erected, and that a sanitary scavenger should be appointed to supervise the working of the arrangements made, and that such official should have a certain course of training to enable him to carry out his duties intelligently. The use of disinfectants, too, is urged by Professor Kenwood, especially in connection with the stagnant pools of water which collect in the main roadways of wet mines. These pools are difficult to remove, are liable to become offensive, the water is often seriously contaminated, and getting disseminated by

traffic is a real source of danger. We hope that these simple and yet most necessary observations will not fall on deaf ears, and that the Home Office will see what arrangements can be made to meet the dangers set forth.

## CURRENT TOPICS.

### "Without Justification."

AN appeal has been made, as some of our readers are doubtless aware, to the public for £35,000, in order to remove the National Hospital for Diseases of the Heart, London, to another site. Sir Henry Burdett, in a letter to the *Times*, on July 30th (reproduced on page 123) condemns the whole scheme as being "without justification." At first sight, the existence of a special hospital for that particular class of disease seems somewhat superfluous, but further inquiry has shown that there is something of argument left to the other side. Sir Henry asks:—"In the name of reason, of economy, of medical science, and of what represents everything that is best in hospital administration, what justification is there to support this appeal for £35,000?" The point of economy may be conceded, and the first and last points are meaningless and begging the question in a way that is not uncommon with philanthropists. As to medical science, it can hardly be denied that the foundation and much of the best work of most of our specialists has been associated with small special hospitals. In the case of the heart there have been great advances of recent years, notably in the surgery of that organ, and there is much yet to be done by skilled and experienced observation and study in a similar direction. Why should the scientific work necessarily be confined to the great hospitals, as Sir Henry Burdett seems to imagine is the case? We are aware that the policy of swamping the small hospitals has been adopted by the King Edward VII. and the Metropolitan Hospital Sunday Funds, and we regard that policy as unjust, impolitic and injurious in a high degree to the interests and progress of medical science. One other point may be put to Sir Henry Burdett. The large hospitals exclude Scotch and Irish diplomats from their honorary medical staff. Is it to be inferred that holders of those qualifications are unfitted to treat heart disease, or are they to submit to the final limitation of their professional career in that direction by abstaining from the smaller hospitals, the portals of which are still, happily, open to men who have been educated in Scotland or Ireland.

### Medical Marriage Certificates

WE learn, with some incredulity, we must admit, from the Paris correspondent of the *Globe* that the State of Washington has enacted that before marriage each of the contracting parties must produce to the registration officer a medical certificate to the effect that he or she is in good health, and the gentleman in question has been sounding eminent French publicists as to their views on the subject. We can hardly imagine that in an individualistic community such as our own any such law is likely to be passed for the next fifty or a hundred years, at any rate, but we have equally little doubt

that as a measure for improving the race and preventing untold marriage misery, it would be highly efficacious. The discussion of the question, however, would do good in this country, if it only drew the attention of parents to the need of looking to the health of the parties which their children are to espouse, as a matter of at least equal importance—let us say—to that of settlements. We suppose not one father in ten thousand, before giving his daughter in marriage, wishes to be satisfied that the future husband is not suffering from chronic gleet, and yet every practitioner must know cases of early deaths and prolonged misery in innocent brides due to this cause. Hardly less grave is the question of syphilis. As regards the girl, too, few men know anything of her menstrual or sexual history, and only find out after marriage that she is practically disqualified for the duties of her state either by physical disability or by aversion. The subject is one whose serious and judicious ventilation would benefit the community greatly.

### L.C.C. Trams and Infection.

MANY papers have been written on the dangers of infection incurred by people travelling in public conveyances, and doubtless the risk is not inconsiderable. It is Utopian to suggest that railway or tram companies should exercise any control over their passengers, for unless a very clear case was made out for their refusing to carry a passenger, heavy damages would be awarded against them. On the other hand, such companies do owe the duty to the public of using every reasonable means to keep down preventable sources of infection. Much more is this the case when the tramway authority is a public body, and we would like to draw attention to the filthy condition which the London County Council tramcars are to be found in towards the evening. What measures are adopted to cleanse the floors and seats of the cars we do not know, but from the results visible to the eye, we suspect that they are *nil*. By six or seven o'clock in the evening the floors of the upper decks of the cars are a mass of dust, torn tickets, *débris* of tobacco, cigarette ends, used matches, and road filth. The whole of these delectable objects are frequently loosely cemented together with expectoration and saliva. Now, these hours are just those when the tramcars are most crowded with working people returning home, and each fresh entrant raises a cloud of bacteria-laden dust, to be wafted into the mouths and nostrils of his tightly-packed fellow passengers. Even the private companies, such as those owning the "tubes" have their carriage-floors washed out every few journeys, but the London County Council seem to consider themselves above such prosaic duties. We beg earnestly to call their attention to this improper state of things, and to remind them that not only are they a tramway authority but the chief sanitary authority for the county.

### Medical "Spies."

THE differing views taken by County Court judges as to the qualifications for impartial medical witnesses are interesting. Judge Bryn

Roberts has several times remarked that he attaches little weight to the evidence of colliery doctors, unless they have kept notes of the cases they attend, and that he likes to hear the evidence of the medical man who has actually had the patient under his care. In contrast with this, we have a recently-expressed view of Judge Dodd, who lately stated that, "although it was no business of his, he (His Honour) would like to make an observation, because it might act as a guide to doctors as to the rule hospital doctors ought to employ. It was a matter of general importance, because it was quite plain that if hospital doctors were to act as spies upon patients, and report the condition of a patient from time to time to his masters, or anybody with whom he might be in litigation, it would be a very dangerous thing for working-men to go into hospitals." Now, it is very difficult to please judges, who naturally differ as much as other men, and hold their own individual views as strongly as persons unlearned in law, but it seems to us that if our judges like to hear the evidence of the doctor attending a patient, and another casts such aspersions as that quoted in the evidence of the same kind, the only course is to select evidence that will suit the particular judge before whom a case is to be tried. To admit that principle, however, seems to us a most dangerous one. It is a natural and common action on behalf of employers to write to a hospital medical officer to ask for a report as to a patient's condition, and such reports are not usually coloured in favour of the employer. An independent expert is a useful factor in a case, no doubt, but the report of a medical man who has watched a case is most valuable, and it surely cannot be "spying" to give such a report, unless undue advantage is taken of the judiciary position held. And we imagine hospital medical officers will resent imputations on theirs as much as Judge Dodd would on his own.

#### Conscription and Physicians.

THE advocates of conscription urge as one of their arguments that compulsory military training would do much to improve the physique and development of the manhood of the nation, and we notice that, at the recent Leeds Health Congress, Dr. George Newman is reported to have argued that the race could not be regenerated by this means. Believing as we do that there is no particular need for regeneration in the race of Britons, although there may be plenty of room for further individual development, we do not advocate or deprecate conscription on the grounds of health. There are doubtless advantages and countervailing disadvantages in compulsory or voluntary schemes of enlistment in a Territorial Army. We do think, however, that the questions are best left alone by medical men—as they are highly contentious, political propositions, and there is nothing more calculated to cast discredit on the science of hygiene than for it to be allied, or thought to be coloured by any particular party complexion. The education controversy has illustrated, if further illustration were needed, how much discredit can be cast on religion, and how much religious difficulties are magnified when they become allied with parties in the State, and we conceive there is great danger to the promotion of

pure hygiene if it ever finds itself the badge of a political section. Science, like religion, flourishes best by devotion to the interests of the individual, and, happily, there is not much difference in the political parties as to the value of advice on sanitary questions. We trust the day is far distant when hygiene will cease to be a pure, though practical, science, and when men will attach experts in sanitation to their side for any but purely scientific reasons.

#### PERSONAL.

THE King has approved of the appointment of the following gentlemen to the consulting staff of the King Edward VII. Sanatorium, Midhurst: John Mitchell Bruce, Esq., M.D., F.R.C.P., Bertrand Edward Dawson, Esq., M.D., F.R.C.P.

THE King has been graciously pleased to approve the appointment of Surgeon-General W. L. Gubbins, C.B., M.V.O., Deputy Director-General, Army Medical Service, to be Director-General, in succession to Surgeon-General Sir A. Keogh, K.C.B., Honorary Physician to his Majesty, when the latter vacates the appointment.

PROFESSOR J. MICHELL CLARKE, M.D., F.R.C.P., has been appointed Pro-Vice-Chancellor of the University of Bristol.

THERE have been 59 fresh cases of cholera and 19 deaths in St. Petersburg since July 27th. The total number of cases under treatment is 733.

DR. J. RONALD CURRIE, Assistant Medical Officer of Chester, was last week appointed Medical Officer in succession to Dr. A. E. Thomas, resigned.

MR. JORDAN LLOYD, who has lectured on operative surgery for twenty years, has been appointed one of the Professors of Surgery in Birmingham University, to succeed Mr. Bennett May, who has just resigned.

DR. ARTHUR ROBINSON, Professor of Anatomy in the University of Birmingham, has been elected to the Chair of Anatomy in Edinburgh University, rendered vacant by the death of Professor D. J. Cunningham.

DR. GEORGE OGILVIE, Senior Physician to the French Hospital in London, entertained at dinner at the Reform Club the party of French physicians and surgeons now on a visit to this country with the object of studying our hospital administration and methods.

THE Baly medal, founded by Dr. F. D. Dyster in 1866, has been awarded to Emil Fischer, Ph.D., Professor of Chemistry in the University of Berlin, by the Royal College of Physicians of London; and the Moxon medal, founded in 1890, to Sir William R. Gowers, M.D., F.R.S.

DR. ELLIOT SMITH having presented to the museum of the Royal College of Surgeons of England some specimens from Egypt illustrating the earliest known examples of tuberculosis, cleft palate, etc., was accorded a special vote of thanks by the Council at its meeting on Thursday last.

DR. H. D. ROLLESTON will give an oration entitled "St. George's and the Progress of Physic," at the St. George's Hospital Club, on October 1st. In the evening the annual dinner will take place in Prince's Restaurant, Mr. Marmaduke Sheild, Consulting Surgeon to the Hospital, being in the chair.

# A CLINICAL LECTURE

## ON

### HEREDO-SYPHILIS. (a)

By D'ARCY POWER, F.R.C.S.Eng.,

Surgeon to, and Lecturer on Surgery at, St. Bartholomew's Hospital.

GENTLEMEN,—I want to lecture to you to-day on a case of congenital or heredo-syphilis. The boy who is coming in is aged 15, and he was admitted under my care into the Henry ward on May 11th, suffering from a discharge from the right ear. He was admitted in order that you might see how congenital syphilis wrecks, both physically and mentally. He should be an object-lesson, causing you to harden your hearts in future years when a man who is, in your opinion, insufficiently cured of syphilis, comes to you and asks permission to marry. Though this boy, as I have said, is fifteen years of age, he looks no more than seven or eight. There are no signs of puberty, and his emaciated and misshapen body is hardly sufficiently developed to carry his large and rather intellectual head. His mother tells us that he is the only child, and that she has never again been pregnant. Both father and mother are said to be healthy; there is no history of syphilis to be obtained. The mother, though well-grown, had knock-knee when she was young. This boy was born healthy, and was bottle-fed. He is said to have had a cold, with snuffling, soon after his birth, but it does not seem to have needed any specific treatment, and the mother only recalled it to mind when she was questioned. The milk teeth appeared naturally, but rather later than usual, and at eighteen months the child began to walk. It was noticed at this time that he was well-formed, except for a slight increase in the curvature of the spine. The chest was natural, and the legs were straight. Eighteen months later, when he was three years old, the spinal curvature had increased to such an extent that a poro-plastic jacket was put on; and at seven years old an attack of scarlet fever was followed by bending of the legs and other marked symptoms of rickets. The bending of the legs increased until the child had double knock-knee at the age of nine, with five inches separation between the two internal malleoli. Macewen's operation for osteotomy was then performed on each femur, and the *genu valgum* was rectified. There was no suspicion at this date that the child was other than rickety. He was sent to school, and soon attained a good position, showing a special aptitude for drawing, and gaining a prize for general progress. He never suffered from any inflammation of the eyes, but he had a discharge from his nose for many years.

Four years ago, that is, when he was eleven, he became deaf in both ears. There has been a discharge from the right ear for four years, but he has never had any discharge from the left ear. Seven days before his admission he was seized with a very sharp pain in his right ear, which passed off in twenty-four hours, but left him dull, restless and sleepless. The discharge from the ear increased in quantity and became more watery.

As some of his trouble seems to be due to his

deafness, I asked Mr. C. E. West, our aural surgeon, to examine his ears, and he reports that "the deafness in the left ear without discharge, and the period of incidence of the deafness, are in favour of inflammation of the labyrinth. This is probably bilateral, and there is in addition a suppurative inflammation of the middle ear."

That is the history of the case, and he would be classed as a case of syphilitic rickets. I want to point out the difference between syphilis and rickets, and to show you that one has no business to use the term "syphilitic rickets" any more than one ought to use the term "gonorrhoeal rheumatism." The more we know of the pathology of syphilis and of rickets, the more obvious it is that the process which has given rise to the changes in this boy are absolutely and wholly distinct from rickets.

First of all, you know that our diagnosis of hereditary syphilis is based upon three great points, points which are known as "Hutchinson's tripod," because Sir Jonathan Hutchinson was one of the first persons to describe them. They are: disease of the eyes, disease of the teeth, and disease of the ears. You must not expect that in any individual case you will get all these conditions. You will see that this boy has got two of them well marked. He is deaf, with that peculiar kind of deafness which comes on at the time when puberty usually manifests itself—i.e., between the tenth and twelfth year. As a rule, the change comes on very rapidly. This boy heard quite well at one date, and three months later he was as deaf as he is now. This deafness in heredo-syphilis may or may not be associated with middle-ear disease, but it is incurable. It is true labyrinthine deafness, and that condition the boy has at the present time. He has not the typical Hutchinsonian teeth, for Hutchinsonian teeth are smaller than usual, irregularly developed and ill-developed. The central incisors of the permanent set are notched. This boy has the notching, but not the irregularity. His teeth are well developed, but he has a giant central incisor which dwarfs the rest. There is not yet any interstitial keratitis, but it may still appear, because it usually occurs about the same time as the onset of the deafness. His bone changes are very marked. You can see, even from a distance, what marvellous alterations have taken place in his sternum. Instead of being flat, it has become raised into this great bridge, which you can use as a handle to lift his body off the couch. The long bones are markedly altered in shape, and the changes are most marked at the epiphyses, which are enlarged, as they would be in a rickety child. The upper epiphyses about the elbow are also enlarged, a very rare occurrence in rickets, if it occurs at all. The long bones are deformed at both ends in syphilis, but only at one end in rickets. It was thought, before looking at the other bones, that he had ordinary *genu valgum*; and one felt the more sure of that because his mother said that when she was young she had herself bad knock-knee. But even then one ought not to have over-

(a) Delivered at St. Bartholomew's Hospital on Wednesday, June 23rd, 1909.

looked the fact that the ankles are as badly affected as the knees, and that both upper and lower extremities are involved. When you examine the metacarpal and metatarsal bones, you find he has some thickening of the epiphyseal ends, where marked changes are still taking place. You never see that in rickets. His colour is characteristic; he is very pallid. Syphilis manifests itself by an extreme hæmolytic; the red cells are broken up and destroyed at a very early period of the syphilitic changes, and he has thus got the waxy pallor of a syphilitic subject. In some cases of syphilis the hæmolytic is marked by hæmoglobinuria, but so far as we know he has not suffered in this manner. He has not the ordinary rickety back either. It bends somewhat, but when you turn him over the prominence does not disappear. That would remind you of Pott's disease, which is tuberculous. But this prominence of the spine and the falling together of vertebræ in front also occurs in heredo-syphilis.

His mental condition is a very remarkable one; he is now almost imbecile. Though he can make himself understood, he seems to have largely lost the power of speech. Yet he has really been a very talented boy; this book shows that he has been able to draw very nicely, while his writing, as you see, was very much better than my own, and is far above the average. And that is another point in favour of syphilis as the cause of his troubles. It has been very difficult until lately to determine how far the mental deterioration in these cases has been due to the deafness, and how far to the changes which are taking place in his nervous system. Much work has been done lately to enable us to distinguish between the two. A boy who suddenly becomes deaf is largely cut off from all his surroundings; but even then a boy ought not to lose his intellectual capacity, as this boy has done. We are now able to distinguish syphilitic deterioration from that due to deafness by Wassermann's test. If you examine the cerebro-spinal fluid and find evidence of leucocytosis in that fluid, you are fairly sure that you are dealing with mental deterioration due to cerebral changes, and not merely to deafness. In a few years this boy's condition will have passed from bad to worse, and he will either become a general paralytic, or will have some tabetic condition. Our observations are not yet complete, but if the cerebro-spinal fluid does not give the Wassermann reaction we may be able to educate him, and perhaps obtain satisfactory results. I am afraid, however, that this is the beginning of juvenile general paralysis. And "juvenile" leads me to remark once more that you would take this patient for a boy of eight or ten, whereas he is fifteen. His nose is suspicious of syphilis, and I think you may regard him as a well-marked but rare case of heredo-syphilis. You never saw a rickety boy with such a well-shaped chin, nor such a good head; and although rickety children have protuberant foreheads, they have small faces and weak jaws.

The reason for laying stress on the differences between rickets and syphilis is on account of the difference of treatment which is required. You would be very apt—unless you were warned—to regard a case like this simply as one of rickets and to treat it by ordering the administration of fats, and by telling the mother to send the child as much as possible into the fresh air. Unless you recognise the syphilitic element, no thought would be given to the infection by spirochætes which are working such havoc with the tissues, first with the bones, and now, unfortunately, with the nervous system. Care and attention to the points about

which I have told you will enable the diagnosis of syphilis to be established, and as soon as this is done mercury is given, the spirochætes are killed, and the formation of fibrous tissue, which is the destructive agency in the bones and nervous system is thereby prevented. But when once the fibrous tissue is formed, nothing will avail to cure, and the patient becomes a useless member of society.

Learn, then, from this boy that a patient may show very little evidence of syphilis until he arrives at the age of puberty. This delayed appearance of syphilis in its worst forms is well recognised by those who see many cases of syphilis, and it is known to them as *syphilis hereditaria tarda*. Such a patient, like this boy, is born apparently in good health sometimes of parents who would not be suspected of syphilis, and from whom no history of the disease could be obtained, even if it were desirable to ask for one. The child is bright and healthy for the first few years, and then there comes a change which is attributed to some trivial cause—a fall, a cold, influenza, scarlet fever, even the onset of puberty itself. Any condition, in fact, which leads to some impairment of vitality, whether it be physiological or pathological, is sufficient to call into action the latent virus of syphilis. Why or how syphilis lies dormant are matters which pathologists are only now beginning to explain. They tell us that during the long latent periods of syphilis the spirochæte is probably in some intracellular resting stage, when it is harmless, but ready to start into activity and to multiply rapidly after slight changes in the cells which harbour them.

Treatment, if it is to be effective in curing the patient, must be continuous. A few years ago, if this boy had come to the hospital, we should have given him grey powder two or three times a day, and as soon as his snuffles had ceased or his back had become a little less painful we should have said that he was cured. His symptoms, in other words, would have been treated, and not his disease. To cure the disease it is necessary to persist with mercurial treatment not only for months, but for years. The treatment may be interrupted occasionally, but the object of modern treatment is to have small quantities of mercury circulating in the blood for long periods of time, rather than to give large doses for a short time. The best way to give mercury is by means of intra-muscular injection, and it is always best to begin with calomel. This boy has had half a grain of calomel once a week whilst he has been in hospital. It has been injected deeply into his gluteal muscles in the form of a cream, made up with creosote and camphoric acid so that the injections may be painless. I think that he is a little better for them, but his condition was nearly hopeless when he first came under our notice. When the mercury cannot be given by intra-muscular injection, as, for instance, when the mother objects to the pin-prick which is necessary, it is better to order the mercury by inunction if you are treating children in private, because it will be persisted in for a longer time, and will be done more thoroughly than if powders or tabloids are recommended.

The prognosis for this boy is bad. I think he will go from bad to worse, his intelligence will still further deteriorate, he will become a general paralytic, and from this condition he will be mercifully relieved by death, due, perhaps, to pneumonia or phthisis.

You have not wasted your time to-day, gentlemen, if you have learnt that some cases of "rickets" are really syphilitic, and should not be called rickets at all.

NOTE.—A *Clinical Lecture* by a well-known teacher appears in each number of this journal. The lecture for next week will be by Horace Law, M.D., F.R.C.S., Surgeon to the Throat Department of Adelaide Hospital, Dublin, and Consulting Throat and Ear Surgeon to the Stewart Institution. Subject: "Adenoids; Some Causes for their Enlargement and Reasons for their Removal."

## ORIGINAL PAPERS.

### ON IMMUNITY. (a)

BY PROFESSOR ELIE METCHNIKOFF,  
Of the Pasteur Institute, Paris.  
[SPECIALLY REPORTED FOR THIS JOURNAL.]  
(Concluded from page 89.)

As explained earlier, the bactericidal action of the complements is intimately associated with another category of substances—viz., Ehrlich's amboceptors. Incapable of destroying or damaging the infective agents, the amboceptors impregnate them and promote the bactericidal function of the complements. While, however, the latter are localised in the phagocytes, the amboceptors exist in the humours of the living organism and readily pass into the liquid that accumulates round the microbes. These are unquestionably humoral substances that play a part in the mechanism of immunity. Nevertheless, these amboceptors are, after all, only phagocytic substances excreted into the blood, and passing thence into the humours. This has been established by several observers, who have shown that the origin of the amboceptors is in the spleen, bone marrow, and lymphatic glands—i.e., in organs containing an abundance of phagocytes. It has been shown indeed by Wassermann and Citron that the amboceptors take origin on the very site of introduction of infective microbes, just where large numbers of phagocytes are found.

In the early stages of the researches bearing on the amboceptors, it was believed that they were substances which helped to destroy the microbes, though foreign to the system of phagocytic defence, but after a time it was made clear that, since they were phagocytic products, the amboceptors were only one factor in this defence.

The exact mode of action of the amboceptors on microbes is unknown, so little marked is it; in fact, the infective agents impregnated with amboceptors go on living and multiplying, as usual, and they actually retain their pathogenic properties, only they are now amenable to the action of the complements, and are more liable to be seized and enveloped by the white corpuscles.

In the case of very fragile microbes, such as the cholera vibrios and their congeners, the combined action of the amboceptor and the complement brings about the destruction of the bacteria, accompanied or not by their granular transformation. The great majority of pathogenic agents, however, are able to resist the action of a mixture of these two substances as obtained outside the body in blood serum, so that in this instance there can be no question of any bactericidal action, strictly speaking. But, impregnated as they are with amboceptor and complement, the microbes readily become the prey of the white corpuscles, the mixture of these two substances being specially to prepare the way for phagocytosis. On this account Wright has applied the term *opsonin*, and Neufeld the term *bacteriotropin* thereto.

Having made up their minds as to the trivial importance to be attached to these agents in the destruction of infective microbes, the partisans of the humoral theories now fall back on the opsonins and bacteriotropins as humoral factors which play a great part in immunity. Incapable as they are of inflicting the slightest damage on the microbes, their only effect is to facilitate their absorption by the phagocytes. Sir A. Wright, who has especially elaborated this theory, insists on the subordinate part played by the white corpuscles, which, in his opinion, merely respond obediently to the indications of the opsonins. He even

measures the progress of immunity and recovery by the opsonic power of the blood serum. But, insisting on the preparation of the morbid agents by the opsonins, Wright admits the function of the phagocytes in getting rid of the microbes; he even admits the possibility of spontaneous phagocytosis taking place without the intervention of the opsonins, the latter nevertheless playing an important part in accelerating and facilitating this function of the white corpuscles.

It is highly probable *à priori* that the phagocytosis—i.e., the digestion of the microbes by the phagocytes—is subordinated in the organism to influences that favour this process. In intestinal digestion the secretion of pancreatic juice is promoted by other elements, such as *secretine*, so that there is no fundamental objection to the theories of Wright and Neufeld. The only thing against them is the method on which they were founded. All the researches bearing on opsonins and bacteriotropins were carried out with humours and white corpuscles withdrawn from the organism and mixed with microbes *in vitro*. This method of demonstration cannot throw any light on what actually takes place in the living organism. The fate of the theory of the bactericidal properties of the humours, based on experiments *in vitro*, might well serve as an object-lesson to warn us against results obtained by such means. If it be true, as admitted by numerous investigators, that opsonins and bacteriotropins are mixtures in various proportions of complements and amboceptors, it is not difficult to conceive that the mode of action within the organism may be something quite different to that which takes place *in vitro*. We have already called attention to the fact that the complements are contained in the phagocytes from which they do not escape under normal conditions.

In researches on opsonins and bacteriotropins, researches conducted under the empire of humoral views, attention is usually directed only to the action of the blood in favouring phagocytosis. The white corpuscles are looked upon as constant elements which have only to obey the injunctions of the opsonins. But white corpuscles are living organisms which are extremely sensitive to external conditions, and vary within very wide limits. The slightest change in the saline contents of the ambient liquid is sufficient to modify phagocytosis in a very marked degree. The white corpuscles of persons suffering from different diseases display a pronounced diminution of their vital properties. According to Dr. Perou, half the cells of a person suffering from myelogenic leucæmia are deprived of the power of seizing microbes.

In view of these data, several observers have insisted on the necessity of investigating the phagocytic function of the white corpuscles, as well as the opsonic properties of the blood serum. There is all the greater reason for this, seeing that the destruction of microbes plays the principal part in the struggle of the organism against infective agents.

Now this destruction is effected by robust, living phagocytes. Although the absorption of the pathogenic bacteria by the phagocytes, an act favoured by the opsonins, is a step of great importance, it is, after all, only one step in a whole series of phenomena which culminate inside the phagocytes in the digestion of the microbes. When the latter, after absorption by the white corpuscles, do not die owing to a lack of bactericidal substances, the organism remains in a state of inadequate defence, and succumbs to the infection. Certain very resistant microbes, such as the spores of the tetanus bacillus, may remain a long time inside the white corpuscles without giving rise to this terrible malady, but directly the corpuscles are subjected to any injurious influence, such as a chill or overheating, the spores, until then imprisoned, burst their bonds, wriggle themselves free, and promptly determine fatal tetanus.

These data will explain why, as pointed out by several physicians, the opsonic power alone does not afford a trustworthy indication of the resistance of the organism.

Subjected to all sorts of influences, favourable or otherwise, the phagocytes, in their attack on the microbes, have to reckon with the resistance of the infective agents. In some instances the latter secrete

(a) Address delivered at Stockholm under the provisions of the Nobel Trust.

substances that damage the white corpuscles to such a degree as to cause them to disappear altogether. More frequently, however, they are merely damaged to the extent of becoming unable to absorb and destroy the microbes. These substances, aimed at the phagocytes, have been termed *aggressins* by Dr. Hail. They are said to be special poisons which electively attack the phagocytes. In order that our defensive cells may discharge their function adequately they must be protected against the microbial aggressins. It has even been surmised that salutary phagocytosis can only take place by the aid of some preparatory action of a kind capable of neutralising the aggressins, an action derived from the elements of the intruders. Now it appears from a large number of observations that the white corpuscles very readily absorb the aggressins without the latter undergoing any change. Wassermann and Citron's researches show that the secretions of pathogenic microbes elaborated outside the organism yield a product which, when introduced in large amounts into the organism, interferes with phagocytosis. But the very microbes that produce these aggressins are readily absorbed by the white corpuscles when in a state of unconstrained activity.

The phagocytes are capable not only of struggling against the aggressins—i.e., against the microbial poisons acting specially on the white corpuscles, but even against violent poisons capable of killing the organism. This is a point of the greatest importance in the study of immunity. After the admirable discovery by Behring of bacterial contra-poisons, the view was put forward that the defence of the immune organism lay more particularly in the neutralisation of the toxins produced by the microbes. The latter, consequent upon this neutralisation, are deprived of their principal arm in the attack on the organism, and forthwith become absolutely inoffensive beings, which readily become the prey of the phagocytes—in other words, phagocytosis, though brought to bear on living microbes, would be reduced to an act of altogether secondary importance.

Numerous carefully worked-out data are altogether in opposition to this view. It has been amply demonstrated that white corpuscles do not fear microbial poisons, readily absorb them, and render them inoffensive. This was specially well shown in investigating the poisons in the bodies of infective microbes known as *endotoxins*, and Besredke's researches on this point are quite conclusive. When he injected into the peritoneal cavity of the guinea-pig typhoid bacilli that had been killed and rendered incapable of giving rise to infection, the typhoid endotoxin proved fatal to the animal in the course of twelve hours, but when he repeated the experiment with animals whose abdominal cavities contained a large number of robust white corpuscles, these seized upon the microbial bodies and thus saved the animals from certain death.

Bail and Weyl obtained similar results by employing the poison of the staphylococcus. Injected alone, the poison killed young rabbits in a few hours; injected along with a certain quantity of white corpuscles the poison produced no effect, and the animals survived.

Similar observations might be multiplied almost indefinitely, and they pave their way to the conclusion that phagocytes not only secure immunity against infective microbes, but also against the poisons secreted by them. Of all the elements of the organism, the phagocytes are distinguished by their comparatively refractoriness to intoxication.

This is so markedly the case that white corpuscles may even resist poisoning by mineral poisons. At a time when the properties of endotoxins were imperfectly apprehended, when, too, the search for soluble bacterial poisons in the organism presented extreme difficulty, Besredke set to work to ascertain the protective part played by the corpuscles towards comparatively insoluble arsenical salts. For this purpose he took the trisulphide of arsenic, the crystals of which are readily absorbed and modified by the phagocytes. He was enabled to satisfy himself that when the peritoneal cavities of his guinea-pigs contained plenty of white corpuscles, they preserved the animals from fatal poisoning by phagocytising the crystals of trisulphide of arsenic. Since then similar observations have

been repeatedly made, and it is now generally recognised that many toxic and medicinal substances, when introduced into the organism, are taken up by the white corpuscles and can be detected within them. Still more recently Dr. Carles, of Bordeaux, demonstrated the absorption of salts of lead by the white corpuscles. These salts, absorbed in an insoluble state, become transparent inside the phagocytes, but when these are exposed to the vapour of sulphuretted hydrogen, they turn black. In seizing the poisons, the white corpuscles, as primitive elements comparatively refractory to intoxication, preserve the noble parts—the nerve, hepatic, and other cells—from injury.

The data at our disposal authorise the unhesitating conclusion that the phagocytic system constitutes the principal defence of the organism against every kind of infective agent, as well as against their toxins. The natural immunity which man possesses against many diseases depends on the ability of the phagocytes to absorb and render innocuous the infective microbes. It is unnecessary to mention that the phagocytic reaction derives every assistance it can from the organism. For instance, when infective microbes gain an entry, the white corpuscles avail themselves of vascular dilatation and nervous influence that dispatches them to the field of battle, and every possible influence is thus brought to bear.

In immunity acquired by vaccination, or after an attack of the disease, the organism presents a whole series of modifications. Stress has been laid on the enhanced properties of the humours under these conditions, and, in point of fact, the blood serum is found to contain large quantities of amboceptors and bacteriotropins (probably identical), which prepare the microbes for undergoing phagocytosis. But, as already shown, the amboceptors are phagocytic products, and for them to be poured out in large quantities into the humours, the phagocytes must have undergone modifications within the organism that has acquired immunity. This fact, which might *à priori* have been anticipated, is not easy to demonstrate in an exact manner. It occurred to Mr. Petterson, with this object in view, to introduce into the organism white corpuscles from animals vaccinated against certain diseases. He found that these elements afforded protection against quantities of infective microbes many times superior to that required to cause death. On the other hand, the white corpuscles of organisms not possessed of immunity were powerless to produce this result.

In view of the great importance of this fact, Salimbeni instituted a series of experiments at the Pasteur Institute in order to verify Petterson's results. By means of an extremely exact method, he was enabled not only to confirm, but even to extend its scope. He showed that the white corpuscles of the immunised organism are the actual source of protective substances, and that, too, at a time when the blood serum presents no change whatever. In spite of repeated washings, the phagocytes were still capable of affording immunity. In the course of these researches Salimbeni demonstrated that at a time when the humours had already completely lost their protective qualities the organism nevertheless remained refractory and resisted fatal doses of infective microbes. This fact, along with many others of the same kind, yielded a result of the greatest importance—viz., that even in acquired immunity the cellular properties preponderate over the humoral properties.

This being so, it may appear paradoxical that, in spite of the profound modifications which they have received in the organism, the white corpuscles display no increase of their phagocytic function, properly so-called. They absorb the infective agents just to the same extent as white corpuscles withdrawn from a normal organism when they are brought into contact with the humours of the immunised organism. Since the earlier researches of Denys and Leclef, various observers have insisted on the accuracy and the importance of this discovery. It must not be forgotten that these experiments were carried out with white corpuscles withdrawn from the organism and studied *in vitro*. Notwithstanding all that has been said on this point, this objection must be sustained. They are comparing the phagocytosis of the white corpuscles

of an organism subjected for weeks and months to vaccinal injections, and kept all this time in captivity with the white corpuscles of a fresh organism which has not been tampered with, so that it is obvious that the conditions are far from being identical.

But even if it had been established for certain that in acquired immunity the property of the white corpuscles to absorb microbes was in no wise modified, this result would in no way invalidate the existence of a general increase of the defensive power of the phagocytic organism. We should merely have to admit, as in acquired immunity, that there is no increase in the production of complements, so there is no enhanced power of absorption. The augmentation in the defensive power merely amounts to a super-production of preparatory substances by the phagocytes.

The totality of the phenomena observed in immunity may consequently be reduced to a series of biological acts, such as the sensitiveness of the phagocytes, their active movements towards places threatened by invading microbes, and to a series of chemical and physical acts which determine the destruction by digestion of infective agents. For a dozen years past, under the empire of Ehrlich's theories, numerous observers have applied themselves with great zeal to the elucidation of the intimate phenomena of immunity. Ehrlich himself assumed that the amboceptors, which are present in abundance in acquired immunity, combined in exact proportions with the complementary molecules, on the one hand, and with those of the microbes—*i.e.*, their receptors—on the other. Various authorities, M. Bordet at their head, challenged this theory. According to these, the amboceptors are not deserving of their name because they do not act the part of chemical go-betweens of the complements with the microbes, but act on the latter like a mordant in dyeing textures. Bordet, therefore, calls these substances "sensitisers," in virtue of their property of promoting the action of the complements on the microbes. The whole process, in his view, belongs to the category of phenomena of molecular absorption taking place in variable proportions.

During the ten years or so during which the two theories were under discussion, the delicate and complex problem of the intimate mechanism of immunity has not even now been finally settled. It is only fair to state, however, that several modern authorities maintain the view that the action of the organism on the microbes does not belong to the category of chemical phenomena, properly so-called, but is rather of the nature of the physical action of colloids, some of which emanate from the microbes, while others belong to the organism. Attempts have been made to establish an analogy between substances met with in immunity and colloids, and sundry authorities are almost on the point of admitting that the complements are lipoids similar to those entering into the composition of animal organs.

These researches justify the hope of results of the highest importance in the near future, but for the time being they are merely incursions on a domain strewn with all sorts of difficulties. The part played by the phagocytic system, on the other hand, has survived the period of probation, and is now a firmly established doctrine.

The question now arises whether the data accumulated by so many years of patient study and ardent debate are capable of application in medical practice. The general law that in all cases of immunity the phagocytic reaction is well marked, leads us to the conclusion that the degree of phagocytosis may assist in prognosis. Ever since I began the study of phagocytosis I have convinced myself that the more microbes are absorbed by the white corpuscles, the greater are the chances of recovery. A distinguished Swiss veterinary surgeon, M. Zschokke, was the first to apply this rule in combating contagious mammitis of cows. He showed that free phagocytosis of the streptococcus, the infective agent of the disease, indicates a mild course, and therefore a favourable prognosis. The fate of cows attacked by "gelber galt" depends on the intensity of the phagocytosis, and when this is feeble the cows are sure to die. Subsequently, however, it was found that in some instances the cows did not recover in spite of the fact that most of the

streptococci were inside the white corpuscles. These exceptions induced Mr. Vrijburg to undertake further investigations. Just as one might have anticipated in accordance with the phagocytic theory, the victory of the organism over the infective microbes entails not only their absorption by the white corpuscles, but also their ultimate destruction. Now cases were met with in which the streptococci of contagious mammitis, after absorption by the phagocytes, broke up the cells and got free, being thus enabled to continue their lethal work. To justify a good prognosis we must not only ascertain the degree of phagocytosis, but also establish the condition of the corpuscles and the contained microbes. This example ought to serve as a lesson to those who imagine that it is sufficient to ascertain the opsonic power to be able to forecast the course of the disease or the acquisition of immunity.

The degree of phagocytosis may also serve as a guide in other diseases due to the streptococcus. Professor Bumm, of Berlin, for instance, states that in puerperal fever marked phagocytosis is indicative of approaching recovery, whereas ill-marked phagocytosis authorises the worst fears.

In the treatment of disease by vaccino-therapy, suggested by Sir A. Wright, phagocytosis enables us to measure the opsonic powers of the blood, and this may be of service to the physician. We have already mentioned that this method is now gradually being supplemented by the determination of the property of the phagocytes independently of the opsonic action, properly so-called, and for some time past phagocytosis has been employed with success in the diagnosis of certain infectious diseases.

Among the practical applications of the phagocytic doctrine may be mentioned the application in surgery of substances capable of attracting a large number of white corpuscles to the field of operation threatened by infection. Several surgeons in France and Germany introduce into the abdominal cavity of their patients superheated blood, nucleic acid, or other substance, for the purpose of bringing an army of white corpuscles to bear on the microbes, and the results are so encouraging that we may look forward to a fresh step in dressing methods in the near future. At the beginning of the new era in surgery, one's whole attention was concentrated on the microbe, and the subjects were inundated with antiseptics, but it was soon discovered that these poisons are dangerous to organisms which require to be handled gently, so antiseptics gave place to asepsis. Now we know that phagocytosis is of valuable assistance in the defence of the organism, endeavours are being made to modify surgical methods so as to turn to account means of increasing the number of phagocytes.

Among therapeutical methods of recent introduction must be mentioned that of Professor Bier, which consists in the methodical application of dry cupping for the purpose of increasing venous stasis round abscesses, etc. How are we to explain its success? Although all contradictions have not yet been explained away, the general view is that phagocytosis is an important factor in obtaining a cure by this method.

It is not surprising, in view of all we know on the important part played by phagocytosis, that zealous search is being made for conditions capable of reinforcing phagocytic action, and numerous communications have appeared on this subject of late. Among substances that stimulate phagocytosis is quinine. Weak solutions, 2 parts in 100,000, remarkably increase phagocytic energy, whereas solutions fifty times stronger have an opposite effect. Neisser and Guerrini have investigated a whole series of substances that stimulate phagocytic activity, among them being certain solutions of peptones. This question of *stimulines*, inaugurated by us many years ago, and which appeared to be dead and buried, has recently come to the fore again.

The theory of phagocytosis, formulated upwards of a quarter of a century ago, hotly contested on all hands for many years, is now admitted by a large number of authorities in all parts of the world, and it is, so to speak, only to-day that it is beginning to find practical application. We are therefore justified in hoping that the future will reveal more than one

means of bringing phagocytosis to bear in the interest of health.

The subject I have just dealt with may serve to demonstrate the usefulness of purely theoretical research. The study of the digestive organs in lower animals, long since disappeared, has little by little enlarged the scope of investigation, and has culminated in a new conception of immunity, and in the search for methods for combating infection and ensuring the resistance and the recovery of the organism.

## THE DIETETIC DECHLORIDATION CURE IN BRIGHT'S DISEASE. (a)

By F. WIDAL, M.D.,

Of the Faculty of Medicine, Paris.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

OF mineral substances, the chlorides present most interest to the physician, for, by studying them, he is enabled to appreciate the hydropiginous action of retained chloride of sodium, and the remarkable effect of chloride restriction on the disappearance of oedema.

Since 1902, with the help of Dr. Lemierre, I succeeded in establishing on an irrefutable basis the part taken by chloride of sodium in the pathogenesis of Bright's disease. For the first time we managed to produce oedema, which may be regarded as experimental, in patients suffering from interstitial nephritis, simply by adding three or four drachms of supplementary salt to the diet. It had previously been suggested that the retention of the other saline matters might, like chloride of sodium, determine oedema, but I demonstrated by a long series of researches that of all the soluble substances, chloride of sodium is the only one which need occupy the mind of the physician in connection with renal oedema. I showed, in particular, that urea, which is so often retained in Bright's disease, accumulates more particularly in the blood, and in the course of our investigations we have never been able to convince ourselves that retained urea exerted the slightest hydropiginous action. The question may indeed be regarded as settled. As Dr. Von Koranyi remarks, "the unquestionable part played by chloride of sodium, and the negative influence of the products of nitrogenous disassimilation, are facts of capital importance, though in opposition to my earlier impressions."

Indispensable to organic life, chloride of sodium acts as a compensatory agent for molecular deficiencies, it is composed of molecules which are able to pass through the membranes of the body in any direction, and the vessel walls need not be damaged for it to escape therefrom.

Dr. Strauss found that in some subjects of Bright's disease the oedema disappeared when polyuria and polychloruria were induced, and this led him to prescribe diuretics, and to reduce the quantity of alimentary salt, he specially insisted on milk diet as a means to this end. Just at that time, Dr. Javal and I published the earliest results of our researches on the dechlorination cure, mentioning the case of a renal subject in whom, on several occasions, we had been able to determine the appearance and subsidence of oedema by varying the quantity of ingested chloride of sodium. We showed that in patients with chloride retention even milk may be too rich in chlorides, and it seemed desirable, as we pointed out, to try to substitute a more generous, more agreeable, and altogether more efficacious diet for the milk. We showed it to be possible in many instances to dis-

card milk in favour of a diet less rich in chloride, and we arrived at the rather startling conclusion that a diet largely composed of meat and other solids hitherto regarded as highly unsuitable for renal patients might prove far more beneficial than milk, provided such food be taken without salt; moreover, that the addition of half an ounce of salt sufficed to render such a diet actively injurious.

We must not forget that under certain conditions alone milk will suffice to maintain nutrition and dechlorination for a time, but to order milk with a free hand for a renal patient is to expose him to the risk of taking a diet too liquid and too rich in chlorides, one, too, which contains an abundance of albumen. The amount of milk required to provide a maintenance *regimen* contains four times more chloride than a saltless mixed diet answering the same purpose; it contains six pints of water, and not less than four ounces of albumen, that is to say, more than many renal patients can tolerate.

We established the fact that not only is a saltless diet able to check the further progress of renal oedema, but that it will even cause it to retrocede. Thereupon we proceeded to ascertain the indications for this cure, to define its application, and to establish the composition of the dietary to be compiled with this object in view.

Hydration of the tissues takes place in two stages: first there is infiltration of the deeper tissues, not appreciable to sight or touch, constituting the *præ-oedema* stage, followed sooner or later by outward and visible subcutaneous oedema. The existence of the former can only be ascertained by the aid of the scales, and in practice renal patients should always be weighed at stated intervals. The invisible oedema, revealed only by the weighing machine, involves the viscera, and may pave the way to a group of visceral disturbances, formerly known collectively as *uræmia*, but which are in reality due to chloruræmia, a term that signifies chloride retention in the organism, but not necessarily in the blood. Visceral chloruræmia may give rise to various troubles referable to the stomach, intestine, nerve centres, and even the kidneys.

Albuminuria, which in some subjects of parenchymatous nephritis increases or diminishes according to the degree of chloride retention, is, in our opinion, due to the oedema which, in this instance, is situated in the kidney.

The kidney is never absolutely impermeable to chloride. The degree of impermeability varies within wide limits; indeed, it varies in the same subject at different stages of the disease. In many cases renal permeability is still such as to allow of the moderate use of salt with food, but in other instances the kidneys offer such an obstacle to the passage of chlorides that it is necessary to push the withdrawal of salt to its ultimate limits.

The dechlorination cure comprises two indications: to rid the organism of the salt and oedema which encumber it; then to formulate a dietary, the richness of which in chlorides is in proportion with the degree of the renal impermeability to salt of the patient.

When, therefore, we are called to a patient with renal oedema, the first thing to be done is to place him on a strictly saltless diet. We must watch the case, keeping a chart of the weighings, and methodically ascertaining the chloride balance, and in this way we shall be enabled to establish the limit of toleration with approximate accuracy—a limit which we must studiously avoid reaching in the diet.

(a) Abstract of Paper read at the Twenty-Sixth German Medical Congress.

It is easy enough to ascertain the quantity of salt ingested. If the patient is on milk diet we know that milk contains 12 grains of chloride to the pint, if he be on mixed diet we may calculate that he is taking about 25 grains of natural chlorides, and this may, by appropriate selection, be reduced to 15 grains a day.

Everyone who has had any experience of the dechloridation treatment is aware of the readiness with which in some patients oedema subsides under its influence. But this is not invariably the case, and the treatment may present difficulties. Each patient has his own formula of chloridation and dechloridation, and this the physician must seek to grasp in order to obtain the best results. In some cases dehydration takes place but slowly, and it may be hastened by the administration of diuretics.

As soon as dehydration is complete, and the weight remains stationary for several days, we may cautiously proceed to try the patient's limit of permeability—*i.e.*, to what extent we may venture to enrich his food with chloride.

The dechloridation cure, after all, is only the treatment of a syndrome—*viz.*, chloride retention. It does not enable us to combat all the troubles to which nephritis exposes the patient, least of all those due to nitrogenous retention. Chloride of sodium and urea are not the only substances held back by the diseased kidney, though they are no doubt the most important, and in any case they are the ones we know most about in connection with Bright's disease.

In one category of cases the renal insufficiency bears on the products of nitrogenous disassimilation, while in another it takes the form of chloride retention; in other words, there are two types of cases, the nitrogenous, as opposed to the chloride, type of renal disease. In such subjects, suffering from this dissociated insufficiency, we are enabled to study the symptoms of each type of retention at our leisure. Usually, however, nitrogen and chloride of sodium are both held back by the kidney, especially as we approach the terminal stages of the disease, but in spite of the difficulty that is often experienced in differentiating the symptoms due to nitrogenous from those due to chloride retention, no diagnosis can be regarded as complete unless it includes the nature and extent of the nitrogenous or chloride disturbances from which the patient is suffering.

Chloride retention and nitrogenous retention differ in their clinical effects to which they respectively give rise, and this difference is dependent upon the process of accumulation peculiar to each. The function of sodium chloride being to maintain the osmotic equilibrium of the humours, it quits the blood and passes into the tissues in order that the blood may remain isotonic with the other organic fluids. Urea is a substance specially adapted for renal elimination, and when its passage through the kidney is hindered it does not, as does sodium chloride, exhibit any tendency to pass back into the tissues, but it accumulates in the blood, and it weighs particularly on the epithelium of the tubuli. The blood becomes surcharged with this substance, and thus we automatically get urea-pressure, under the empire of which the kidney ultimately gets rid of the quantity of urea which it has to excrete.

It will be seen, therefore, that the molecules of urea accumulating in the blood tend in an opposite direction to that followed by the molecules of sodium chloride in accumulating in the tissues. This fact enables us to understand why it is that chloride retention so often culminates in hydropiginous

uræmia, while nitrogenous retention, of whatever degree, determines a *dry* uræmia. In a renal patient who remains purely ureocæmic the disease may run its whole course without the slightest tendency to oedema.

The ureocæmic patient usually displays progressive loss of appetite, which may be regarded as a defensive reaction against excess of food; there may be a mental state varying from torpor to actual coma, but the visceral and nervous disturbances are often very difficult to distinguish from those dependent on chloride retention, especially as the patient may be suffering from both. We have pointed out that in retention of urea it tends to accumulate in the blood, so that the presence of an excess of urea in the serum will afford us the most trustworthy test of urea retention. In patients with marked chloride retention the blood may only contain a comparatively small proportion of urea—say, 2 grains to 4 grains to the pint of serum, and when this is the case we know that we are dealing with chloridæmia. When the blood contains upwards of 8 grains to the pint, we have to reckon with nitrogenous retention, while if the proportion of urea rises to 25 grains or 30 grains to the pint—which is rarely seen except towards the end—the fact justifies the gravest prognosis. All this goes to prove the importance of periodically estimating the proportion of urea in the blood withdrawn by wet cupping or venesection, procedures which are so frequently indicated in the course of Bright's disease.

We are all familiar with the difficulty attending prognosis in uræmic states. One patient, who is the subject of multiple oedema, dyspnœa, vomiting and eclamptic attacks, who, in short, presents symptoms of the utmost gravity, suddenly takes a turn for the better and recovers, while another patient who is simply somnolent or suffering from loss of appetite suddenly develops the terminal coma. Now, in such cases our only guide is the proportion of urea contained in the blood. However extensive the oedema may be, and however grave the symptoms, if the blood only contains a normal quantity of urea, we are dealing with chloride retention, in which all we have to do is to adopt the dechloridation cure with diuretics.

Whenever the symptoms lead us to apprehend nitrogenous retention, the quantity of food must be cut down, and the loss of appetite in such a patient of itself suggests less meat.

Some patients take readily enough to a saltless diet, while others after a time find it intolerable. With regard to the latter, I find that if we allow them 15 grains or 20 grains of salt a day, on the plate, even this small quantity enables them to relish their food after being deprived of it altogether for some time.

The dechloridated diet entails no drawbacks in nephritic subjects, even when persevered with for long periods, since the privation of salt is always relative, not absolute. The organism only parts with very small quantities of its salt, so that a very trifling daily addition suffices to maintain the balance. I have had under observation patients who have gone on for many months on half a drachm of salt a day without the supervention of any disturbances that could fairly be ascribed to salt privation.

The dechloridated *regimen*, while enabling us to get rid of the chlorides in the organism and preventing its retention, enables the physician to apportion the intake of water and the three fundamental substances—*e.g.*, fats, carbohydrates and albumen. The ordinary healthy man may take more alimentary chloride every day of his life without inconvenience, but the renal and cardio-vascular

subject must always keep an eye on his chloride intake, and must always bear in mind the likelihood of accumulating reserves of chloride in his tissues. It follows that, independently of periods of renal insufficiency and asystole, a renal patient should take as little salt as possible with his food, for he never knows at what precise moment the exaggerated ingestion of the chlorides may prove mischievous.

## PROGRESSIVE MEDICINE AND THE OUTLOOK ON TUBERCULOSIS. (a)

By R. W. PHILIP, M.A., MD.,  
F.R.C.P. AND F.R.S.E.,

Physician to the Royal Infirmary, Edinburgh, and to the Royal Hospital for Consumption.

THE lecturer prefaced his instructive address by remarking that no subject in medicine had wider interest, and no assembly could appraise, as that great Association had, its significance and magnitude. They knew its difficulties, and had to face them every day. He was influenced, too, by the fact that the Association met that year in Ireland, where, thanks to the admirable energy of her Excellency the Vicerine and the generous co-operation of the medical profession, a great anti-tuberculosis movement was in progress. Nor could he forget the striking part played by the city of Belfast in times gone by through the remarkable labours and writings of Dr. Henry MacCormac, and in more recent times by those who were yet with us. Proceeding, the speaker gave a retrospect of the general attitude towards consumption thirty-five years ago, from which he asked them to turn and view the bounding, surging movement which had compelled the great march forward. He divided the thirty-five years since into five lesser periods of seven years each, indicating the results of observation and research. To-day the physician and sanitarian had joined hands, and had been aided not a little by thoughtful social workers who recognised the vast part played by tuberculosis as an agent of national devitalisation and impoverishment. The nations of the world were falling into line. Repeated international congresses had borne excellent fruit. With exchange of ideas endeavour had become better directed and more uniform. The significance of organisation and co-ordination of effort was gradually being appreciated. Administrative control was taking practical shape. And so the great work went on. He invited them to pause for a brief hour and think what the discovery of the tubercle bacillus had meant to medicine and to the world, and what it might mean. The determination of the essential cause had called order out of chaos. It had thrown to the winds the vague, nebulous talk of dualism which long perplexed medical science. Tuberculosis, however various its aspects, was one indivisible entity, dependent essentially on the presence and activity of one organism. Behind the changing pathological and clinical appearances the tubercle bacillus remained single and constant. The discovery had taught them to call things by their proper names. In presence of tuberculous infection, mysterious inflammations, formerly named in misleading fashion pneumonia, broncho-pneumonia, pleurisy, and bronchitis, were getting their proper place. They were facing the fact that tuberculosis was vastly more common and infinitely more various in manifestation than they dreamt of in years gone by. They had come to

realise that when tuberculous disease was present in an organ, be it in the lungs or elsewhere, they had to deal with a specific disease the local manifestation of which might be comparatively unimportant compared with the systematic effects. After dealing exhaustively with the questions of diagnosis, prognosis, and treatment, reference was made to tuberculin. Dr. Philip testified to its value and freedom from risk, and referring to the frequent occurrence of tuberculosis in children, quoted statistics to prove that the increase from the first year to the fourteenth rose steadily from 15 per cent. to 70 per cent. These figures were from the city of Vienna. The returns were from post-mortem results, and tuberculin results ranged from 16 per cent. to 68 per cent.; while of 509 consecutive patients in hospital for diphtheria, scarlet fever, and other acute infections, except measles, 271 were positive, that was circa 50 per cent. Tuberculosis was commonly contracted in childhood. The significance of that could scarcely be exaggerated. In answer to the query, Where does the bacillus come from? it was natural and tempting to trace infection in childhood chiefly to infected milk supply. But did the facts bear this out? Tuberculin tests showed that tuberculosis was relatively less common during the first two years—when, if milk were the chief agent, they might expect it to be greater—and evidence of infection became progressively common as age advanced. The facts of comparative ethnology tended also to qualify the view. For tuberculosis flourished abundantly in not a few countries where feeding with milk from cows or other animals appeared unknown. The facts appeared to point conclusively to the relatively airless

### CONDITIONS OF HOME AND SCHOOL LIFE

as a chief ætiological factor. He ventured the suggestion that it was to the extensive distribution of tuberculosis in childhood that they must trace the frequency of the graver symptoms and complications which occurred in such infections as measles and whooping-cough. Statistics testified to the tremendous grip which tuberculosis had obtained on the race and its immense ramifications throughout the social organisation. They emphasised the significance of measures directed to the better sanitation of dwellings and schools as well as workshops and offices. They illuminated and illustrated the housing question—using the phrase in the widest sense—as nothing else could do. No less did they accentuate the great need which existed for an organised and co-ordinated plan of operations in relation to tuberculosis as it occurred in our social communities. With so great a mass of tuberculous material to handle they could not afford merely to wait and treat individual patients as they happened to present themselves at outpatient departments. They must search for them in their hiding places. They must track them to their breeding-grounds. The lecturer next emphasised the need for concerted action, justifying notification and the establishment of the consumption dispensary as a central institution. The State and various administrative bodies should recognise that tuberculosis was a social evil. Ireland, thanks largely to the attitude adopted by her Local Government Board, was in possession of a Tuberculosis Prevention Act which became effective on the first of the present month, and which gave her potentially the entire machinery for a complete and effectual campaign. He invited them to consider briefly two aspects of treatment. The first of these had no direct relationship with the tubercle bacillus—namely, aërotherapy. The second depended essen-

(a) Abstract of the Address in Medicine delivered at Belfast before the British Medical Association, Wednesday, July 28th, 1909.

tially on the bacillus—was, indeed, the outcome of our growing acquaintance with that and other organisms. He referred to tuberculin and vaccine-therapy. His thoughts turned in that direction because of Belfast, and because of Henry MacCormac, and because of the misunderstanding which still lingered round the great truth he sought to establish, with the result that what ought to be a mighty bearing column was still lightly discussed as almost of doubtful purpose in the edifice. Facts and statistics had speedily accumulated which went to show that tuberculosis resulted chiefly from the exclusion or insufficient supply of fresh air in the dwelling-room, workroom, and other haunts of man; and, further, that in proportion as the supply of air and sunlight was improved, under better conditions of sanitation, there followed a corresponding reduction in the mortality from tuberculosis. Not only this, but there was abundant evidence that open-air treatment was successful in proportion as it was carried out completely, in winter no less than in summer. Indeed, there was not wanting support for the belief that the results obtained under open-air treatment was fully better during the colder than the warmer months of the year. *Aërotherapy* was a measure of universal applicability in all lands. There was no climate specially favourable for its practice. It might be doubted whether any climate, taken as a whole, was more suitable for the purpose than that of the United Kingdom. Again, *aërotherapy* was of universal applicability in every sick-room. It was not a special system to be practised in special institutions. It was utilisable in the bedroom of the ordinary dwelling as certainly as it was in the ward of a special hospital. *Aërotherapy* while specially indicated in tuberculosis, was a measure of widest applicability in relation to disease. It was a mighty principle of treatment both from the curative and from the preventive point of view. They were only awakening to the full significance of that great cleansing, antidotal, and vitalising principle whose applicability in medicine was no less far-reaching than that of asepsis in surgery. It was to the everlasting credit of Henry MacCormac that he had a clear prevision of so much of this, and had the courage and determination to state his belief in no uncertain way, notwithstanding captious criticism and even ridicule. A few sentences quoted from different pages of his work on consumption would illustrate sufficiently his width of view. From start to finish the volume contained pregnant statements of remarkably striking character, as, for instance:—"Tubercle is simple impossible in the case of persons who respire habitually air not prerespired, and who sleep in an atmosphere incessantly renewed. . . . Pure respiration is the law of life, impure respiration is the law of death. . . . It was once a general prepossession that taking cold, that damp night air, forsooth, was a source—the source, indeed—of consumption, but this is a great error. The coldest, dampest air does not, never did since the world began, and never will, induce consumption. . . . If a person will but occupy three or four hours daily with active open-air life and effort, and sleep in a chamber the windows of which shall be pulled down winter and summer the night through, he may bid defiance to consumption and scrofula for ever and ever. So all-important is the respiration of a pure unprebreathed atmosphere all night long, that I should freely stake the prospect of health upon its observance alone, before and beyond any and every other means, which omitted this most desirable and, indeed, indispensable requirement. . . . If the inhabitants of Great

Britain and Ireland would but consent day and night to live in a pure, unprebreathed atmosphere, it would put a total close to the ravages of consumption and scrofula, white swelling, tabes mesenterica, water on the brain—in fine, the whole abhorred family of tuberculous disease." Then, in relation to the bearings of climate, how modern he was:—"There is, in fact, no panacea in Californian air, no peculiar specific for lung troubles. If we cannot have the summer of California or the winter of sunny Mexico, we possess not the less a climate, whatever some may choose to say against it, replete with almost every possible element of vitality and well-being. We have air as pure as any obtainable on Californian or Mexican hills, air abounding in oxygen and ozone, air, in short, which, if we do not respire it twice, leads to as perfect security from tubercular disease here as there. . . . The shores, almost any of them, of our islands, our mountain slopes and airy downs, our many heaths and moors, will often, if not most times, prove preferable to, while they are much more accessible than is, any Nice, or Rome, or Madeira. The materials for the possible recovery from phthisis, I repeat, lie around every door." Those were remarkable words—the sayings of a seer, the writings of a prophet. Reading them to-day, he could not refrain from congratulating Belfast and reverently saluting Henry MacCormac. Having dealt with vaccine-therapy, Dr. Philip asked what of the larger future? Might they look forward with confidence to the time when tuberculosis should cease to be? He thought they might. Everything pointed to its early and final disappearance. That should not be impossible of achievement within a generation or two among the nations which regarded the public health as an integral part of civilisation. Was not tuberculosis chiefly the expression of partial, ill-informed civilisation? It was introduced by ignorant, unthinking mankind, and mankind, educated and thinking, could expel it. In the wider sense the principles of anti-tuberculosis warfare were clear enough. The chief difficulty lay in their practical application—especially their engraftment on the older *régime*. In conclusion, the speaker dwelt on the need for proper housing, wide streets, open spaces; and what applied to the towns applied no less to country districts. The ravages of tuberculosis constitute

#### A BLOT ON OUR CIVILISATION.

It is time that they inaugurated a policy commensurate with the evil and worthy of the age. It was time that they grasped the larger conception of tuberculosis as not merely the cause of an overwhelming mortality and infinite distress, physical and economic, but also a great devitaliser of the race, indirectly responsible for an incalculable amount of other disease. So soon as that was realised, and also that the agencies which conditioned its occurrence were as certainly removable as those which led to typhus, they should act effectually. Never were the causes of a disease so definitely ascertained. What was chiefly needed was the awakening of the educated intelligence of the nation and the belief that the end was attainable. When that had been achieved, the offices of the doctor would be placed on a higher plane. Instead of being asked merely to tinker up diseased frames, he would be recognised as a nurseryman in the garden of health. Was it too optimistic to anticipate the time when the physician should have restored to him his proper *métier* of physical "educator"—in the largest sense—and guardian of the national health?

## OUT-PATIENT'S ROOM.

### PADDINGTON GREEN CHILDREN'S HOSPITAL.

#### *Fracture of the Lower End of the Humerus.*

By ARTHUR EDMUNDS, M.S., F.R.C.S.

AMONGST the out-patients was a girl, *æt.* 7, who complained that she had fallen downstairs and hurt her elbow. On examination it was found that the point of the elbow was carried backwards and inwards. There was a considerable amount of swelling and pain, but there were no symptoms of pressure on any important vessels or nerves. A skiagram showed that there was a separation of the epiphysis on the outer half of the bone joining a fracture through the diaphysis extending upwards and inwards. Mr. Edmunds said there were several points in connection with separation of the epiphysis. In the first place, a pure epiphyseal separation is very rare, especially in this situation, the line of separation usually extending into the bone on the shaft side; indeed, even in cases which would be called true epiphyseal separation, the line of cleavage is between the epiphyseal cartilage and the shaft, and it is very rare to find the cartilage without a few small spicules of bone adhering to it. In the second place, the epiphysis itself is also occasionally broken. The most interesting point is, of course, the one of treatment. Generally speaking, this is satisfactory, although it may be a considerable time before the full movements of the limb are restored. The question that always presents itself is whether the fracture should be operated on or not. The complex character of the articular surfaces of the elbow demand that reduction of any fracture should be extremely accurate, as otherwise movement of the joint is greatly restricted. In young children, however, it must be remembered that the lower fragments are extremely friable, and any attempt at wiring may be impracticable, the fragments being too small and too soft to hold. In adults, on the other hand, wiring often yields the most satisfactory results. In the present case it was decided to take the child into hospital, and to attempt reduction without an open operation, and, in the event of this failing, to cut down upon the joint, for, although the fragments might be too small to wire them in position, it might yet be possible to reduce the deformity and to maintain the fragments in a good position by appropriate splinting.

The child, after admission, was *anæsthetised*, and, by extending the limb and making slight traction, it was possible to bring the lower end of the humerus into line with the shaft. By acutely flexing the limb and pushing the lower fragment outwards, quite a good position seemed to be obtained. A bent posterior splint of poroplastic felt was applied, supplemented by a triangular piece of wood on its inner side so as to prevent the lower fragment slipping inwards. The arm was then fastened to the child's thorax, with the hand touching the opposite clavicle. This was left undisturbed for ten days, and the child, who had meanwhile left the hospital, was brought to the out-patients' department for further treatment directed towards the prevention of a stiff joint. Impairment of movement in the cases, Mr. Edmunds said, may be due to one of three causes: first, imperfect apposition of the bones, so that they impinge on each other in attempts to move the joint; this, of course, is incurable by any means short of re-setting the fracture or excising the projecting portions of bone; secondly, adhesions, either between the joint surfaces or in the inter-muscular plane; this can be overcome by early massage and movements; thirdly, the formation of callus; this, he thought, was important, because in injuries about the elbow-joint, no matter how carefully the fragments are brought into apposition, this will form and give rise to a limitation of movement which will only disappear as the callus absorbs, and it is useless to attempt to overcome the resistance of the callus. In the present case movement under an *anæsthetic* was carefully carried out two or three times a week, until, at the end of the third week, the child was encouraged to move her arm for herself, care being taken, until the splints were removed, to keep the arm acutely flexed. The lower end of the humerus bears

two fossæ, Mr. Edmunds pointed out, one to receive the olecranon and one the coronoid process; if the arm be put up flexed, the olecranon fossa becomes fixed with callus, and extension is limited; if the arm be put up extended, the coronoid fossa is filled up and flexion is limited. Full extension is not a common position of the arm, and loss of a few degrees of extension is of no practical importance; if, however, the arm cannot be flexed more than to a right angle, its usefulness is greatly impaired. For this reason, apart from any considerations of the best method of keeping the fragments in position, these fractures should be put up flexed, and in practice it is found that an arm with 90° of movement at the elbow-joint, the extreme extension being an angle of 135° and the extreme flexion an angle of 45°, is a very useful limb, and a child can be trusted to use it, and hence restore rapidly full mobility.

## OPERATING THEATRES.

### ST. MARK'S HOSPITAL FOR DISEASES OF THE RECTUM.

TWO CASES OF PARA-SACRAL EXCISION OF THE RECTUM, ILLUSTRATING THE DIFFERENCE IN THE TREATMENT OF THE PROXIMAL END OF THE BOWEL.—MR. SWINFORD EDWARDS operated on a man, *æt.* 38, who had suffered with symptoms of rectal mischief for about six months. Examination revealed a typical malignant adenoma lying in the front part of the rectum; the lower border reached to within half-an-inch of the anal canal; the circumference of the growth was about equal in size to that of a five-shilling piece; it was movable, and a digital examination could detect no enlarged sacral glands. It was, therefore, Mr. Edwards considered, a favourable case for excision. The patient having been *anæsthetised* and turned into the left lateral decubitus, the pelvis being somewhat raised by a small, hard cushion placed under the left hip, a central median incision was made from about the middle of the sacrum to within an inch of the anus; this exposed the lower part of the sacrum and coccyx, which bones were then freed by lateral dissection, cutting through a few fibres on either side of the gluteus maximus. The tip and sides of the coccyx were now freed from the peri-rectal tissues by blunt, curved scissors. The freeing of the anterior surface of this bone and of the lower portion of the sacrum was completed by stripping off the soft parts by means of the finger, covered with gauze. The sacrum was divided by mallet and chisel about three-quarters of an inch above the sacro-coccygeal articulation, and the portion of bone removed after dividing the lower part of the great sacro-sciatic ligaments on either side by means of the rib shear. After ligation of a couple of the anterior sacral vessels, the incision over the rectum was deepened in its lower part by division of the fibres of the levator ani. Blunt dissection with the finger on either side of the rectum enabled the operator to reach the peritoneum, which was at once opened, and a fold of gauze passed from side to side, thus allowing the rectum to be pulled partly out of the wound. A couple of intestinal clamps were now placed on the bowel, and the fold of gauze removed. The rectum was next divided transversely between the two clamps, and the mucous membrane of the two ends thoroughly disinfected by swabbing with strong carbolic acid. The upper end of the bowel, together with the retaining clamp, was now turned upwards out of the way, and the lower end freed by further dissection from the base of the bladder and the prostate down to the level of the internal sphincter, and excised transversely. In this way a section of the rectum about 3 in. long, including the neoplasm, was removed. As the lower portion of the bowel left was too short to carry out a satisfactory rectorrhaphy, and also on account of the difference in the lumen of the upper and lower segments, the operator decided to remove the mucous membrane of the lower segment after forcible dilata-

tion of the sphincters, and, after further freeing the proximal end, to pull this down through the muscular coat of the lower segment and unite it to the anal margin. Accordingly, by a little extra dissection and slitting up the peritoneum on either side, the upper portion was rendered sufficiently loose to be brought down to the anal margin without undue tension. The opening in the peritoneum was now closed by fine continuous silk sutures. Mr. Edwards then turned his attention to the removal of the mucous membrane of the distal segment, which in this position of the patient presented some slight difficulty, but, this having been done, the proximal end was drawn down through the sphincters and sutured to the skin around the anus by interrupted silkworm gut sutures. The divided levatores ani were next sutured with fine silk, and the posterior wound closed, allowing only room for two rubber drainage tubes.

The second patient was a woman, æt. about 50, who was troubled in much the same way, having an adenocarcinoma of about the same size situated on the antero-lateral wall, but not extending so low down—in fact, in this case there was about an inch between the lower border of the growth and the upper border of the anal canal. Mr. Edwards followed the same steps as in the previous operation until dealing with the upper and lower ends of the bowel, which he united, after having closed the peritoneal cavity by through-and-through sutures of fine silk, supplemented by a series of Lembert's sutures.

Mr. Edwards said that, before comparing these two cases, it would be noticed that, in operating on the first one, he met with some difficulty in removing accurately the mucous membrane of the lower segment, owing to the position in which the patient was placed. He said that in the future, for carrying out a like operation, he would, in commencing operative interference, place the patient in the lithotomy position, when it would be a comparatively easy matter to remove the mucous membrane from the lower two or three inches of the bowel, as is done in Whitehead's operation for piles. This would be in cases where it was possible to preserve the sphincters. The patient would then be turned on the side and the operation proceeded with in the manner he had just employed. In comparing these two operations it would, he said, be noticed that by the first method all fouling of the wound by the motions was avoided during convalescence, but sloughing of some portion of the lower end of the bowel is apt to take place owing either to tension or to some interference with the blood supply in thoroughly freeing the bowel in its upper part. In the second operation, although the bowel invariably gives way behind, thereby forming for a shorter or longer period a fæcal fistula, this usually heals without any plastic operation, and it has the advantage that, during the operation, the upper segment does not require to be freed so extensively, and therefore risk of sloughing is not so great, and the operation is not so prolonged. He is therefore in favour of rectorrhaphy being carried out where the growth allows of retention of a sufficiently long lower segment.

Both cases followed the normal course. In the first the bowel did not hold in its entire circumference, some of the stitches cutting out, but this made but little difference to the patient, who had no difficulty whatever in passing his motions through the new anus. The dorsal wound healed rapidly, and he left the hospital after a month, being advised to present himself weekly for the passage of a bougie, as there was some tendency to stenosis about one inch up, where the bowel had partly sloughed. In the other case, the rectorrhaphy broke down in the posterior part of the bowel, and for a couple of weeks the greater part of the motions passed out through the wound; but this rapidly improved, and when she left the hospital five weeks after the operation, all the fæces passed through the normal anus, whilst the dorsal wound was healing satisfactorily—in fact, its complete healing might be expected well within another month. In this case, again, it was found necessary to pass a curved metal bougie every other day in order to treat the spur which always, as pointed out by Mr. Edwards, forms anteriorly at the site of the junction of the upper and lower segments.

## CORRESPONDENCE.

### FROM OUR SPECIAL CORRESPONDENTS ABROAD.

#### GERMANY.

Berlin, August 1st, 1909.

At the Verein für Innere Medizin, Hr. H. Senator introduced the subject of

#### "AIRPEARL" BATHS.

He first spoke of the action of carbonic acid baths, the beneficial effects of which were due, according to the Senator-Frankenhäuser theory, to a thermic contrast, carbonic acid being a worse conductor of heat than water. The point of indifference—that was, the point at which neither heat nor cold was experienced—was 35° C. in ordinary water, and 24° in water saturated with carbonic acid. In a carbonic acid bath, as was well known, the acid settled on the whole surface of the body in countless numbers of minute globules, and it was between the parts of skin occupied by the globules, and not under the globules themselves, that the thermic contrast was felt. Oxygen added to a bath acted in a similar manner, but to a lesser degree. Atmospheric air possessed properties similar to those of oxygen, and it was now made use of for baths. The pump that drove the air into the water was driven by water-power. As regarded the action of the baths, the CO<sub>2</sub> baths raised the blood pressure, lowered the pulse rate (?), and acted as a stimulant. The airpearl baths, on the contrary, lowered both blood pressure and pulse rate, and acted as calmatives. Oxygen baths had a similar effect. According to recent researches, CO<sub>2</sub> was resorbed through the skin, and some of it resting on the surface of the bath was inspired. Probably the same thing took place in the O baths, but no definite conclusions had been arrived at on the subject. The CO<sub>2</sub> bubbles had a more stimulating effect on the skin than the air bubbles. There was no essential difference between the O baths and the airpearl baths.

Therapeutically, airpearl baths were indicated when a calmative effect was desired, and when a lowering of the blood pressure was called for, as in arteriosclerosis.

Hr. Laqueur remarked that, from investigations made in v. Noorden's wards in Vienna, no absorption of O took place from O baths.

Hr. Gudzent communicated some notes on the behaviour of

#### URIC ACID AND ITS SALTS IN BLOOD SERUM.

He remarked, first, that His and Paul had recently again taken up the study of uric acid and its salts. There were three questions awaiting answers: (1) The solubility of uric acid in the blood; (2) their combinations in the blood; (3) the cause of the precipitation of urates. Previous representations on these points had been erroneous; the speaker's own investigations had led to widely different conclusions. Uric acid was a very weak acid, and it was worth while to learn its behaviour in mixtures resembling blood serum. It was to be advanced as a preliminary that uric acid, according to its strength, entered into conflict with other acids of the blood for possession of their bases. This conflict had no outlook as far as the stronger acids were concerned; their bases could not be detached from the far stronger acids, hydrochloric and phosphoric. It was different with CO<sub>2</sub>, which was a weaker acid than uric acid, the latter taking from the former 95 per cent. of its sodium. It then formed a sodium salt, a monosodium urate. There were in natural blood serum still unknown bodies that might influence chemical processes; a monosodium urate would here be formed. According to his experiments, uric acid entered into no other combinations, not even with colloidal substances.

In regard to pathology, there were two questions to be answered: (1) How did uric acid behave in pathological conditions? and (2) how was the behaviour of the monosodium urate in the tissues to be explained? Regarding Question 1, he would say that if the monosodium urate was not quickly expelled from the blood, if there was any hindrance to its departure, from

being in a soluble condition it might become insoluble. This was the case in gout. If, then, there were more salts in the fluid than were in solution, if the fluid was over-saturated, the salt was precipitated. According to his investigations, the blood serum was over-saturated with the monosodium urate in cases of gout. The purin-weak diet ordered for the gouty was therefore justified. In cases of damaged kidney, with its retarded excretion, the blood serum was very easily overloaded with uric acid.

As regarded the preference shown for some joints where the deposit of uric acid was concerned, this must be due to irritation after trauma. The preference of cartilage as a place of deposit was due to the fact that the cartilage was the tissue that was the richest in sodium. The assumption of Brugsch that there was a special affinity of the cartilage for uric acid was incorrect.

The speaker had found radium emanations a means of preventing the conversion of monosodium urate into an insoluble form; the salt became more soluble under their influence. It would be the work of the klinik to study the influence of the emanations on the patients themselves.

In reply to various speakers, Hr. Gudzent said that he had purposely refrained from drawing far-reaching conclusions; he had only stated the results of his inquiries; no hypotheses had been proved, but they might well stimulate to further investigations.

### AUSTRIA.

Vienna, August 1st, 1909.

#### POLIOMYELITIS.

At the Gesellschaft für Innere Medizin, Marburg presented a child from Hamburger's ward who had fallen on its arm and produced poliomyelitis. After the fall all the extremities were affected, the legs with a spastic form, the arm relaxed and powerless. The spastic form soon disappeared after admission, but the arms remained paralysed. The electric current was negative, or greatly reduced, while the reflex was increased. The sensibility was generally reduced, but in the arms it was normal. Along with this condition there was ptosis and mydriasis.

Zapparet asked if he had eliminated the possibility of a blood clot in the spinal cord. Marburg replied that the sensibility would have been greatly increased if this had been present, whereas, on the contrary, it was reduced and only normal in the arms.

Neurath remarked we often meet with poliomyelitis in the arms when a part of the pyramidal is interfered with. With this we get an increase of the deeper reflex in the lower extremities, or a positive Babinski phenomenon.

#### LUPUS AND MEASLES.

Pollak presented a little girl with disseminated acute lupus, which appeared after an attack of measles. The efflorescence reminded one of papular necrotic tubercles, although no symptom of tubercle was present. These acute lupoid patches appear to have been excited by the morbilli poison.

Nobl remarked that imperfect yellow patches could be seen on the trunk under the skin, which he thought had every appearance of tubercular infiltration, which would finally produce atrophy of the skin.

#### OBLITERATION OF DUCTUS CHOLEDOCHUS.

Goldreich exhibited a preparation taken from a child showing the total obliteration of the gall-duct, which appears to have been congenital. From birth the child was icteric, and the stools acholic. Later it was seized with panophthalmitis and sepsis, from which it died in the seventh month.

The post-mortem showed that the ductus choledochus and ductus hepaticus were quite obliterated.

#### SANATORIA FOR TUBERCULOSIS.

Escherich next introduced the subject of curing tuberculosis by sanatoria situated at great heights. The town of Leysin, in the northern region of the "Rhonetales," was 1,300 metres above the level of the sea, where a colony of tubercular invalids rapidly improved. The aspect was southern, well-protected by hills, the air being 40 to 50 C. in the summer and 20 to 30 in the winter. The sun was intense and cloudless. During eight months of the year

the surroundings are covered with snow, the temperature below freezing-point, while the thermometer in the sun is 30° C. This radiation is of great value in surgical cases, of which there have been 500 treated this year. Open wounds and tubercular fistulæ rapidly heal when exposed to the sun's rays, necrotic tissue becoming mummified and fistular ulcers healing up in a short time, while the whole surface becomes deeply pigmented as a favourable prognostication of future recovery.

Monti gave a historical review of his experience of heliotherapy during his residence in Leysin. It was while on a visit to the Engadine, and seeing the happy results of Bernhard, that the happy idea of establishing a surgical sanatorium at a high altitude, where tubercular wounds could be treated was first suggested. Rollier fixed on Leysin as a suitable situation, which has been justified by the results obtained in his klinik. The wound is left exposed to the sun, and the patient left in the open air. He then showed a few photographs of old tubercular sores that would not heal in Vienna, but with these sun baths at a high altitude the wounds and fistulæ had quite dried up. Rollier has 80 per cent. of these cases cured in six to eight months.

#### RIGA DISEASE.

Kantz showed a child, nine months old at the breast, who was brought to the ambulatorium a few days previous with a history of a swelling having commenced under the tongue 14 days before seeking admission. The child had always been healthy, and cut its first teeth when six months old.

In the frænulum linguæ was a large, clear swelling covered with a fungus. Around the base a red greyish annulus, hard and resisting, was present.

According to many authors from whom he quoted, this was a fibroma sublinguate, or what has recently become known as Riga disease, being very common in that district.

Pollak thought these fibroma arose from the irritation of the cutting of the incisors and feeding at the breast. The therapy in these cases is patience, as it may go back itself, but, if removed, will recur.

## SPECIAL REPORTS.

### THE SEVENTY-SEVENTH ANNUAL MEETING OF THE BRITISH MEDICAL ASSOCIATION AT BELFAST.

JULY 23RD TO 30TH.

[FROM OUR SPECIAL CORRESPONDENT.]

THE Seventy-Seventh Annual Meeting of the British Medical Association has come and gone, and has been a marked success. The numbers have been far higher than was expected, and strained local accommodation to the utmost, but happily not to breaking point. At the last meeting, twenty-five years ago, 563 members registered, and at this the numbers ran up to about one thousand. The addresses and sectional proceedings have attained a high level of scientific value, and the social functions, both public and private, have been planned and carried out on a generous scale, which has maintained the best traditions of Irish hospitality. Undoubtedly, the presence of Their Excellencies the Lord Lieutenant and the Countess of Aberdeen did much to add to the interest of the meetings, for they not only attended as many of the social gatherings and entertainments as could be crowded into each day, but they also attended the President's address, the other addresses, and a number of the sectional meetings. His Excellency was already an honorary member, having been made one at the Montreal meeting in 1897, and at a general meeting of the Association held in Belfast on Thursday last, Her Excellency was enrolled as the first honorary woman member, an honour which no doubt she appreciates both as an enthusiastic worker in the cause of national health, and as a strong supporter of the claims of her sex for a recognised position in public affairs.

During the previous Saturday and Monday, the representative meeting had got through a large amount of useful work, chiefly of a medico-political character, which was carried on in private. Then on Tuesday, 27th, the regular business of the meeting began. The President-elect, Sir William Whitla, entertained the members of the Council and many prominent visitors at luncheon in the Medical Institute, where there was a brief preliminary canter in speech-making. On the same afternoon, Dr. Sinclair White, the President, handed over the reins of office to his successor, and feeling reference was made to the loss sustained by the Association through the death of the Sheffield president, Mr. Simeon Snell.

#### THE PRESIDENTIAL ADDRESS.

On Tuesday evening Sir William Whitla delivered his Inaugural Address in the Assembly Hall, and on all sides it was agreed that no more brilliant ceremony had ever been carried out under the auspices of the Association. The beautiful hall was filled, the balconies by the general public, and the ground floor by the members of the Association, the majority in academic costume, providing a riot of colour beside which a poppy bed would look dull. The waiting audience was soothed by an organ recital on the grand organ by a member, Dr. Haydn Mulholland, Mus. Bac.; then, when the occupants of the platform took their places, Dr. Dempsey, the President of the Ulster Branch, in an admirable little speech, presented the badge of office to Sir William Whitla from the local members.

The foreign and American guests and the colonial delegates were then introduced to the President by the Honorary Secretary of the Executive Committee, Dr. Cecil Shaw, and were in turn introduced by the President to His Excellency the Lord Lieutenant.

The President then proceeded to deliver his Inaugural Address, in which he welcomed the Association to Belfast, and referred to the striking growth of the town since the last meeting, then dealt with the question of medical education and the history of the Belfast Medical School. The early teachers of the school were named, and a special tribute paid to the memory of Henry MacCormac, who, he said, was not a prophet, but a seer, in the matter of the cause and prevention of tuberculosis. The present position and the future prospects of the school were described, and the great clinical advantages which it enjoys were mentioned, and some of the probable changes brought about by the establishment of the new University were discussed. The Address, which was both able and eloquent, was listened to with marked attention by the great audience. At its conclusion a vote of thanks was moved by his Excellency the Lord Lieutenant, and seconded by Sir Clifford Allbutt, K.C.B.

#### WORK OF THE SECTIONS.

On Wednesday morning the regular work of the Sections began, and was continued on Thursday and Friday. The general impression seems to be that the sectional work was excellent and extremely satisfactory, and the attendance was capital. No discussion languished, and most of them were very lively. The three addresses were much better attended than usual, that on "Progressive Medicine" on Wednesday being by Dr. R. W. Philip, of Edinburgh; that on "Surgery" on Thursday being by Mr. A. E. Barker, of London; and that on "Obstetrics" on Friday being by Sir John Byers.

Among the discussions which attracted most attention were those in the Dermatology Section by Dr. Wickham, of Paris, on "The Uses of Radium in Skin Disease"; Sir Almoth Wright's address at the opening of the Hæmatology Section; the discussion on "Compulsory Notification of Tuberculosis" in the Public Health Section; those on "Angina Pectoris and Athletics" in the Medical Section; and on "The Treatment of Tubercular Joints" in the Surgical Section, opened by Sir Wm. Macewen, F.R.S.

#### THE ENTERTAINMENTS

went off exceedingly well, and seemed to be thoroughly enjoyed by the visitors. The Royal Victoria, the Mater, and the Forster Green Hospitals each gave an afternoon "At Home," and all were crowded. The Presi-

dent and Lady Whitla gave a garden party on Wednesday to the whole Association. The

#### ANNUAL DINNER

was held on Wednesday evening, and was a great success, about 350 members and guests attending it. The speeches, of course, were good. His Excellency the Lord Lieutenant replied graciously to the toast of his health. The Bishop of Down, in most happy terms, proposed "The Association," to which Dr. J. A. Macdonald replied. Mr. Kirk presented the Golf Cup from the Ulster Medical Society, over which he presides. "Our Guests" was proposed by Sir Peter O'Connell, and responded to by the Lord Mayor, Dr. Fehling (of Strassburg), and Dr. Delavan (of New York). Sir Clifford Allbutt proposed "The President," and he in turn proposed the health of the Honorary Secretary of the Executive Committee, Dr. Cecil Shaw.

The same evening a

#### LADIES' RECEPTION

was given in the Opera House, at which Her Excellency the Countess of Aberdeen welcomed the ladies to Ireland, and the Ulster Literary Theatre performed two folk plays.

#### OTHER HOSPITALITIES.

The Lord Mayor's brilliant reception in the Town Hall on Thursday night, and the Ulster Branch Reception in the Botanic Gardens on Friday, were also among the gaieties of the week, as well as numerous minor functions, with abundant private hospitality to fill in gaps in the proceedings.

There seems to be some doubt about the place of meeting next year, and perhaps the best criticism of the meeting just over was supplied by one English visitor, who suggested, "We'll come back to Belfast!"

#### THE SECTIONS.

##### Medicine.

The first discussion in the Medical Section was opened by Dr. Tyrell Brookes (Oxford) on "The Medical Aspects of Athleticism." He dealt with athletics at school and university, considering what amount of medical supervision was necessary or advisable, as well as practicable; the dangers of athletics during convalescence; the moral aspects of athletics, and their influence on the future development of the race. He was followed by Dr. Clement Dukes (Rugby) who referred to the Greek ideal of a perfectly developed mind in a perfectly developed body, which, he said, could only be attained by exercise. Athleticism was the "intemperance" of physical exercise in the not fully developed body, and physical examination and medical direction were alike necessary to avoid this. He quoted the rules in force at Rugby, recommending them as good working rules.

Sir Clifford Allbutt said that that they were deeply indebted for years past to Dr. Clement Dukes for his teaching on school athletics—a debt much increased by that day's paper. He, for his part, was content to be Dr. Dukes' disciple in regard to school athletics. One point he wished to emphasise from his own experience, which was chiefly with young adults at the University, and that was that the influence of infectious disease, in which he would include severe colds, was an element of supreme importance. If sharp exercise were taken by boys or undergraduates shortly after an infection the heart was very liable to suffer, and he was disposed to think that in all cases of enlargement of the heart after exercise in young people, an infection had preceded the physical stress.

The Provost of Trinity College (Dr. Traill) said that he was still a vigorous athlete at 71, and speaking as a tutor of 32 years' experience, he could say something of the moral aspects of athletics, the physical and mental effect of which was the banishment of morbid desire.

Sir James Barr (Liverpool) read a paper on "The Medical Aspects of Athleticism," in which he urged the advantages of physical training in the future development of the race. He believed in the improvement of physique as a substratum for mental development. He recommended hazardous and active games for young men, reserving golf, bowls, and curling for elderly gentlemen.

Regarding the formation of character it was important to notice that it was only the last three games which seemed to be essentially associated with substantial oaths and Scotch whisky. The opinions of medical men varied enormously as to the amount of exertion needed to damage the heart. He thought that well trained muscle had a good reserve of energy, and was not easily exhausted. Under proper directions no injury, apart from accidents, need attend any of the games or contests carried on in this country, and by improving the physique of the nation they raised the health standard and the moral and intellectual character of the race. The medical profession were not always fit guides in these matters. The late Ian Maclaren, after looking over a medical gathering, had said to him that from a physical point of view they would compare rather unfavourably with a similar gathering of clerics. "Brethren, these things ought not so to be."

#### Section of Surgery.

In this Section an interesting paper was read by Dr. E. C. Hort (London) on "The Diagnosis of Cancer by Examination of the Blood." He said that operations and post-mortems showed that by present methods one case in six of cancer was missed in diagnosis, and if only the cases occurring in the first 21 years of life were taken, the disease was missed in one case in 2.3. The object of the paper was to show that it was possible to aid in the diagnosis of cancer by measuring the antitryptic power of the blood serum of patients. By the antitryptic power of the blood was meant the power that a serum had of antagonising *in vitro* the digestive activity of the ferment trypsin. This power is sufficiently constant in normal blood to be used as a standard, and is found to be raised in 94 per cent. of cancer cases. It was also raised in cases where auto-infection occurred, so was no proof of malignancy, but it was often a help in diagnosis.

#### Section of Public Health.

In this Section the President, Dr. L. C. Parkes (Chelsea) in his introductory address discussed some of the problems with which the medical officer of health is confronted, the chief of which, he said, was the urbanisation of the population. This led to several evils, the most serious being the deterioration of physique in the race. Much had been done recently to improve the lot of town dwellers, but they still suffered in many ways, and one of the chief was in the air they breathed. An enormous number of their fellow-citizens had to live in an atmosphere containing only one-third of the fresh air it ought to have. In London there was some improvement owing to the extension of the system of central heating for large buildings, and the greater use of gas for cooking.

The subject of the compulsory notification of tuberculosis was introduced in a paper by Dr. Harold Scurfield (Sheffield), where notification has been compulsory since 1903. Medical men had welcomed the Act, and the general public had not objected to it. His Excellency the Lord Lieutenant, who was present, afterwards asked specially about this point, and it appears that there was practically no opposition to compulsory notification. His Excellency said he would like to congratulate Sheffield on being so enlightened. Dr. McWalter (Dublin) strongly opposed notification. He thought that nothing would do more to create a feeling against proper treatment of tuberculosis than compulsory notification. It might be desirable where practically the whole population worked in factories and workshops, but he did not consider it desirable to introduce it all over the country. It was an interference with the liberty of the subject, and with the first principles of justice. He referred to the scare about consumption being a superstition of science. Sir Charles Cameron (Dublin) said that he did not agree with Dr. McWalter. Something must be done when there was a desperate disease, and if some inconvenience were caused to a few, it was nothing compared to the good achieved. In Dublin the deaths from tuberculosis exceeded by three times those from any other disease. Compulsory notification was also supported by Sir John Byers (Belfast), Dr. Nasmyth (Edinburgh), and Dr. Rentoul (Lisburn).

The disposal of sewage effluents in tidal waters was discussed by this Section on another day, the local conditions which have caused so much trouble and outlay in Belfast being well described by Dr. Henry O'Neill and Professor Letts. The discharge of great quantities of sewage into the sluggish tidal waters of Belfast Lough gives rise to trouble in two ways: it promotes an enormous growth of green seaweed, *Ulva Latissima*, which is cast up on the shore and there decays, giving forth sulphuretted hydrogen as it does so, and thus contaminating the air of the whole neighbourhood; and, secondly, it encourages the production of shellfish in the Lough, and these being full of sewage are frequently a source of poisoning to the lower classes of the city, who consume them in quantities if they can get them. The discussion was continued by Dr. Wilson (Belfast), Professor Dunbar (Hamburg), Sir Peter O'Connell (Belfast), Dr. Carnwath (Manchester), and the President of the Section, all agreeing as to the great difficulty of the problem.

#### Psychological Medicine.

In this section a paper which attracted much attention was read by Dr. W. R. Dawson (Finglass, Co. Dublin) on the Report of the Royal Commission on the Care and Control of the Feeble-Minded. The paper was of a technical character, and necessitated familiarity with the Report, which it criticised in a number of details, accepting most of its general principles. Dr. Shuttleworth (London), Dr. Maguire (Belfast), and Mr. Fagan (H.M. Inspector of Industrial Schools in Ireland) joined in the discussion. The last-named said that about 5 per cent. of the children under his care were mentally defective, and in these cases good results were obtained by the system of giving the children a practical manual education, instead of the usual school curriculum.

## LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

### "WITHOUT JUSTIFICATION."

To the Editor of THE MEDICAL PRESS AND CIRCULAR.  
THE following is reprinted from *The Times*, July 30th, 1909:—

"To the Editor of *The Times*."

SIR,—The attempt, mentioned in *The Times* of to-day, that is to be made to raise £35,000 in order to remove the National Hospital for Diseases of the Heart, which contains 26 beds, from its present position to a new site is without justification.

The London hospitals contain upwards of 10,000 beds, and, although I have not got the precise figures, I should say that of the occupants of these beds, on any day in any year, it is probable that 20 per cent. are suffering from heart disease. In the name of reason, of economy, of medical science, and of what represents everything that is best in hospital administration, what justification is there to support this appeal for £35,000? To the best of my judgment, and I believe I shall have the overwhelming consensus of medical opinion behind me in support of this view, it would be monstrous to waste £35,000 in the way proposed in the notice on page 14 of *The Times* of to-day. The voluntary hospitals are an inestimable boon to the people of this country, though the difficulty of raising funds for their support grows harder every year; and I feel it to be a public duty to ask you to publish this protest.

"I am, Sir, your obedient servant,

"HENRY C. BURDETT.

"Porchester Square, W., July 28th."

[The above is commented upon on page 107 of our present issue.—ED., M.P. AND C.]

### THE MEMBERSHIP DIPLOMA OF THE SCOTCH COLLEGE.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Should the Edinburgh College of Surgeons not decide to grant a membership diploma, as requested by the Association of Scotch Diplomates, the Glasgow Faculty ought to be asked to take up the matter.

Some short time since the Council of the Faculty of

Physicians and Surgeons recommended, by a majority, that the title should be changed to that of "Royal College" of Physicians and Surgeons. When the question came before the Fellows it was defeated, but there is little doubt that an active agitation would soon result in a majority in its favour.

If an amendment to the charter for the purpose of altering the title were then obtained, it would be easy to get, at the same time, power to confer the diploma of member of the Royal College of Physicians and Surgeons, Glasgow.

I am, Sir, yours truly,  
F. C. McWALTER, M.D.Brux., F.F.P. and S.G.,  
Barrister-at-Law.

Dublin.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—In relation to the petition lately presented to the Council of the Royal College of Surgeons of Edinburgh *re* the qualification of Member in place of Licentiate, it may be of interest to note that in Schedule D. of the Medical Act of 1858 such qualification is actually specified, "Fellow and Member of the Royal College of Surgeons, Edinburgh," and by Sect. 16 the Registers are directed to be kept in accordance with this "Form." It may also interest you to note that I prosecuted an unqualified person last week who had assumed the title, "M.R.C.S.Edin.," and he was ordered to be imprisoned for a term in default of payment of the penalties inflicted. With respect to the amalgamation of the Royal College of Surgeons of Edinburgh and the Faculty of Physicians and Surgeons of Glasgow, this is, of course, made possible by Sect. L. of the Act of 1858.

I am, Sir, yours truly,  
A. G. BATEMAN,  
Gen. Secretary, Medical Defence Union.  
Medical Defence Union, 4 Trafalgar Square, W.C.,  
July 28th, 1909.

## OBITUARY.

PROFESSOR ALEXANDER FRASER, F.R.C.S.I.

A DECADE ago the teaching of anatomy in Dublin was in the hands of three notable men, notable as men of science and as teachers—Ambrose Birmingham, Daniel Cunningham, and Alexander Fraser. All three were in the prime of life, in the fullness of their powers, and now all three are gone. Five years ago we regretted the death of Birmingham, who, had he lived a little longer, would have seen the school he served so faithfully developed into a University department with suitable premises and equipment.

A few weeks ago we mourned the death of Cunningham, and now Fraser has gone. Alexander Fraser, Professor of Anatomy in the Royal College of Surgeons in Ireland, was born at Lossiemouth, in Scotland, in 1853. He was educated at Glasgow University, where he first took up the study of Anatomy under Professor Cleland. He thence went to Owens College, Manchester, as Demonstrator of Anatomy, and in 1883, on the appointment of Professor Cunningham to the Chair of Anatomy and Chirurgery in Dublin University, Fraser was nominated as his successor in the Royal College of Surgeons. From that time until a few months ago he devoted himself with rare assiduity to research in the subject of his life-work, and to the teaching of his classes. He made frequent communications to the scientific journals, and was a regular attendant at the meetings of the Royal Academy of Medicine. His best known work is his "Atlas of the Brain and Organs of Sense," but hardly a term passed without the publication of some memoir on an anatomic subject. In addition to his work at the Royal College of Surgeons, he was Professor of Anatomy at the Metropolitan School of Art, and he took special interest in anatomy as applied to art. In all his work, whether as a student or as a teacher, the outstanding feature was thoroughness. Superficial knowledge was his abhorrence, and he loved to give his pupils new views of anatomic relations. He taught them to dissect by unconstitutional methods, and woe to the candidate who met him with only a text-book knowledge.

As a teacher he was lucid, interesting, and painstaking to a degree. No trouble or labour was too much in making a difficult point clear to an eager pupil. His work could not fail to rouse gratitude from his classes, and at the time of his death his past pupils were busy arranging to give him a substantial recognition of his reaching the twenty-fifth anniversary of his appointment as Professor. A few months ago the Council of the College, at the annual dinner, presented him with a substantial cheque as a mark of their confidence and esteem.

It was not merely his zeal as a teacher and man of science, however, which endeared Fraser to his friends. His entire absence of self-seeking, his modesty, and his single-mindedness, secured the respect and affection of all who knew him.

Fraser's death is directly due to his unsparing devotion to work. Last spring his faithful and experienced porter died of sepsis, and Fraser, in his anxiety that his class should suffer no inconvenience, had personally to supervise the preparation of bodies in damp and unpleasant surroundings. He got a chill in such work, which gave tuberculosis a hold on his overwrought body, and in a few months his life's work was over.

## REVIEWS OF BOOKS.

THE AFTER-TREATMENT OF OPERATIONS. (a)

THIS is a very useful treatise, and leaves no question unanswered on the subject with which it deals. In his preface to the third edition, Mr. Mummery tells us that it has been necessary to make very extensive alterations and additions, and to re-write several of the chapters. The chapter on shock has been revised and brought up to date, and makes very interesting and instructive reading. Especially is the physiology of shock reviewed in a very terse and lucid manner, whilst the indications as to treatment are very properly based on the physiological facts. In the chapters on abdominal surgery the author gives some very valuable advice, not only on the after-treatment of straightforward cases, but also on the methods of dealing with the various complications which may arise, and on what is still more important—viz., the precautions to be taken for the avoidance of these complications. The chapter on post-anæsthetic complications, revised by Dr. Blumfeld, supplies the reader with some excellent hints, especially with reference to dealing with post-anæsthetic vomiting; the same remark applies to the chapter which deals with the care of patients after operations on the genito-urinary tract; this part has been revised by Mr. Thomson Walker. Serum and vaccine treatment of sepsis is dealt with in a short article, the pith of which may be summed up by the last words it contains: "The method of treatment is difficult and complicated. It can only be satisfactorily carried out by a skilled bacteriologist." Undoubtedly Mr. Mummery's little book should prove of great value, not only to the surgeon, but also to the house surgeon, and to all those medical men who have to look after the welfare of patients who have undergone an operation.

PYE'S SURGICAL HANDICRAFT. (b)

AN old friend, much grown in size, but withal rejuvenated and necessarily carried far beyond the intentions of the original author, this book forms a volume which should be of great use, not merely to house surgeons, but to every practical surgeon. In Chapter XIII. Mr. Clayton-Greene gives a short—perhaps too short—and temperate account of massage, manipulation, and passive movements in fractures in which he steers an excellent course between the rigid confinement of the old treatment and the massage combined with movement as so much advocated by some

(a) "The After-Treatment of Operations." By Lockhart Mummery B.A., M.B., M.C.Cantab., F.R.C.S.Eng. Third Edition. Pp. viii. and 251. London: Baillière, Tindall and Cox.

(b) "Pye's Surgical Handicraft." Revised and largely re-written by W. H. Clayton-Greene, B.A., M.B., B.C.Cantab., F.R.C.S.Eng. Pp. xvi. and 592. Bristol: John Wright and Sons, Ltd. London: Simpkin, Marshall, Hamilton, Kent and Co., Ltd.

surgeons at the present time. He shows us the advantages and the disadvantages of each, and every surgeon must cordially agree with him when he says:—"We would state clearly that both massage and passive movement can be overdone; this without for one moment disparaging the treatment under proper conditions." Chapter XXXVIII. deals with the minor surgery of the eye, and is by Leslie Paton. Mr. H. W. Carson has written Chapters XXXIX., XL., XLI., and XLVI., which treat respectively of diseases of the nose and throat, of the larynx and of the ear, and head injuries. Chapter XLII. gives the treatment of the teeth, and is by Norman G. Bennett. All these are evidently in safe hands; the same may be said of Chapters XLV., on the treatment of cases of poisoning, and LII., on urine testing, both by W. H. Willcox; Chapter XLVIII., on anæsthesia, by Joseph Blumfeld, and Chapter LIII., on X-rays, by G. Allpress Simmons. The work contains ten plates and 333 illustrations, all of which are of great help to the reader.

#### A MANUAL OF MINOR SURGERY AND BANDAGING. (a)

WHEN a book has reached its fourteenth edition in forty-nine years, without a break of more than five years between any edition, it may be fairly assumed to be very popular, and to have fulfilled during this period the purpose for which it was originally intended. All this can be said of this little work, which, although it has naturally increased in bulk, like the snowball rolling down the hill, is still of that handy size so convenient for those to whom it should be a boon—house surgeons, dressers, and junior practitioners. The introduction should be perused most carefully by those who hold resident appointments at any hospital, as an admirable line of conduct is traced out, which, if followed, would tend to do away with the small *désagrémens* which not unfrequently crop up in connection with these posts. If the directions Mr. Pollard gives with regard to asepsis in the operating theatre, preparation of the patient, case taking, etc., were followed out by all house surgeons, what a paradise surgeons would live in, and they could occasionally give a small sigh of contentment under cover of their gauze mask, instead of having to stifle (or not) a few selected anathemas. The manual, which contains 250 excellent illustrations and one plate, should be in the hands of all house surgeons and dressers, and, indeed, should continue to be their valued friend long after they have commenced practice.

#### ACCIDENTAL INJURIES TO WORKMEN. (b)

THE perfect book on accidents to workmen would be a very difficult, if not impossible, one to write, for not only has it to be compounded of law and medicine in varying proportions, but it must be so written that the lawyer can understand the medicine as the doctor understands the law. Moreover, there remains the intelligent layman, insurance manager, or whoever he may be, who wants guidance from both professions, and who must not be troubled too much with the technicalities of either. Among these difficulties Mr. Barnett and his coadjutors have steered a fairly successful course; indeed, it is doubtful if it is possible to do more in a work which has to cater for the three types of readers. The legal introduction is clear and well-written, but we are rather disappointed that the discussion of the important question, "What constitutes an accident?" is not dealt with more fully. What is said is sound, but could profitably be expanded. We like the definition given of an accident—for the purposes of the Workmen's Compensation Act, 1906—but we dissent from the last clause that the incident is "not a necessary accompaniment of the work engaged in." We fully admit the difficulty of definition, and think it rather courageous of the author

to tackle it, for the decisions of the Court of Appeal have widened the scope of the accident till the only definition that really covers the ground is "anything that the workman or his friends think ought not to have happened to him." It is clear from *Hughes v. Clover, Clayton and Co.*, if never before, that the incident alleged to have caused the injury may be a necessary and ordinary accompaniment of the work. A little fuller information would be acceptable, too, on the subject of compulsory operations, the effect of the Court of Appeal judgment quoted having been to a great extent nullified by a later decision that a workman is justified in refusing an operation, if one medical man advised against it. The effects of pre-existing disease, among which syphilis is one of the most important, constitute some of the gravest problems in connection with compensation claims, and Mr. Barnett rightly points out that companies will be forced, sooner or later, to institute medical examinations of employees to save them from the heavy loss occasioned by the aggravation, or alleged aggravation, of diseases by trivial accidents; such an event would be a very bad one for the workers. Regional injuries naturally constitute a leading feature in this book, but their bulk is so vast, and the subject so complex, that they are difficult to treat in all their bearings. The remarks made are sensible and suggestive, but when space is so valuable, we think that such points as the ordinary symptoms of fractures might have been omitted, and the after-results of these injuries, especially from the point of view of prognosis, more adequately set forth. The comments on hernia are good, and to the point, but we fear that hernia is almost a lost cause as far as resisting claims is concerned. There is a useful section on traumatic neurosis, and we cannot help regretting that this and the previous chapters were not extended, and the text of the Act, which follows, omitted. The latter can be bought so cheaply that it is a pity the space it occupies was not filled by amplification of the more important chapters. On the whole, though, this book is a distinct contribution to the subject with which it deals, and if the author adopts our hints in future editions, he will make his work even more useful and praiseworthy than it is at present.

## MEDICAL NEWS IN BRIEF.

#### British Pharmaceutical Conference.

LAST week pharmacists assembled at Newcastle-on-Tyne for the annual meeting of the British Pharmaceutical Conference.

The Presidential Address was delivered by Mr. J. F. Tocher, of Peterhead, in Armstrong College.

Taking as the title of his address "Some Problems of Interest to Pharmacists To-day," the President said it was in Newcastle-on-Tyne that for the first time British pharmacists met together as a voluntary assembly to discuss problems of interest to them. The institution of the British Pharmaceutical Conference as an organisation for the encouragement of pharmaceutical research in 1863, five years before the passing of the Pharmacy Act, which gave pharmacists a legal status, was an event of the greatest importance to pharmacists. Its avowed object of holding meetings in different parts of the country for the purpose of affording a periodical opportunity for pharmacists in the provinces to meet one another and discuss subjects of importance to them had ever been to the front.

The sale of patent medicines from the medical standpoint was, Mr. Tocher considered, of doubtful service to the community. British citizens spent about £4 6s. annually on alcohol, but only 1s. 4d. on patent medicines. Putting it more from the point of view of the pharmacist, he thought that if every registered chemist sold patent medicines he would draw on an average about £20 per annum from their sale. The average price of drugs and the character of prescribing 100 years ago and to-day had engaged his attention. The pharmacist paid on an average almost exactly one-half of what he paid 100 years ago for the same drugs. As far as prescribing was concerned,

(a) "A Manual of Minor Surgery and Bandaging" (Heath). By Bilton Pollard, F.R.C. Fourteenth Edition. Pp. xvii and 488. London: J. and A. Churchill.

(b) "Accidental Injuries to Workmen." By H. Norman Barnett, F.R.C.S., Surgeon, Cripple's Home, Belfast; with article on Injuries to the Organs of Special Sense by Cecil E. Shaw, M.A., M.Ch., M.D., Assistant Surgeon, Belfast Ophthalmic Hospital, and a Legal Introduction by Thomas J. Campbell, M.A., LL.B., Barrister-at-Law.

the character of the prescribing in 1810 was equal, if not distinctly superior, to that of 1909. He invited members to compare the samples he gave of both and consider whether the time had not come for a thoroughgoing agitation as to methods of prescribing. In connection with the revision of the British Pharmacopœia Mr. Tocher remarked that early in the year the Committee of Reference in Pharmacy appointed by the General Medical Council reported to the Pharmacopœia Committee the results of work done on the Pharmacopœia up to October 29th last. The recommendations appeared on the whole to be satisfactory, although it seemed to him that in certain directions the committee tended to go further than was desirable in a work issued by authority and used as a standard.

#### Royal Sanitary Institute.

THE following were admitted members during July: John A. Bisset, L.R.C.P., L.R.C.S. (M.O.H.), Boulder City, W. Australia; Douglas E. Darbyshire, M.B., Ch.B., M.R.C.S., L.R.C.P. (M.O.H.), Cottesloe, W. Australia; Walter L. Hawksley, M.B., Ch.B., D.P.H. (School M.O.), Education Offices, Liverpool; James W. Hope, F.R.C.P.Ed., D.P.H. (M.O.H.), Perth, W. Australia; Edward S. Humphry, M.R.C.S., L.R.C.P. (M.O.H.), Southern Cross, W. Australia; Launcelot M. Hungerford, L.R.C.P.I., L.R.C.S.I., L.M., Geraldton, W. Australia; Lewis E. W. Irving, M.D., C.M., D.S.O., Edmonton, Alberta, Canada; Robert M. Mitchell, D.P.H., M.B., F.R.C.S. (M.O.H.), Coolgardie, W. Australia; William M. Philip, M.B., C.M., D.P.H. (M.O.H.), Colombo, Ceylon; William P. Seed, M.R.C.S., L.R.C.P. (M.O.H.), Perth, W. Australia; J. E. Fergusson Stewart, M.B., C.M. (M.O.H.), Guildford, W. Australia; Andrew S. Young, M.B., B.S. (M.O.H.), Meekatharra, W. Australia.

#### Royal College of Physicians of London.

AT the ordinary quarterly meeting of the College, on Thursday last, the following Fellows of the College were elected officers for the ensuing collegiate year:—Censors.—Sir W. Allchin, M.D.; F. de Havilland Hall, M.D.; Seymour J. Sharkey, M.D.; J. Kingston Fowler, M.D. Treasurer.—Sir Dyce Duckworth, M.D., LL.D. Emeritus Registrar.—Dr. Edward Liveing. Registrar.—J. A. Ormerod, M.D. Harveian Librarian.—Dr. J. Frank Payne. Members of the Library Committee.—Norman Moore, M.D.; W. Osler, M.D., F.R.S.; A. F. Voelcker, M.D.; C. A. Mercier, M.D. Curators of the Museum.—Sir William Allchin, M.D.; S. J. Sharkey, M.D.; W. Hunter, M.D.; and F. W. Andrewes, M.D.

**New Members.**—The following candidates, having passed the required examinations, were admitted members of the College:—E. G. Fearnside, M.A., M.B. Camb., L.R.C.P., M.R.C.S., London Hosp.; W. E. Hume, M.B. Camb., London Hosp. and Berlin; J. Lindsay, M.D. Edin.; H. MacCormac, M.B. Edin., Middlesex; W. Malden, M.A., M.D. Camb., St. Barth.'s.; A. H. Miller, M.B. Camb., L.R.C.P., and M.R.C.S., Guy's; P. T. O'Sullivan, M.D., Roy. Univ., Ireland; L. G. Parsons, M.D. Lond., L.R.C.P. and M.R.C.S., Birmingham; and Ivy E. Woodward, M.D., B.S. Lond., Lond. School of Medicine for Women.

**New Licentiates.**—The following gentlemen, having conformed to the by-laws and regulations, and passed the required examinations, had licences to practise physic granted to them:—

R. B. Abraham, St. Thomas's; G. G. Alderson, Camb. and Univ. Coll.; F. J. Aldridge, Oxford and St. Thomas's; E. C. Alles, Ceylon, King's Coll. and Middx.; E. B. Allnutt, St. Bartholomew's; \*F. L. Angior, Liverpool; C. W. Archer, Camb. and St. Barth.'s; W. R. W. Asplen, Westminster; J. D. Benjafield, University Coll.; R. H. Bharucha, Bombay, K. Coll. and U. Coll.; T. K. Boney, St. Bartholomew's; J. M. Brito-Salazar, Caracas and Middlesex; S. S. Brook, Guy's; A. J. Brown, London; W. H. Cam, Camb. and London; A. S. Cane, Camb. and St. Barth.'s; R. S. Carey, Camb. and London; W. J. Chambers, Toronto and Middx.; K. S. Chasker, Bomb., U. Coll., K. Coll., and Middx.; H. M. McCoombs, Camb. and St. Barth.'s; M. M. Cowasjee,

Guy's; R. L. Crabb, Univ. Coll.; J. W. Cropper, Liverpool; C. H. Crump, Guy's; F. J. Cutler, Guy's; R. M. Dennys, St. Bartholomew's; G. V. Deshmukh, Bombay and London; A. MacD. Dick, Edinburgh; R. S. Doran, Charing Cross; M. A. E. Duvivier, Guy's; R. Fisher, Camb. and St. George's; R. H. W. Fisher, Camb. and St. Thomas's; A. L. Fitzmaurice, Guy's; P. L. Foote, Otago and London; J. C. Fox, Camb. and St. Thomas's; A. G. V. French, St. Thomas's; S. Gordon, Camb. and London; A. J. Graves, Columbia Univ., Char. Cross, and Middx.; J. M. Hammond, Bristol and St. Barth.'s; T. R. Harvey, Sheffield and Guy's; H. W. Heasman, Guy's; J. S. Hopwood, St. Thomas's; A. H. H. Howard, Charing Cross; D. Isaacs, Guy's; J. E. Jackson, London; G. Jefferson, Manchester; T. J. Johnston, Toronto and London; D. Kennedy, Univ. Coll.; M. H. Langford, Middlesex; \*W. Ledlie, Camb. and Guy's; R. J. B. Leney, Camb. and London; J. T. Lloyd, London; H. McLean, Camb. and London; R. H. S. Marshall, St. Mary's; B. C. Maybury, St. Thomas's; E. Mayer, Zurich and St. Barth.'s; C. A. Meaden, St. Bartholomew's; J. C. W. Methven, London; J. A. Noble, Oxford and St. Barth.'s; P. D. Oakley, Leeds; Pairs-Mall, Munich and London; W. R. Parkinson, Otago and St. Thomas's; R. A. Parsons, St. Mary's; F. C. Pridham, St. Thomas's; W. T. Quinlan, Cardiff and London; R. G. Riches, St. Bartholomew's; J. X. Robert, Toronto, London, and Birm.; H. D. Rollinson, Birmingham; L. M. Routh, Camb. and St. Thomas's; L. Russell, King's College; A. Ryland, St. Bartholomew's; I. Shorbagi, Cairo, St. Thomas's, and London; W. S. Simpson, Charing Cross; H. Smale, St. Mary's; W. J. Smith, Toronto and London; W. D. Southern, Charing Cross; C. G. Sprague, Guy's; B. A. W. Stone, Oxford and Bristol; W. W. Treves, Camb. and London; S. A. Vairakiam, Ceylon and London; J. van Schalkwijk, Camb. and St. Barth.'s; J. M. Weddell, Camb. and St. Barth.'s; T. H. Whittington, King's College; D. P. Williams, Charing Cross; S. S. M. Wood, Westminster; C. R. Woodruff, St. Bartholomew's. (\*Under regulations dated October 1st, 1884.)

#### The Irish Medical Schools' and Graduates' Association.

THE annual summer meeting and luncheon of this Association was held at the Medical Institute, Belfast, on Wednesday, July 28th. There was a large attendance of members and guests, including ladies. Sir Charles Cameron was in the chair, and amongst those present were the Rev. Dy. Thomas Hamilton, Vice-Chancellor, Queen's University, Belfast; Dr. Sinclair White, retiring President, British Medical Association; and Dr. E. Rayner, the Hon. Treasurer; Dr. Dawson Williams, Dr. J. A. Macdonald, Mr. H. A. Ballance, Mr. R. H. Kinsey, Drs. Smith Whitaker, A. Cox, Shepherd-Boyd, Buist, Mr. Guy Elliston, R. Fegan, J. H. Ewart Agnew, Rev. Dr. R. Seaver, Dr. J. J. Macan (Chairman of Council), Drs. T. Hobbs Crampton and W. Douglas (Hon. Secretaries).

#### Royal College of Surgeons, Ireland—Barker Prize.

A PRIZE of £21 is offered for competition, and is open to any student whose name is on the Anatomical Class list of any school in the United Kingdom. The preparations entered must be placed in charge of the Curator on or before April 30th, 1910. The prize is offered for a Dissection of the Cervical Sympathetic.

1. The preparations must be sent to the Curator of the Museum, Royal College of Surgeons, Ireland, each being marked with a fictitious signature, and accompanied by a sealed envelope bearing outside the same signature, and containing within,

(a) The full name of the Competitor, and

(b) A declaration to the effect that the work of the preparation has been carried out by himself.

The printed form necessary for this declaration can be obtained on application to the Curator.

2. The dissections are to be mounted in vessels fitted with glass covers, but the covers must not be sealed down. Earthenware basins and plaster of Paris settings are not compulsory if the specimens can be equally well displayed and preserved by other means.

3. No prize will be awarded unless sufficient merit

be shown, 70 per cent. of the total marks being the minimum. The following is the scale of marks:—(a) For the merit of dissection, 60; (b) for excellence of setting, 20; (c) for originality, 20; total, 100. The dissections for which prizes are awarded become the property of the College.

4. Those competitors who enter dissections for which prizes are not awarded, but which show sufficient merit, may be refunded such amount of the cost of production as the Examiners deem fit.

5. The cost and risks of transport must be borne by the student. The College will not be responsible for any damage the preparations may sustain; but those of unsuccessful competitors residing at a distance will be carefully re-packed and handed to the carriers for delivery at such address as may be specified by the student.

#### The Queen Alexander Sanatorium, Davos.

THE prospective opening of the Sanatorium for the reception of patients early in this autumn was announced from the chair at the sixth annual meeting of the Council, held at 11 Chandos Street, Cavendish Square, W., on July 16th, by the President, the Lord Balfour of Burleigh, K.T., P.C., who has laboured so long and successfully in the difficult task of raising funds. The magnificent donation of £25,000 just received from a munificent sympathiser, who desires that his name shall not be published, not only supplies the necessary balance to complete the work and to open the Sanatorium free from debt, but provides the means for its scientific equipment and for future extensions. For the present the Sanatorium will accommodate 54 patients, all in single rooms. But the public rooms are devised for a full complement of 120 patients.

The Davos Invalids' Home, the original foundation of the late Mrs. Lord, which for so many years was the only representative of our national charity in Davos, has now ended its task and fulfilled the purpose for which it was initiated—that of developing into a National Sanatorium. The Home had been granted Her Gracious Majesty's patronage as far back as 1899.

#### The Small-Pox Bacillus.

DR. OSWALDO CRUZ, Director-General of the Sanitary Service, announced recently at the Rio de Janeiro Academy of Medicine that the bacillus of small-pox, which was of animal origin, had been discovered in the course of bacteriological researches carried out at the Oswaldo Cruz Institute by Drs. Henrique Beurepaire de Aragao and Prowazek.—*Times*.

### PASS LISTS

#### University of Durham.

At the Convocation holden on Saturday, July 24th, the following degrees were conferred:—

Degree of Doctor of Medicine.—Vincent E. Badcock, M.B., B.S.Durh.; Charles W. M. Hope, M.B., B.S.Durh., F.R.C.S.; Elizabeth N. Niel, M.B., B.S., B.Hy., D.P.H.Durh.; Howard B. Stephenson, M.B., B.S.Durh.

Degree of Doctor of Medicine for Practitioners of Fifteen Years' Standing.—Thomas W. Bartlett, L.R.C.P. and S., L.F.P.S.G.; John Gay, M.R.C.S., L.R.C.P.; Henry J. Hildige, L.R.C.P. and S.I.; John L. Jeaffreson, M.R.C.S., L.R.C.P., L.S.A.; Edward S. Marder, M.R.C.S., L.R.C.P.; Joseph A. Nolan, M.R.C.S., L.R.C.P. and S., L.F.P.S.G.; Everett E. Norton, M.R.C.S., L.R.C.P., D.P.H.; Charles Reidy, B.A., L.R.C.P. and S.Ed.; Ernest Ringrose, M.R.C.S., L.R.C.P.; John G. Uppley, L.R.C.P. and S.; Alexander H. Walker, M.R.C.S., L.R.C.P.

Degree of Bachelor of Medicine (M.B.).—Wilfred Barkes, Alexander H. Bower, John G. Campbell, M.A., Harold A. Cooper, Patrick A. Galpin, Francis F. T. Hare, John P. Jackson, Theresa de G. Miller, Ruth Nicholson, Robert Raffle, Harold W. Sykes, Dorothea M. Tudor, George H. Wood.

Degree of Bachelor of Surgery (B.S.).—Wilfred Barkes, Alexander H. Bower, John G. Campbell, M.A., Harold A. Cooper, Patrick A. Galpin, Francis F. T. Hare, John P. Jackson, Theresa de G. Miller, Ruth Nicholson, Robert Raffle, Harold W. Sykes, Dorothea M. Tudor, George H. Wood.

Degree of Bachelor of Hygiene (B.Hy.).—Sydney Havelock, M.B., B.S., B.Sc., Durh.; Howard B. Stephenson, M.B., B.S.Durh.; Thomas L. Wormald, M.B., B.S.Durh.

Diploma in Public Health (D.P.H.).—Sydney Havelock, M.B., B.S., B.Sc.Durh.; William T. Sewell, M.D., B.S.Durh.; Howard B. Stephenson, M.B., B.S.Durh.; Frank T. H. Wood, M.D., B.S., B.Sc.Lond.; Thomas L. Wormald, M.B., B.S.Durh.

#### Royal College of Physicians and Surgeons of Edinburgh, and Faculty of Physicians and Surgeons of Glasgow.

THE Quarterly Examinations of the above Board, held in Edinburgh, were concluded on July 23rd, with the following results:—

The following candidates passed the First Examination:—Charles C. Forsyth, Stanley E. Jones, John McCagie, Maneckjee R. Dalal, India; Burjor M. Nanavutty, Poona; William W. K. Duncan, Frederick G. Gibbs, Edward A. Neilson, N.Z.; Charles H. N. Baker, India; Verdon C. H. Dearden, John M. Hiddleston, William Ainsley, Dani Chand, Jullimdur; Paul L. Manuel, Mauritius; Alfred Parker, James B. Donaldson; and 7 passed in Physics, 14 in Biology, and 4 in Chemistry.

The following passed the Second Examination:—Frank M. H. Sanderson, Burjor M. Nanavutty, Poona; Hugh W. M. Wallace, William Elder, James McFarlane, Charles S. Ogilvy, William C. Davis, Norman S. Williams, India; Charles E. H. Smith, Robert Trotter, James Mitchell, Cyril M. Willmott, William S. Lindsay, Hormazd A. Topalia, Bombay; Andrew Hegarty, Walter S. Durward, David W. Woodruff, Wilhelm S. Rorich, Cape Colony; Rona Lockhart, William L. Coullie; and 7 passed in Physiology.

The following passed the Third Examination:—Maneck B. Motafram, Bombay; Robert E. N. Martyn-Clark, Punjab; Edward D. Ellis, Morris Greene, Russia; Ernest J. Fisher, Prabodh C. Banerjee, India; Emmanuel P. Ghose, India; Vasudeo D. Nimbkar, India; Henry E. K. Fretz, West Indies; Singcha Hoashoo, S. America; Henry G. Lamberty, Mauritius; Charles K. Carroll, India; Charles J. Evans, Samuel E. A. Acheson, Zebina A. De Cruz, Cochín-India; George F. Walker, Philip G. Phillips, Maneckjee R. Dalal, India; Richard L. Hughes; and 1 passed in Pathology and 4 in Materia Medica.

The following passed the Final Examination, and were admitted L.R.C.P.E., L.R.C.S.E., and L.F.P.S.G.:—Edward D. Ellis, Halifax; James Reid, Belfast; Augustus J. Kelsey, Mauritius; Francis W. Milne, Helensburgh; William G. Forde, Co. Cork; John J. Huston, Ireland; Joseph Muller, Bombay; Henry G. Ramsbottom, Whalley; William Taylor, Ireland; Sydney G. Tibbles, James E. R. Ramdeholl, British Guiana; Edmund Eccles, Longridge; Maria S. Allen, Stafford; Kul Bhusham, Punjab; Edwin W. Marsh, Rangoon; Archibald C. Tait, Newfoundland; James S. J. Stenhouse, Dunedin; Jugal K. Sharma, Moradabad; McWilliams Henry, Halifax; Arthur I. Luke, India; Robert Massie, Edinburgh; Thiruchelvam Sabastian, Madras; Abhayabala Singha, Amritsar; Louis N. Robertson, Trinidad; Norman C. Shierlaw, S. Australia; Chandiprasad Trivedi, India; and 7 passed in Medicine and Therapeutics, 2 in Surgery and Surgical Anatomy, 12 in Midwifery, and 12 in Medical Jurisprudence.

#### Royal College of Surgeons of Edinburgh.

At a meeting of the College held on July 22nd, the following gentlemen were elected Fellows:—Richard W. Anthony, M.B., C.M., I.M.S.; Alexander W. Beveridge, M.B., Ch.B.Edin.; Frederic J. Brodie, M.D.Toronto; Robert Donaldson, M.B., Ch.B.Liverpool; Ethelbert W. Dyer, M.B., Ch.B.Edin.; Edward A. Elder, M.B., Ch.B.Edin.; Carlton A. Ellis, M.R.C.S.Eng.; Ernest G. French, M.D., R.A.M.C.; Samuel T. Irwin, M.B., M.Ch.Belfast; Harley P. Milligan, M.D.Edin.; Ronald R. Murray, M.B., Ch.B.Edin.; Herbert C. Orrin, L.R.C.S.Edin.; John A. Pottinger, M.B., Ch.B.; Eliyatamby V. Ratnam, L.R.C.S.E.; Harold E. Rawlence, M.B., M.R.C.S.Eng.; Alexander M. Westwater, L.R.C.S.E.

## NOTICES TO CORRESPONDENTS, &c.

**NOTES.** CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

### SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs 15.12. Messrs. Dawson and Sons are our special agents for Canada.

### ADVERTISEMENTS.

FOR ONE INSERTION:—Whole Page, £5; Half Page, £3 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 15 insertions, at £3 10s.; 26 at £3 3s.; 53 insertions at £3, and pro rata for smaller spaces.

Small announcements of Practices, Assistances, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

ORIGINAL ARTICLES OR LETTERS intended for publication should be written on one side of the paper only and must be authenticated with the name and address of the writer, not necessarily for publication but as evidence of identity.

CONTRIBUTORS are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland to the Dublin office, in order to save time in reforwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

Mr. W. E. R. should address his protest to the Secretary of the British Medical Association. It is a matter over which we have no concern or control.

SCHOOL MEDICAL OFFICER.—A good paper on the subject of the "Control of Diphtheria in Schools" was read by Dr. T. Orr at the recent Congress of Medical Officers of Health at Leeds. He classified carriers under three heads:—(1) Those having diphtheria bacilli in their throats without showing, and without having shown, signs of the disease; (2) those suffering from a mild and unrecognised attack of diphtheria; (3) those recovering from this attack, recognised or unrecognised.

### A CONSIDERATE LUNATIC.

Not long ago a well-dressed man called on a medical man in the Rue de la Chapelle, and was ushered in by the servant. When the doctor entered the salon he was very much surprised to find his patient, completely undressed, sitting in the middle of the room, smoking a cigar.

"I did not wish to make you waste your time," said the visitor. "I'm afflicted with a skin affection, and so I undressed at once. Just order a vinegar bath for me."

The doctor sent for a couple of policemen, and the strange individual was assisted into his clothes, and taken off to the nearest police station. He was found to be a domestic, who was suffering from mental derangement.—*Globe*

DR. J. JOHNSON.—The question was raised editorially in our last week's issue, and is referred to in the correspondence column of our present number.

DR. H. S. W. is thanked for his communication, which we highly appreciate.

DR. J. E. B.—"All's well that ends well." In the present case there will be no action at law, and we are glad to know that expectant lawyers will not have the opportunity of "dividing the spoil."

## Appointments.

BEDD, ARTHUR, M.B., B.S.Durh., Medical Officer of Health of Launceston (Cornwall).

BUNTON, DUDLEY W., M.D., B.S.Lond., M.R.C.P.Lond., Lecturer to the newly created Lectureship in Anaesthetics at the Royal Dental Hospital of London.

CEALMERS, T. A., L.R.C.P. and S.Edin., L.F.P.S.Glasg., Certifying Surgeon under the Factory and Workshop Act for the Harris District of the county of Inverness.

DAILY, J. F. HALLS, M.D.Cantab., M.R.C.P.Lond., Physician to the St. Marylebone General Dispensary, Welbeck Street, W.

FLINT, H. L., M.B., Ch.B.Leds, House Physician at the General Infirmary, Leeds.

HACKNEY, C., L.R.C.P.Lond., M.R.C.S., Certifying Surgeon under the Factory and Workshop Act for the Hythe District of the county of Kent.

HUNT, ERNEST, L.R.C.P.Lond., M.R.C.S., Medical Officer for the Kingsteigton District by the Newton Abbot (Devon) Board of Guardians.

KEYSER, CHARLES R., F.R.C.S.Eng., Surgeon to the Cancer Hospital, London.

MACK, E. G., M.B., B.S.Lond., House Surgeon at University College Hospital.

OLDFIELD, CARLTON, M.D., B.S., M.R.C.P.Lond., Honorary Surgeon to the Hospital for Women and Children, Leeds.

SAVAGE, WILLIAM GEORGE, B.Sc., M.D.Lond., L.R.C.P., M.R.C.S., D.P.H., Medical Officer of Health for the County of Somerset, and Medical Officer of Schools to the Somersetshire County Council.

SINCLAIR, HAROLD WEIGHTMAN, M.D.Lond., L.R.C.P.Lond., M.R.C.S., D.P.H.Lond., School Medical Inspector by the Gloucestershire Education Committee.

SPEARMAN, R., M.B., B.C.Cantab., Certifying Surgeon under the Factory and Workshop Act for the Clacton-on-Sea District of the county of Essex.

THOMSON, H. A., M.D., F.R.C.S.Edin., Professor of Surgery in the University of Edinburgh.

WALTERS, CHARLES FERRIER, F.R.C.S.Eng., L.R.C.P.Lond., Honorary Assistant Surgeon to the Bristol Royal Infirmary.

## Vacancies.

British Ophthalmic Hospital at Jerusalem.—Assistant Ophthalmic Surgeon. Salary £300, with house. Applications to the Honorary Secretary, British Ophthalmic Hospital, St. John's Gate, Clerkenwell, E.C.

Victoria Hospital, Burnley.—Resident Medical Officer. Salary £100 per annum, with residence, board, and washing. Applications to F. A. Hargreaves, Hon. Secretary, 7, Grimshaw Street, Burnley.

Parish of St. Leonard, Shoreditch.—Second Assistant Medical Officer. Salary £100 per annum, with rations, washing, and furnished apartments in the Infirmary. Applications to Robert Clay, Clerk to the Guardians, Clerk's Office, 213, Kingsland Road, N.E.

Salford Union.—Senior Assistant Resident Medical Officer. Salary £150 per annum, with furnished apartments and attendance. Applications to F. Townson, Clerk to the Guardians, Union Offices, Eccles New Road, Salford.

The Middlesex Hospital, W.—Lady Superintendent. Salary £150 per annum, with board and residence. Applications to F. Clare Melhado, Secretary-Superintendent.

St. Mary's Hospital for Women and Children, Plaistow, E.—Senior Resident Medical Officer. Salary £100 per annum, all found. Applications to Percy J. Glenton, Secretary.

Wigan Infirmary.—Junior House Surgeon. Salary £100 per annum, with rations and apartments. Applications to Will Taberner, Gen. Supt. and Secy.

Dorset County Hospital, Dorchester.—House Surgeon. Salary £100 per annum. Applications to W. E. Groves, Valetta, Icenway, Dorchester.

Leeds Union.—Assistant Medical Officer. Salary £120 per annum, with board, washing, apartments, and attendance. Applications to the Medical Superintendent at the Union Infirmary, Beckett Street, Leeds.

Royal Lancaster Infirmary.—House Surgeon. Salary £100 per annum, with residence, board, attendance, and washing. Applications to the Secretary.

The Children's Infirmary, Carshalton, Surrey (under the Metropolitan Asylums Board).—Assistant Medical Officer. Salary £150 per annum, with board, lodging, and washing. Applications to the Clerk to the Board, Embankment, London, E.C.

## Births.

BOKENHAM.—On July 26th, at Highview, Wokingham, Berks, the wife of Thomas Brandon Bokenham, Esq., M.R.C.S., L.R.C.P., L.S.A., of a daughter.

MILLIGAN.—On July 26th, at 11, Upper Brook Street, London, W., the wife of W. Anstruther Milligan, M.D., of a son.

NATHAN.—On July 28th, at 50, Harrington Gardens, London, the wife of Sidney Nathan, M.D., of a son.

ROST.—On July 27th, at Rangoon, the wife of Major E. Rost, I.M.S. (*née* Profumo), of a son.

## Marriages.

CECIL.—PORTEOUS.—On July 28th, at St. Katharine's Church, Southbourne, Charles Cecil, youngest son of the late Henry Cecil, of Bournemouth, to Marjorie Porteous, only daughter of the late Robert Burnet Porteous, M.D., of Dumfries.

CHAPLIN.—DOUGAL.—On July 29th, at St. Columba's, Pont Street, London, Arnold Chaplin, M.D., F.R.C.P., 3, York Gate, London, and 41, Finsbury Square, London, to Margaret Douie, widow of William Dougal, and eldest daughter of the late J. H. Robertson, J.P., M.D., of Singapore and Edinburgh.

CRABTREE.—BERRIDGE.—On July 29th, at St. Matthew's Church, Redhill, Frederick Lane Crabtree, of Sunningdale, Berks, son of the late Rev. E. W. Crabtree, of Darlington, Yorks, to Helen, elder daughter of William Alfred Berridge, M.R.C.S., of Oakfield, Redhill.

## Deaths.

BISHOP.—On July 27th, Augusta, widow of Captain T. Bishop, of Waylands, Uxbridge, and late of Bay View, Shanklin, I. of W.

CALDERON.—On July 26th, at Alsager, Stoke-on-Trent, Kathleen, the dearly loved wife of Commander John J. W. Calderon, R.I.M., and daughter of A. L. Haynes, M.D., Evesham, aged 28 years.

FRANCIS.—On July 29th, at Teddington, Emily, widow of the late Thomas Francis, M.R.C.S., L.R.C.P., of Acton, Middlesex, aged 90 years.

HOWAT.—On July 28th, at 8, Devonshire Terrace, Ventnor, I. of W., George Rutland Howat, B.A., M.D., in the 62nd year of his age.

PHILLIPS.—On July 27th, at Savoy Mansions, London, W.C., Alfred Phillips, M.R.C.S., aged 68.

SECCOMBE.—On July 28th, suddenly, of heart failure, at Luesdon, South Devon, Edward Hepburn Seccombe, M.B.Lond., of Belgrave Road, London.

## NOTES AND COMMENTS.

### A Membership for Scotch Diplomates.

As pointed out in previous issues, the question of a membership diploma is one of considerable importance to Scotch diplomates. Is there any substantial reason why a request of apparently so reasonable and moderate nature should not be granted? According to Dr. F. C. McWalter, the Council of the Glasgow Faculty of Physicians and Surgeons have recommended that their cumbersome—it might almost be said their grotesque—title should be altered to that of "Royal College of Physicians and Surgeons." That proposal was defeated by the Fellows in whom, for some inscrutable reason, the government of the College has been vested. Why should not the licentiates of the Colleges of Edinburgh and Glasgow, who are in the vast majority, be permitted to have a voice in their own affairs? It is their money that has fed the Colleges, and now that the irresponsible governing bodies are asked to extend to their diplomates a favour which will not only cost nothing, but will actually bring, if desired, large additional revenues to the College, they refuse, and give no reason for their refusal. The incident shows, at any rate, that the interests of the licentiates and those of the Councils are not identical, and that the Councils are not disposed to bestir themselves on behalf of the men whose fees they have accepted. When these facts are more fully realised, together with the disadvantages of starting practice on a licentiateship qualification, we may expect a falling-off to the point of zero of applicants for the qualification of the Scotch Colleges.

### What will Happen Then?

THEN, possibly, when too late, the Scotch Colleges will realise how comparatively easy it is to kill the goose that lays the golden eggs. For many a year there has been an exodus of students to Scotland, whither they have been attracted by the soundness of the teaching, and in some instances by a somewhat lessened standard of examination. In justice to the Colleges, it should be said that their examinations have been for many years past of a thoroughly sound and searching nature. It is just as easy now for any man of average abilities and industry to take an English diploma or the degree of a local English University. Why, then, should he journey afar to another part of the kingdom, where he has to work just as hard and as long, and where he pays just as much money, but gets in return an inferior article in the shape of a Licentiateship? The whole thing, when reduced to any sort of analysis, shrinks into the proportions of a full-blown absurdity. From more points of view than one, we think the Edin-

burgh Colleges will do well to be wise in time and to make a bid for some return of their waning popularity by reconsidering their determination to retain at all costs their time-worn traditional titles. According to Dr. A. G. Bateman's letter in our issue of August 4th, the Council of the Edinburgh College of Surgeons is specifically empowered to confer the title of Fellow and Member, with apparently not the least mention of the licentiateship. What has the R.C.S.Ed. to say to that?

### Paid Hospital Work.

HOWEVER anomalous it may be for the visiting staffs of hospitals to be unpaid, the old tradition of honorary service is likely to remain unbroken so long as selected medical men alone serve on the staff. The *kudos* of a hospital appointment is such, that as long as there are medical men with private means who can afford to wait for practice, or those of great ability or energy who can gain a livelihood in other ways, there will be no dearth of candidates. In this matter, as in every other commercial transaction, the question is one of supply and demand, and hospital boards are not likely to offer salaries out of their precarious incomes when they can get the work efficiently done for nothing. We wonder sometimes what difference the payment of hospital staffs would actually make in practice. No doubt the competition for posts would be even keener than it is now, but with this extra competition, qualification upon qualification would be piled up, the term of waiting for a vacancy would be by no means reduced, and the man without private resources, either earned or unearned, would be worn down in that waiting at least as much as he is at present. So that the probabilities are that unless with the salary attached to the post there went some corresponding payment for the junior posts, the individual composition of the staff would probably be little affected.

### Barry Docks Hospital.

THE point has been raised rather acutely at Barry, where hitherto the Town Accident and Surgical Hospital has enjoyed the services of an honorary staff. Lately, questions of administration arose in connection with practitioners whose private patients were treated there, and various proposals were made to meet the circumstances. The matter was taken up by the British Medical Association which has now submitted a scheme to the hospital committee, suggesting some interesting changes. It is proposed that every member of the profession in the town of six months' standing, should be allowed to act on the staff in rotation, and that a payment of a fixed honorarium should be made to each member, £20 for a three months' term being suggested. The

committee expresses some surprise that payment should be looked for, but it was explained to them that it would cease to be a distinction to serve on the staff, and that, therefore, the market rate of wage would be looked for as compensation. We are unwilling to criticise a scheme which may, for aught we know, be suited to some peculiar circumstances of the locality, especially as it has received the unanimous endorsement of the Cardiff Division, but we may say *en passant* that we can imagine very few districts, of an urban nature, in which any such plan would work harmoniously for any length of time.

#### Dentists and Anæsthetics.

THE question whether qualified and registered dental surgeons should be authorised to administer anæsthetics, or, at least, nitrous oxide, was answered in various voices before the Departmental Committee on Coroners' inquests, the interim report of which has been already issued. Dr. Hewitt expressed his conviction that in dental operations the same man should not administer the anæsthetic and perform the operation, and contended that it was not desirable that qualified dentists should administer even "gas." It was his belief that a Bill prohibiting dentists from using anæsthetics would raise the status of the profession and help to stop quack practice. Dr. Dudley Buxton disagreed in several respects with the evidence offered by Dr. Hewitt. He considered that it would be a hardship on registered dentists and a great inconvenience to the public if they were not allowed to administer gas. He also thought that the prohibition would lead to their employing other agents, such as cocaine, which would be probably more dangerous. Mr. Leonard Matheson, ex-president of the British Dental Association, agreed with the evidence of Dr. Dudley Buxton, and they both supported Dr. Hewitt in condemning the practice of administration of an anæsthetic by the same man who was to perform the operation. There certainly seems much to be said in support of the view of Dr. Dudley Buxton, and this view was forcibly put forth in our correspondent columns recently by a leading dentist, an ex-president of the Odontological Society. A properly qualified dentist is a professional man whose education has included study of general medicine and surgery sufficient to enable him easily to master the art of simple anæsthesia, as represented, at any rate, in the use of nitrous oxide for tooth extraction. To sanction the employment of anæsthetics by this class—men imbued with professional responsibility—is a different thing from conferring the same privilege upon unqualified practitioners.

#### A Cool Request.

THIS privilege was asked for before the Committee by a gentleman who represented himself to be Secretary of the Incorporated Society of Extractors and Adaptors of Artificial Teeth. If such sanction were afforded by the legislature, there would be no possibility of restricting unqualified practice in any department. It would be made impossible for the public to distinguish between unqualified and qualified practitioners, and the beneficial effects of the Dentists' Act in this direction, now becoming so visible, would be at once put an end to. It is not likely that the legislature will seriously consider such an innovation. Men who elect to practice without legal qualifications must do it at their own risk. The object of the law must be merely to make it as certain as possible that the simple public shall not mistake men who can give no guarantee

whatever of competence for those who have been properly educated, and have proved their capacity by examination.

## LEADING ARTICLES.

### THE ROLE OF SPECIAL HOSPITALS.

THE claim of a correspondent in the *Times* that the proposed scheme of the governors of the Heart Hospital, in Soho, to erect a new institution at a cost of £35,000 is "without justification," raises again the question of the rôle of special hospitals. It is essential at the outset to take a broad-minded view of this matter. There is, for example, too much tendency in the present day to forget the great services to the profession, and even to the State, which the special hospitals have accomplished in the past. One of the first of these details to which attention may be especially directed is that they have proved to the large general hospitals the necessity of establishing special departments as part of their organisation. Not only have the special hospitals shown the necessity of these special departments, but they have also provided the details for construction and equipment of the same, by which it has been possible to ensure that the usefulness for teaching purposes of these departments can be relied upon. Moreover, no one can possibly deny the great position which these special hospitals occupy as teaching centres themselves, not so much perhaps to the general student, but to those who, having determined their speciality, seek to gain their knowledge of it by studying at the hospitals concerned. And there is no exception to this rule. All special hospitals must, perforce, fulfil this rôle for teaching purposes. They naturally become centres of instruction, with which the special departments at the general hospitals can in no way compete. For the most part the latter are officered by certain members of the staff who are either engaged in general medicine or surgery, or whose special hospital practice is confined to the special department over which they preside; that is to say, many of them are not specialists in the strict sense of the term, and it not infrequently happens that as soon as their work in other directions advances in magnitude, they signalise their claim to be specialists by resigning their special appointments. All these points arise from a general consideration of the subject. We will now descend to the particular, and proceed to inquire whether, in our opinion, the "without justification" claim, in regard to the Heart Hospital, is rightly based, having regard to the circumstances of the case. In the first place, reference may be made to the fact that the two great hospital funds have initiated a scheme compelling the amalgamation of certain special hospitals. This policy may be—possibly is—a right one from an economic point of view in the case of hospitals engaged in the same class of work. On the other hand, however, this scheme of amalgamation cannot be made to apply to the Heart Hospital, inasmuch as it is the only one of its kind in the metropolis. As, therefore, this is the case, and as the pet scheme of amalgamation is inapplicable to it, and mainly, too, because the institution is a small one, the governors and

the public have been told through the *Times* that its work is unneeded, and its claim for support "without justification," on the grounds that there are many empty beds in the medical wards of the general hospitals, to which its patients should be referred. No one who is prepared to concede the important rôle played by the special hospitals in the education of the profession, could possibly admit the soundness of this argument. If it be granted that there is specialism in heart diseases, and "heart specialist" is a title recognised in the profession, a hospital for diseases of the heart, where the speciality can be practised and advanced, seems only to be in accord with the natural fitness of things. In a very mild letter to the *Times*, the secretary of the Institution replies to the attack made upon the governors, in doing which we think that he has omitted to state many points to which public attention should have been directed. Meanwhile, we commend to the governors of the hospital the position in which they stand, in our opinion, from the professional point of view, and we doubt not, if the matter were to be placed clearly before the charitable public that no great difficulty would be experienced in raising the sum for which they propose to appeal.

#### MEDICAL CHARITIES AND COMPENSATION CASES.

THE complex nature of our modern social system is nowhere better illustrated than in the various extramural relations of the voluntary medical charities. For generations past the voice of the general practitioner has been raised against the evils of hospital competition. A week ago it was raised with no uncertain sound against the discharge by the medical charities of the duty of attending school children. It is clear that if the hospitals attend these patients gratuitously they are taking upon their shoulders the burden that belongs to the State, and that should be referred to the medical profession and paid for by the State. It is somewhat surprising that any responsible public hospital should be willing to enter into any agreement with the local education authorities for the treatment of defective school children, gratuitously or otherwise, in view of the emphatic disapproval of the medical profession. Yet one of the largest London hospitals has agreed to provide for that class of patients without payment. Should medical men ever reach the stage of an effective fighting force the day of reckoning will come for institutions that have for so long a time treated outside medical men with contemptuous indifference. Another point in which the medical charities have recently come into competition with medical practitioners is in the administration of the Workmen's Compensation Act. Any poor person injured in the course of his employment, be the injury trivial or serious, goes off to a hospital for treatment in nine cases out of ten. Equally as a matter of course the patient applies for a certificate in order to apply for compensation. The certificate is furnished without fee, and signed by members of the honorary staff. As an outcome of the transaction the hospital suffers, the honorary member of the medical staff is drawn into gratuitous work for which he is not responsible, while the workman secures an important legal document whereby

he obtains a substantial sum of money, not a single penny of which goes to the benefit of the profession whose services are essential at every stage of the transaction from start to finish. Well may the general practitioner throw up his hands in despair and declare that his days are numbered in the land! One discouraging aspect of the affair is the difficulty of making persons outside the medical profession understand that there is anything economically unsound or unjust in the granting of certificates by hospital authorities for use in compensation cases. A few weeks since, in Sheffield, a County Court judge declaimed against the system of hospital certificates, not on the ground of their injustice, but because they were supplied to employers, and he suggested with an indefensible want of manners that hospital officials acted as spies upon patients, and supplied employers with information inimical to compensation claims. Judge Dodd may be comforted by the reflection that the "spies" are, at any rate, unpaid. We doubt if there is often laid before him any sort of evidence so clean, so clear, so unbiassed, and so relatively accurate as the medical certificates based upon the hospital notes, which constitute the documents that excited his ire. The objection that the majority of medical practitioners have to the certificates does not arise on the score of accuracy or of good faith, but from the prosaic fact that their gratuitous issue deprives a hardly-worked and poorly-paid profession of its just due. Let Judge Dodd inquire how many documents come into his Court that have been given without charge by lawyers to poor clients. As regards disputed claims, we have always maintained that conflicting medical evidence in law courts lowers the profession in the eyes of the lay public. We have urged on various occasions the desirability of some machinery whereby any unseemly wrangle could be avoided. All such cases might be investigated by three referees appointed by the Court, and the facts for and against could be stated by them without fear or favour. Meanwhile, as regards the practical issue of the gravity of hospital reports in compensation cases, it is to be hoped that an authoritative opinion will be issued by the medical profession for the guidance of those institutions whose boards of management do not wish utterly to disregard the legitimate interests of the rank and file of the medical profession.

#### CURRENT TOPICS.

##### Ophthalmia Neonatorum.

A CORRESPONDENT has reminded us of an editorial article published in THE MEDICAL PRESS AND CIRCULAR of April 1st, 1908, in which the use of the term "ophthalmia" is adversely criticised, and the substitution of "conjunctivitis" advocated. It was by no means our intention to turn an old friend like "ophthalmia" out into the wilderness of oblivion. The wish of all scientific men, of course, is naturally to aim at the use of words that are more and more accurate and informing, that is, words which denote and connote more than their predecessors. For all that, a good general term has its value in terminology, and when qualified by one or more limiting adjectives, it is often most convenient and adaptable for descriptive purposes. The word "ophthalmia" is sanctioned by usage, and it will need more than a few fleeting journal paragraphs to root it out of our text-books. Few medical men would be at a loss, moreover, to understand what is meant by such terms as granular ophthalmia, or ophthalmia neonatorum.

It is true of the latter condition that only a majority of the cases are due to the specific pathogenic agency of the gonococcus. To call the affection conjunctivitis neonatorum is, therefore, to travel little more in the direction of accurate definition than if we adhered to the old term. To secure more absolute accuracy we should have in all cases to tack on the name of the actual causative micro-organism. There would then be little to choose between gonococcal ophthalmia neonatorum and gonococcal conjunctivitis neonatorum. Ophthalmia, again, is a convenient general term descriptive of a whole series of secondary and more or less remote changes which would not be embraced by conjunctivitis. Upon the whole, most medical men will probably think the matter is about as broad as it is long. It is a point that in the days of the ancient school men might have raised a strife of gargantuan dimensions, but nowadays is likely to be permitted to settle itself amid the rush and hurry of progressive modern science. There is even a remote chance that our old friend ophthalmia may one day follow the example of so many words of ancient lineage, and take unto itself a secondary meaning. In any case, we are obliged to our correspondent for pointing out our own inconsistency in adhering to the old order of things, after so vigorously dwelling upon the quite respectable virtues of the new.

#### The Economic Aspect of Acute Appendicitis.

THERE is no doubt that some diseases have an utilitarian and economic aspect, and in none is this feature so noticeable as in acute appendicitis. The age is one of rush and hurry, one in which there is no time to be ill, no leisure to eat and be satisfied, no time to attend to anything beyond the urgent calls of professional and business cares. "You must pull up," says the doctor to an over-worked and harassed patient, "and take a holiday at once." "My good sir," is the reply, "I simply have not the time." And so, despising the warning, men either soon become physical wrecks, derelicts of the age, or pass from this life into a premature grave. Fortunately, however, for some, a sudden illness befalls them; in a few hours they find themselves lying on a bed from which they cannot move. A surgeon is summoned, and the verdict is acute appendicitis. Then follows an urgency operation, nowadays, when performed under favourable conditions, a safe and trustworthy procedure, one which necessarily compels a man to rest, one which affords him plenty to think about, without leaving much opportunity for worry concerning his professional and business affairs. Meanwhile, he is always resting, without being actually ill, after the first few days of relief having been obtained. In a month's time he is practically convalescent; his life has been doubly saved, saved by the operation, and saved by the enforced rest to which he has submitted. And in due time he is enabled to embark upon a new lease of life, of which added strength, both of mind and body, are features which he is the first to recognise and appreciate. Verily, as the experience of operating surgeons has frequently shown, an attack of appendicitis has proved "a blessing in disguise" to many an over-worked man in the present "high speed" age.

#### Ambulance Service for London.

AFTER long years of waiting, the agitation in favour of a street ambulance service for London has reached the stage at which a Bill to establish such

a service has been presented to Parliament. The measure is to be brought in by Mr. Peel, a member of the London County Council, who, curiously enough, wishes to make the Metropolitan Asylums Board the authority of its administration. It will be remembered the Home Office Committee, which recently inquired into the question, recommended the same authority, Sir William Collins, in a minority of one to two, advocating the County Council. For reasons we have already given, we think it is clear that the County Council should be the authority, if the police are not to be, and we are sure a much more efficient service would be given by them. But we earnestly trust that the measure will not be hung up on this point. An ambulance service is a crying necessity, and has been so for years; the number of street accidents is growing every day with the advent of more and more motors on the streets, and the amount of unnecessary suffering is immense. The whole Bill could be run through its three stages in ten minutes if taken as an unopposed measure, and we cannot believe that those who really have the interests of London at heart will see this reform kept back on a point which, after all, is of minor importance.

#### Progress in Obstetrics.

THE Address in Obstetrics, delivered before the British Medical Association by Sir John Byers, was an admirable summary of the progress in the obstetric art since the last Belfast meeting of the Association, twenty-five years ago. The principal point of progress has been as regards sepsis. Whether judged by mortality or by some standard of morbidity, the improvement is enormous. In 1882, Macan, as Master of the Rotunda, reported the hospital as "particularly healthy." Yet in that year nine patients out of 1,109 had died, while over 25 per cent. were "morbid," as judged by modern standards. In 1907, out of twice as many patients seven died—three only of infection—while only 3.64 per cent. were morbid. Other maternities show a similar contrast. Again, in the country generally there has been a similar decline in the mortality. In England and Wales, in 1884, 186 women per million living died of puerperal sepsis; in 1907 only 81 per million. In Ireland, in 1884, the septic death-rate per 1,000 births was 2.57; in 1907 it was 1.60. It is interesting to note, too, how in the last few years the progress is as marked as at any previous part of the period under review. Sir John Byers is able to show, also, by what steps puerperal sepsis is avoided—cleanliness, restraint from interference, and immediate attention to lacerations. We regret we cannot follow Sir John through the whole of his encouraging address. He has a message for the present, as well as lessons from the past, and we think him right in believing that the treatment of puerperal sepsis lies in the future in the hands of the vaccinists, rather than of the surgeons.

#### "Vicarious Philanthropists"

MUCH has been said in the last year or two in medical circles of the "vicarious philanthropist," who is so ready to exploit the medical man for the good of the community. We are glad to see that a very sensible clergyman, the Rev. H. D. Murphy, of St. George's Church, Belfast, took the opportunity of the recent meeting of the British Medical Association to utter some home truths on this subject to his parishioners. He chose as his text a too little-known passage from the Apocrypha:—"Honour a physician with the honour due unto him, for of the Most High cometh healing, and he shall receive honour of the King."

The skill of the physician shall lift up his head, and in the sight of great men he shall be in admiration. There is a time when in their hands there is great success." This is so excellent, we can only regret it is not in the canonical Scripture. Starting from this text, Mr. Murphy spoke seriously and eloquently of the shameful dishonesty with which medical men are often treated by those in their debt for life itself. We know no more fitting sermon with which to anticipate a meeting such as that at Belfast.

## PERSONAL.

MR. SYDNEY SCOTT, M.S., has been appointed Surgeon for Diseases of the Throat and Ear at the National Hospital for the Paralysed and Epileptic, Queen Square.

DR. DUDLEY BUXTON has been appointed to the recently created post of Lecturer in Anæsthetics at the Royal Dental Hospital, London.

THE Royal Boscombe Hospital, Bournemouth, has received an anonymous gift of £4,000 to defray the cost of erecting a ward for children.

AT Swansea Assizes Dr. Howell Thomas Evans, of Monmouth, claimed damages from the Great Western Railway for personal injuries, and was awarded £3,500 damages and costs.

WE regret to announce the death of Dr. Gustav Christ-Lott, Senior Physician to the Gynæcological Department of the Polyclinic at Vienna, and Professor of Gynæcology in the University.

A HANDSOME monument has been erected in the cemetery of Chard, Somerset, over the grave of the late Dr. Benjamin Powne, by members of the friendly societies of Chard and district.

LORD SANDHURST, Treasurer of St. Bartholomew's Hospital, has received from the Worshipful Company of Skinners the sum of £200, being the first instalment of a grant of £1,000 towards the capital fund of the hospital.

DR. EMRYS-JONES has been appointed by the Home Secretary to act for a further term of five years as medical referee in all ophthalmic cases for county court circuits No. 5, 7, and 8, which comprise most of the large towns in Lancashire and Cheshire.

DR. WILLIAM SAVAGE has been appointed Medical Officer of Health and Chief Medical Inspector of Schools for the County of Somerset, in succession to Dr. Stevenson, appointed Superintendent of Statistics at Somerset House.

DR. W. BEVAN LEWIS, Medical Superintendent and Director of the West Riding Asylum, Professor of Mental Diseases in Leeds University, has been elected President of the Medico-Psychological Association of Great Britain and Ireland.

AT a recent meeting of the Managing Committee of Jervis-Street Hospital, Patrick T. McArdle, M.B., B.Ch., B.A.O., R.U.I., Assistant Master to the National Maternity Hospital, Holles Street, Dublin, was appointed Gynæcologist to the hospital.

MISS IVY E. WOODWARD, M.D.Lond., having passed the required examinations, was admitted, at the last comitia of the Council of the College, a member of the Royal College of Physicians of London. Miss Woodward is thus the first female student admitted to the membership of the College.

THE Vice-Chancellor of London University, Professor M. H. M. Hill, has appointed Dr. A. D. Waller, M.D., LL.D., F.R.S., Director of the Physiological

Laboratory, to represent the University at the inauguration of Dr. A. L. Lowell as President of Harvard College on October 6th and 7th.

PROFESSOR HARVEY CUSHING, M.D., of the Johns Hopkins University (U.S.A.), delivered the fifth William Mitchell Banks Memorial Lecture on Wednesday last, in the surgical theatre of the Medical School of the University. The subject of the Lecture was "Recent Observations on the Pathology and Surgical Treatment of Intra-cranial Tumour." There was a large gathering of medical men and students.

THE most interesting episode in connection with the meeting of the British Medical Association was the admission of the Countess of Aberdeen to the membership of the Association. No higher honour is it in the power of the Association to bestow, and under the circumstances the tribute to the work which her Excellency has accomplished in the anti-tuberculosis campaign inaugurated by her in Ireland is unique.

DR. BREINL, of the Liverpool School of Tropical Medicine, formerly assistant to Professor Chiara, Prague, has been nominated to the directorship of the newly-founded School of Tropical Medicine in Western Australia. He is chiefly known for his researches regarding sleeping sickness. Dr. Breinl joined the Liverpool School of Tropical Medicine in 1904, and was appointed shortly afterwards to proceed to Manaoas on the School's Yellow Fever Expedition.

MR. ERNEST FREDERICK SCHIFF, of Carlos Place and Warnford Court, has presented, through Mr. Mayo Robson, to the managing committee of the Home of Recovery, of which H.R.H. Princess Louise is president, the sum of £100,000. This announcement was made public on the anniversary of the death of Mr. Alfred George Schiff, the brother of the donor, in whose memory the gift has been made. The Institution will be called "The Schiff Home of Recovery."

A REPORT by Professor Karl Pearson was presented at a meeting of the Senate of London University, which shows the progress of the work of the Francis Galton Laboratory for National Eugenics during the past 16 months. The Senate have voted thanks to Sir Francis Galton for a further donation of £500 for the maintenance of the laboratory, and recorded their high appreciation of the services rendered by Professor Pearson. Mr. David Heron and Miss E. M. Elderton have been reappointed respectively Galton Research Fellow and Galton Research Scholar for a year from next February.

AT a meeting of the Curators of Patronage of the University of Edinburgh, on July 29th, Lord Provost Gibson presiding, the vacancy in the Professorship of Anatomy was filled by the appointment of Professor Arthur Robinson, M.D., C.M., Professor of the same subject at Birmingham University.

THE new Professor is a graduate in Medicine of the University of Edinburgh, where he obtained the degrees of Bachelor of Medicine and Master in Surgery in 1883, graduating with honours. In 1890 he proceeded to the higher degree of Doctor of Medicine, and was awarded a University gold medal.

IN 1896 Professor Robinson was appointed lecturer on Anatomy in the Middlesex Hospital Medical School. Whilst holding that appointment he entirely reorganised the Anatomical Department, supervised the erection of new buildings for its accommodation, and placed it, as regards adaptability to, and efficiency for, its purpose, in a position second to no other Anatomical Department in London. In December, 1900, Professor Robinson was appointed Professor of Anatomy in King's College, London. In December, 1904, he was elected to the chair of Anatomy in the University of Birmingham, and in 1905 was appointed Sub-Dean of the Medical Faculty. In the summer of 1903 he was appointed Hunterian Professor by the Council of the Royal College of Surgeons of England.

# A CLINICAL LECTURE

ON

## ADENOIDS: SOME CAUSES FOR THEIR ENLARGEMENT AND REASONS FOR THEIR REMOVAL.

By HORACE LAW, M.D., F.R.C.S.,

Surgeon to the Throat Department, Adelaide Hospital, Dublin; Consulting Throat and Ear Surgeon to the Stewart Institution.

PROBABLY the two most common questions propounded by the anxious parent of a child after a verdict of "adenoids" has been given are: "Doctor, what causes them?" (adenoids), and "Why is it necessary to remove them?" I propose to attempt in this lecture to give an answer, which, if lacking in completeness, at any rate, sums up the position fairly.

In the first place, let us try to discern why, in these days of scientific knowledge, the growth of adenoid vegetation in the naso-pharynx should be far commoner than in the days of our fathers, for, in spite of the fact that in days gone by the presence of adenoids was not suspected, we can hardly gainsay the fact that if they had been as prevalent then as they are now, they would not have remained undiscovered. The conclusion, then, is that they are indeed more common now than formerly. Had the answer to the above question to be given in one word, I should say, "civilisation." In what way does our present mode of life differ from that of our forefathers? Mainly in the intensiveness with which everything is done, and the hurry and haste of life. While this is mainly true of adults, it reacts on child life also, and, beginning with the infant, we can enumerate some of the direct causes which can best be summed up in the statement, that anything which will produce congestion or stagnation of blood will tend to produce hypertrophy, coupled with chronic congestion, and all the causes to be mentioned appear to me to act in this way. I purposely omit here all references to deformities of nose, etc., as they obviously would produce congestion, etc.:-

1. The habit of many mothers of not feeding their own child by the breast. This contributes in two ways: the first, that the artificial food cannot be as good or as suitable as the natural milk, and, secondly, that the mechanical act of sucking is different with a long india-rubber teat from that at the breast. If the teat has too big a hole, the infant feeds too fast and has to be checked by allowing a partial vacuum to form in the bottle, or if the hole be too small the force necessary to extract the milk is too great; either way it is hardly likely to be right.

2. Following on the above, the great temptation to use a comforter—an abominable instrument, against the use of which nothing too strong can be said.

3. The next stage will be when white bread is given, from which the most necessary elements have been removed, and perhaps a good dose of alum added to make it white; the flour used for biscuits, rusks, etc., has the same drawbacks. A great deal has been said upon this subject which I need not enter into here.

4. Later on studies begin, and the anxious parent allows the child to be pressed on to compete with others; and truly, also, the child, eager to excel in competition, vies with its fellows, till exhaustion and congestion are added to an overstimulated nervous mechanism. Here I must add a word about school hours and feeding. This only

applies to day schools, and more especially girls' schools. The little one is given its breakfast at 8 a.m. to 8.30 a.m., as the case may be; a little packet of lunch, so-called, is made up, and off goes our fast-growing youngster to battle with its lessons from 9.30 onwards; a short interval is allowed about 12 for lunch, and then to work again till 1.30 or 2 perhaps. Then school hours are over, and our youngster starts for home, having attempted what should be a day's work in a few hours. The various distances to home means a dinner-hour as late as three in some cases, and the principal meal of the day is postponed until, over-tired, with hunger gone, our little friend cannot eat what is put before it. The above is absolutely accurate of some cases I have had under my care, or I would not have dared to write it down. The other causes to be enumerated apply over the whole range of child life.

5. Frequent infection with ordinary colds (acute rhinitis), by contact with others suffering from this disorder, owing to overcrowding, collection of children into crowds, as at school, &c.

6. The various infective fevers passed on in the same way as above-mentioned.

7. Bad air. This includes a variety of causes, from town life to escapes of coal gas. Naturally, the town dweller is at a serious disadvantage here, even if we allow for the fact that the country cottage is badly ventilated at night, as the door is the principal opening for ventilation, and is shut tightly when the family retires to rest.

8. A vitiated atmosphere, due to too many sleeping in the same room, or to gas burning without proper exit for the burnt products, or to a badly-drawing grate allowing smoke, etc., into the room, or to slight leaks in the gas connections, so small as to be unnoticed by smell, and, lastly and worst of all, sewer gas from bad drains. One could enlarge on the above, but enough has been said to indicate the direction in which we should look.

9. Adenoids certainly tend to run in families, but the actual cause may be one of those mentioned above, and not a genuine hereditary taint.

10. A damp room or house, or even the emanations from a damp basement or cellar under the house, seems to have a detrimental effect on the general health, and should be considered, at least, as an indirect cause.

The second of our main questions is concerned with the reason for operation to remove the growths, and it may be confidently stated that we do not remove adenoids merely because they are enlarged, but because of their various sequelæ. These resulting changes and disorders may be divided into those which have their seat locally, and those affecting the general system. One or more may be present in any given case, though it is most usual to find several associated together in varying severity. The local manifestations are: deformities of the upper jaw and septum of the nose, hoarseness and involvement of the tonsillar tissue in the hypertrophy, and, finally, ear troubles, which consist in acute and chronic catarrh and

suppuration, with all their accompanying train of woes. There has been much discussion about the deformities of the upper jaw leading to a highly-arched palate and narrowed alveolar arch, with consequent overcrowding of the teeth and protrusion of the incisors. The bending-up of the hard palate naturally causes a shortening of the distance between the septal processes of the superior maxillæ and the hard bone of the frontal and body of sphenoid, and thus leaves too little room for the nasal septum, which, perforce, must bend or break to accommodate itself to the insufficient space. Thus the mechanism of the production of deviated and otherwise deformed septa is explained. How far all this should be laid to the door of enlarged adenoids is hard to say, but the fact remains that adenoids are usually present in these cases, and if they be removed early enough before the bones have become too firm and set, a considerable improvement in the development of the jaw may be expected, so that for practical purposes the removal of the mass of adenoids is to be confidently recommended. Chronic rhinitis with hypertrophy seems to be a later result, and rarely is present to any extent in children under eight years of age, but in direct proportion as the age advances the likelihood of hypertrophic changes being found in the nose increases, till, in cases where the adenoids have been suffered to remain to the age of from fourteen upwards, the probability is that steps will have to be taken to deal with this hypertrophy after the removal of the adenoids, if the case is to have a successful issue.

Hoarseness in children is not, as a rule, a result of adenoids, though it is sometimes noted in these cases. By far the larger number of cases of chronic persistent hoarseness that I have seen are not associated with adenoids, or, if the growth is present, its removal has no beneficial effect on the voice. By far the most serious complications are found in the ears; few children get acute or chronic catarrhal or suppurative otitis who have not enlarged adenoids, and how many cases of measles and scarlatina who have adenoids present escape without involvement of the ears?

Most, if not all, children suffering from adenoids show changes in the tympanic membranes, due to obstruction of the Eustachian tube, though these may not have caused noticeable deafness, or, at most, a little deafness with each cold. Nearly all these catarrhal cases do well after operation, though it often takes a long time before the drums regain their normal position and appearance. Every child suffering from chronic suppurative otitis media should be examined for adenoids. A case in my practice illustrates this very well. A fine healthy girl, æt. 6½, was brought to me with a discharge of pus from one ear; a little perforation was seen and a small quantity of adenoids found and removed. The ear dried up almost immediately, and three weeks after the operation the child got scarlatina, which was of a fairly severe type; notwithstanding this, no return of discharge from the ear was observed. No one can trace the possibilities of harm due to suppurative ear trouble, for not alone is the hearing power in question, but the very life of the patient may be placed in the gravest jeopardy.

Now, in dealing with the results to the general system of the presence of adenoids, we may mention general delay in development, and debility with liability to catch cold, often followed by more serious chest affections, to wit, bronchitis, tuberculosis, &c., maldevelopment of the chest walls, mental apathy and inattention to lessons, and such

reflex troubles as cough, enuresis, &c. Here, again, it will be right to mention that the mere size of the adenoids is not necessarily an index of the amount of the consequent damage, as often a small piece of adenoids, which has become inflamed and infected with micro-organisms of various kinds, sets up more trouble than a larger growth in a quiescent state; and, further, there are many cases which in the prone position allow of complete obstruction to nasal respiration, due to the congestion of the otherwise slightly hypertrophied adenoids, which, when examined by day in the upright posture show but little enlargement. In cases, brought because of some general as well as local manifestation, it is important to remember that a very small piece removed may effect a most excellent cure. The fact that there is not much to remove, while the troubles of our little patient are clear and unmistakable, is no bar to a brilliant result after operation, as the following cases show:—

1. A little girl, æt. 4½, who had suffered for two months from almost continuous bronchitis (she was hardly out of one attack till she began another), was seen by me in consultation, after all other means had failed. She breathed through her nose when asleep, but discharge of mucus from the nose and throat was noticed. I found a small quantity of adenoids and very easily removed them. This was done in the month of November, and she passed the subsequent winter with only one slight cold.

Two boys, brothers, æt. 11 and 10, got, without apparent cause, colds with high temperature at frequent intervals, so much so that their education was interfered with; again, they breathed through their noses fairly well. Removal of a moderate amount of adenoids completely stopped these feverish attacks.

The above three cases may be taken as representing cases where the mass of the adenoids contains infective material, which only awaits some insignificant cause to light up into fresh activity. In this category I could mention many cases of purulent discharge from ears, cured in a short time by the same operation. In cases where marked delay in development is found, usually the quantity of adenoids is much greater, and therefore the diagnosis easier; but a comparatively small increase in size, especially where congestion is superadded, causes much mental apathy, and leads to bad school reports and opportunities lost which can never be recovered. It is most interesting to get the school reports of a youngster after the operation, and nine times out of ten the reports, previous to treatment, speak of our little patient as bright and intelligent, but very inattentive, while the subsequent ones dilate on the marked improvement in attention and application. The other general conditions and reflexes speak for themselves, provided the possibility of adenoids as a cause is remembered.

Our subject does not permit of a discussion on the methods of operation, but I merely give, as my personal opinion, that I consider gas and ether the ideal anæsthetic, the recumbent position with the head over the end of the table the ideal position, and early removal after the signs of trouble are observed as the ideal time.

---

NOTE.—A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by Prof. Albert Hertz, M.D., University of Vienna. Subject: "Acute Leukæmia."

## ORIGINAL PAPERS.

## SOME INTERNAL DERANGEMENTS OF THE KNEE-JOINT. (a)

By ALBERT CARLESS, M.S.LOND., F.R.C.S.,

Professor of Surgery in King's College, and Surgeon to King's College Hospital; Examiner in Surgery to London University, &amp;c.

It is just over a century since William Hey, of Leeds, first published his description of this type of injury in his book, entitled "Practical Observations in Surgery, Illustrated by Cases," which appeared in 1803, and a second edition of which was issued in 1810. It was a subject that naturally interested him keenly, inasmuch as, at the age of 37, when he was in full practice, with many operations to undertake and much responsibility resting on him, he was for a while laid aside entirely from active work for some months by an injury to his knee, from which he never recovered fully. Five years later he received a blow on the thigh of the weak limb from a horse which disabled him so completely for a time that he was doubtful as to ever regaining the power of walking. After spending four months in London, Bath, and Harwich, seeking help and health, he returned to Leeds in splendid physical health, but hopelessly lame as to the knee, and from henceforth for the forty remaining years of his life he was unable to walk without a crutch except across a moderate-sized room, whilst to stand unaided for more than a few minutes was impossible. He could ride in the town for a short way on horseback, but usually he drove everywhere. No wonder, then, that all injuries to the knee attracted his keen and discriminating attention, and the extent of his practice gave him ample opportunity of seeing many such cases. In the paper included in his surgery he refers only to four patients, but mentions that others had been seen by him. In all the cases described, one of the semilunar cartilages had apparently been displaced for some time, and had remained "out," so that the power of locomotion had been seriously impaired. He treated the cases by flexing and extending the limb forcibly, and this usually brought about a restoration of the normal position of the cartilage. Hey himself does not seem to have appreciated exactly what happened in these lesions. His own description is as follows:—"The complaint which I have described may be brought on, I apprehend, by any such alteration in the state of the joint as will prevent the condyles from moving truly in the hollow formed by the semilunar cartilages and articular depressions of the tibia. An unequal tension of the lateral or cross ligaments of the joint, or some slight derangement of the semilunar cartilages, may probably be sufficient to bring on the complaint. When the disorder is the effect of contusion, it is most likely that the lateral ligament of one side of the joint may be rendered somewhat more rigid than usual, and hereby prevent that equable motion of the condyles of the os femoris which is necessary for walking with firmness."

Sir Astley Cooper, writing in 1831 in the fifth edition of his "Treatise on Fractures and Dislocations," speaks appreciatively of Hey's work, and mentions that he had sent cases up to Leeds to be treated by him. He describes the causation most accurately. "The injury," he says, "most frequently occurs when a person in walking strikes his toe with the foot everted against any projection (as the fold of a carpet), after which he immediately feels pain in the knee, which cannot be completely extended. I have seen this accident also happen from a person having suddenly turned in his bed, when, the clothes not suffering the foot readily to turn with the body, the thigh-bone has slipped from its semilunar cartilage. I have also known it occur from a sudden twist of the knee inwards when the foot was turned out." In contradistinction to Hey, Cooper attributed the lesion to laxity of the ligaments passing from the tibia to the cartilage. He also emphasised the fact that repeated displacement may produce what he calls chronic rheumatism, and describes a case in which the ana-

tomical conditions were identical with those which we now describe as characteristic of chronic traumatic arthritis.

From this time onward little progress was made in the recognition and accurate study of this condition until Listerian methods enabled us to open knee-joints safely and ascertain in the living subject what was the actual cause of the various derangements met with in practice; it is now obvious that many and various lesions may interfere with the equable movement of the joint, and that in several of them no hope can be entertained of improvement apart from operation. Increasing indulgence in athletic exercises of various types, such as tennis and football, particularly the Association game, makes the number of cases now coming under observation probably larger than ever before, and it is essential that a clear idea be obtained of the various possible causes of such derangements, and that the practitioner should be able to differentiate those which require operation from those in which other measures may be relied on.

For the clear comprehension of these cases it must ever be remembered that the anatomical arrangements of this joint are somewhat peculiar. No articulation in the body is more exposed to stress and strain from the combined influences of the weight of the trunk and the necessity for speedy and effective locomotion, whilst all sudden movements, such as jumping, twisting, etc., impose heavy calls upon the stability of this part. And no articulation in the body is less suitable to withstand such strains, from a *prima facie* view. The lower end of the femur is formed of two rounded bodies separated by a deep sulcus, except in front; the upper end of the tibia is practically convex from side to side, and these two awkwardly shaped surfaces have to be kept in apposition by ligaments. The convex end of the tibia is fitted to the lower extremity of the femur by the intervention of the semilunar cartilages, which not only form a shallow cup for the femoral condyles to rest in, but also constitute a buffer for the distribution and diminution of shock. Necessarily, the ligaments of the joint are of great strength, and peculiarly arranged so as to prevent rotation or lateral movements, which would be undesirable. The patella protects the front of the articulation, and by fitting closely between the femoral condyles in the inter-condyloid groove assist in giving stability from lateral and rotary strains. A certain amount of unoccupied space necessarily results from such a disposition of the parts, and this is filled in by fatty pads, which, however, occasionally become a source of trouble and inconvenience, and must be included amongst the possible sources of internal derangement.

One of the most troublesome affections of the knee, from the point of view of treatment, is what is known as a Simple Sprain, that is to say, a lesion due to rupture of some of the ligaments. These are of almost everyday occurrence, and the internal lateral ligament is naturally that which is most often involved. The fact that the upper ends of the femora are displaced outwards, in order to allow of the interposition of the pelvis between them, explains that in the erect posture there is always a certain element of strain upon the internal lateral ligament; and hence it is essential that when it is torn or injured extra care be taken in order to restore it to a state of functional perfection. An accident of this type is usually followed by a traumatic synovitis, in which there is an abundant blood-stained effusion, and the part becomes hot and painful. The patient is generally put to bed and the limb kept at rest. Perhaps an ice-bag is applied or a wet bandage, or, in some cases, fomentations are employed. It is a matter of comparative unimportance as to whether the practitioner relies on heat or cold, so long as the joint is kept at rest. Improvement follows within a comparatively short time, and then arises the difficult question as to when movement should be allowed, or the patient permitted to get up. Only too frequently the patient is allowed up too soon, and often the result is a repetition of the injury and a recurrence of the synovitis, whilst the spot of localised injury where the ligament is torn becomes very decidedly tender. On the other hand, cases are well-known in which the part is kept at rest too long, and adhesions form within the joint, which sometimes have not been recognised

(a) Paper read before the Ealing Branch of the British Medical Association, April 7th, 1909.

or treated until the patient has submitted himself to the tender mercies of the bone-setter.

It is, therefore, necessary to steer a clear and consistent course between these two possible dangers—too much rest, and too much movement. Be it remembered clearly, that rest by itself of an articulation never leads to immobility or stiffness, unless some abnormal pressure is exercised on the articular surfaces, or inflammatory troubles are present. When, however, a patient is permitted to walk about on an immobilised joint, or if there is some solution of continuity of the synovial lining membrane, then adhesions are only too likely to follow, and stiffness to result. Most of the troubles arise from non-recognition of the fact that whilst movement after a very short time does no harm to a joint, but rather does good, weight-carrying is harmful. In the treatment of a sprained knee, where there has been serious ligamentous lesion (and the same holds good after an operation in which ligaments have been divided), three stages must be included: firstly, absolute rest both from movement and weight-bearing; next, freedom of movement for the joint, but without weight-bearing; and finally, the patient is allowed to walk. The second stage is the important one that is only too often omitted. The patient should be allowed to move his leg in bed freely; massage is ordered, and the limb well worked, and subsequently, when this causes no pain, exercises against resistance are performed, whereby the ligaments are habituated to strain, which is regulated either by the use of a weight over a pulley, or by the educated muscles of the rubber. When at length the ligaments are obviously knit together firmly, the weight of the body can be well borne, and no harmful after-effects arise from the weight of the trunk being once more placed on the limb.

The most serious of all ligamentous lesions in the knee is Rupture of the Crucial Ligaments, fortunately a very rare occurrence, but one that has now been recognised in a few cases and dealt with effectively. Obviously they are torn more or less completely in all dislocations of the joint, but with care they may be repaired almost perfectly, although considerable trouble will need to be exercised in order to prevent any subsequent laxity on the one hand, or undue stiffness on the other. Movements with massage will be required for a considerable period of time, and the limb must be kept stiff in the intervals, probably for five or six weeks; then a support will be required, which will only allow of slight movement to begin with, but by the filing away of a stop, the range of movement can be gradually increased, and thus undue strain will not be placed on the ligaments too early.

Apart from complete dislocation, rupture of the crucial ligaments will be indicated by the existence of a to-and-fro antero-posterior movement of the tibia on the femur, or by free lateral mobility, perhaps of the rocking type, or by unnatural rotation. This is associated in the early stages with great pain and a sense of serious insecurity. If diagnosed early, treatment may be undertaken by opening the joint freely and stitching together the ligaments. This has been successfully accomplished in a few cases. It is quite a question whether much good would come of such a procedure in an old-standing case.

The true internal derangements that are likely to require operation are connected either with the semilunar cartilages, the articular cartilages, or the fatty pads, which, as already mentioned, fill up spare corners in the joint cavity. Of course, the semilunars preponderate enormously in the frequency with which injury occurs and operation is needed. Out of 25 operation cases which I have collected, the semilunars were affected in 22 instances, the articular cartilages in two, and the fatty fringes in one, and this about represents the proportion found in any series of cases.

In all the symptoms may be more or less alike, and it is only by the most careful investigation and scrutiny that a differential diagnosis can be reached, whilst in many cases this will be an impossibility apart from operation. The patient usually complains of a sense of weakness, and perhaps of pain. He feels insecure, and the joint not unfrequently gives way under stress. In some instances he merely complains of a recurrence of pain and swelling when he exposes

the joint to work or effort. There may be a tender spot, and the practitioner must investigate carefully as to the exact situation of the tenderness, whether on the joint line or above it. Crepitus may be obtainable, and the situation where it is produced, whether femoro-patellar or femoro-tibial, must, if possible, be ascertained. There may be difficulty in straightening the limb, or inability through pain to stand when it is straight. The most characteristic feature is a sudden painful locking of the joint, usually in a semi-flexed position, and the cessation of this fixity may be accompanied by a sensation of something slipping into place once more. On careful examination the joint may appear to be natural in outline and size, or there may be some swelling. The movements may be free and painless, or limited, and with some degree of pain. It is important to ascertain whether or not fluid is present, and then attention must be directed to the margins of the articular cartilages, to the semilunar cartilages to ascertain whether or not they are movable on flexing and extending the limb, and to the synovial membrane. A most important element in the examination is the question as to the existence or not of abnormal mobility—whether there is any abduction or adduction present, whether the joint is firm in an antero-posterior direction, and whether or not rotation exists. When the knee is flexed, some degree of external rotation is always possible, but internal rotation is absolutely precluded if the crucial ligaments remain intact.

(1) The fatty pads which exist in the joint are occasionally a source of painful trouble. The chief of these pads is that which is known as the ligamentum mucosum, and is situated beneath the ligamentum patellæ, extending backwards as far as the anterior crucial ligament. The margins of this pad on either side are more or less irregular and fimbriated, constituting, according to some authorities, the ligamenta alaria. In addition to these, however, there are to be found in most joints certain tabs or localised masses of fat situated beneath the synovial membrane, and placed above, below, or to the sides of the patella. They are quite irregular in their distribution, but they are not at all uncommon.

Several modifications of these masses are now known to constitute causes of internal derangement.

(a) A patient may suffer from the result of a hæmorrhagic effusion into this tissue, the consequence of a sprain. Thus a man playing football sustained an injury which gave him the sensation as of something opening on the inner side of the knee, which became stiff, but was not "locked." He was able to flex and extend it to some degree. When seen a fortnight later he was complaining of pain, and some amount of tenderness on the inner side of the patella, reaching back along the top of the tibia. There was some general swelling of the joint, increased on walking. Distinct crepitus was obtainable on the inner side of the patella, but no lateral mobility and no displacement of the cartilages when the limb was moved. In this case there was probably a hæmorrhage into the fatty tissue, together with a sprain of the internal lateral ligament. Treatment consisted in massage and exercises against resistance, and was quickly satisfactory.

(b) A little more trouble in this direction will result in the fatty tissue becoming thickened and fibrous; some adhesions may form, so that the patient cannot put his weight upon the limb, complete extension of which becomes impossible. Attempts at walking are likely to lead to recurrent attacks of synovitis, and but little good follows from all the varied methods of treatment that are sure to be employed. There is little that is very characteristic in this form of trouble, but the impossibility of extending the limb fully, and the absence of mobility of the cartilages or of tenderness along the articular line or of the characteristic locking of the joint should be suggestive.

(c) Still another condition associated with these fatty masses is overgrowth to such a degree as to constitute definite swellings on either side of the patella, and these may extend backwards into the joint so as to interfere with the comfortable use of the articulation. The clinical history of such a case has been described

as follows:—The patient meets with an accident in the form of a direct blow or an indirect injury to the knee, which produces severe pain. The joint is, however, not markedly swollen, as a rule, and the pain soon passes off with suitable treatment. The pain returns in attacks generally on the inner side of the joint. The difficulty in flexing or extending the leg varies in different cases. On examining the joint in this later stage one finds that there is a swelling below and on both sides of the patella. This swelling is elastic, and presents pseudo-fluctuation, and the patella floats. The joint is free, and there are no tender spots in the space between the femur and tibia. Treatment consists in the removal of the fatty masses usually by an incision on the inner side of the patella.

A condition somewhat similar to the above, and requiring to be differentiated from them, is that in which the joint is occupied by villous growths of a fibro-papillomatous type, the result either of a simple chronic synovitis or of a chronic osteo-arthritis affection. In this there is usually a considerable degree of effusion, and the trouble may have arisen apart from injury. There are frequent attacks of pain due to the nipping of the villous growths between the bones, and not unfrequently these can be felt and rolled under the finger. There may also be some other evidences of articular disease, such as lipping of the margins of the articular cartilage when osteo-arthritis is present. The treatment of this condition is troublesome and questionable. Under all circumstances the routine method of counter-irritation and improvement of the general health may be tried, together with local pressure and support. Failing this, it may be justifiable to lay the joint open and excise the portion of synovial membrane from which the fringes are derived, usually in close contact with the patella; failing this, excision of the joint may have to be considered.

(2) The semilunar cartilages constitute far and away the commonest cause of internal derangement of the knee-joint. They consist of fibrous tissue covered by articular cartilage, and are attached by their margins to the capsule of the joint; their extremities are fixed to the upper surface of the tibia in front of and behind the tibial spine, the horns of the outer cartilage being placed within the grasp of the extremities of the inner. The inner cartilage is much more often affected than the outer, owing to the fact that external rotation is more likely to occur than internal, and it is the inner cartilage which is exposed to strain in this position. Out of 25 cases of which I have notes, in 21 instances the inner cartilage was involved, in 2 the outer, and in 2 both were so affected as to require removal.

The causation of the injury varies somewhat, but is usually in the nature of a sudden strain or wrench in the flexed position of the limb, to which is superadded some element of rotation. In the football field the accident is not uncommon, the patient slipping or falling violently, and the foot being twisted out at the same time. Sometimes the onset is more gradual, and before any acute displacement occurs there is a history of painful catches in the joint, which are easily put to rights, and may or may not be followed by some synovial effusion. In one case the trouble was evidently due to the rapid growth of the lad, and to ligamentous relaxation. In running and jumping pain of this type occurred, but the trouble was kept in check merely by the use of elastic knee supports. Similarly chronic relaxation of the joint from some affection such as osteo-arthritis may lead in time to displacement.

The character of the injury inflicted on the cartilages varies somewhat, but, for descriptive purposes, may be classified as detachment or loosening, rupture, complete or partial, and bruising. The last of the three will be dealt with separately.

*Detachment and rupture* are frequently associated together. Out of 16 instances of this type of injury, 7 might be looked on as being in the nature of detachment or loosening, whilst in 9 cases the cartilage was torn or split, and perhaps, in addition, loose. The anterior end of the cartilage is much more frequently involved than the posterior owing to the looseness of the capsule in this position, and this will explain why in so many instances the chief pain is to be experienced

close to the inner border of the patella. Rarely is the cartilage completely detached, although that injury is known.

When the cartilage is torn, the rupture may be transverse or longitudinal. In the former instance the two halves may become united again by cicatricial tissue, but the cartilage is henceforth likely to be somewhat loose owing to some increase in length, or it may be fixed to the tibia by adhesions, and pain may result when pressure is placed on it. When the split is longitudinal, the fragment remains attached posteriorly, and its anterior end is loose, being sometimes doubled over backwards, or the free end may even become adherent in the middle line in the inter-condyloid notch of the femur.

The clinical history is a fairly obvious one, but varies a little according to whether the initial injury is sudden or the trouble comes on more gradually. In the former the patient falls to the ground as the outcome of the injury, and realises by the pain that some serious lesion has occurred to his knee. Probably the joint is locked so that he cannot bend or straighten it, and in this condition it may remain for some time, when it may be reduced spontaneously, or surgical assistance may relieve him of the trouble. On examination it will probably be found that some irregularity in outline at the upper end of the tibia is present. The longest time that I have known such a condition persist without reduction was 24 hours, and then the reduction occurred spontaneously, whilst the patient was hobbling about in the street. A sudden snap in the knee relieved the patient from her pain and set the joint free. If such a case with the limb fixed comes under observation, the correct treatment consists in forcible flexion of the limb, perhaps under an anæsthetic, and then in extension, and this manœuvre may be repeated once or twice. As a rule it is immediately successful, as Hey pointed out in his original paper.

The accident will be followed by an attack of sub-acute synovitis with a good deal of effusion, and for this the limb must be kept at rest. As soon as the effusion has disappeared, the limb should be put up in plaster-of-Paris and kept thus at rest for at least three weeks, so as to allow the injured ligamentous attachments of the cartilage to consolidate. At the end of this time massage and exercises against resistance must be instituted, so as to restore the limb to full functional utility, and no strain on the limb, as by athletic exercises, dancing, tennis, etc., should be permitted for another three months at least. In this way it may be possible to obtain a good result without recurrence of the trouble.

If, however, these precautions are neglected, then almost certainly recurrence will follow sooner or later, when the limb is once again exposed to some undue strain. Gradually the intervals between these attacks become shorter; less violence is required to bring about displacement, and the limb becomes more and more weak, and the patient less and less secure in his gait. On examination it will usually be found that there is some thickening of the synovial membrane, together with a point of tenderness near to the patella in the inter-articular line, and on flexing the joint the cartilage may be felt to shift its position, becoming more or less prominent according to circumstances. There is often also some lateral mobility at the knee which is obviously less firm than usual. Under such circumstances, with a history that dates back for some months or years, it is useless to waste time in rest, blistering or other forms of treatment.

In a few cases where the cartilage slips forward, it is possible to control it by means of a support somewhat of the nature of a truss, which consists of two suitably shaped pads which fit on either side of the patella, and are held together by a spring which passes round behind the knee. In patients who live quiet lives this will suffice, although it must be remembered that such a contrivance must be worn day and night, for turning over in bed is not an unfrequent cause of displacement. More frequently, however, operation is to be considered as not only the best, but sometimes the only method of giving relief to the symptoms, and under modern aseptic precautions the patient may be promised a satisfactory result in a short time.

In other cases the onset is more gradual, and may be associated with chronic synovitis, which allows the cartilage to become loosened, and then if some lateral or rotary strain is thrown upon the joint, the cartilage may slip out of place. When once the process has commenced, the story runs on in the same way as outlined in the more acute cases mentioned above.

As regards the character of the operation which is undertaken, but little need be said. The most minute precautions must be taken as to asepsis, and the joint opened on the side where the pain is experienced. Formerly efforts were made to fix the cartilage down to the bone by stitches which passed through the periosteum, and sometimes the cartilage was divided transversely, and the two halves drawn out and thus fixed. It has, however, been demonstrated by experience that these measures are seldom necessary, and that it is wiser to remove the cartilage, or at any rate the loose or detached portion of it, completely. If care is taken to ensure a suitable period of rest, and to follow healing of the wound by massage and exercises against resistance, it is wonderful how strong the joint quickly becomes, and how completely the absence of the cartilage is compensated for.

The removal of both cartilages is another matter, however, and although I have undertaken it once, I cannot say that I was happy with the result, and certainly one will make every effort not to be forced to do so again. The knee necessarily must become "wobbly" with considerable lateral rocking, and in one case to which I have been able to refer, in which the operation had been performed some years previously, a condition of chronic arthritis had supervened which was painful and troublesome.

(... Since this paper was originally written, the case referred to here has been seen again. The patient was a lad of about sixteen, of stunted stature, and there was a typical history with pain on both sides of the joint, which could only be bent or straightened with a jerk, evidently due to the displacement of some considerable body. Both cartilages were loose, and one was torn and much thickened and distorted. Both were therefore excised through two lateral incisions. When healing had occurred, the joint was found to be very loose, with considerable lateral rocking. A hinged splint with firm iron lateral supports was ordered, and after a while the patient was able to get about quite freely and easily, and the amount of lateral rocking had diminished considerably. . . .)

*Bruising* of the cartilages is also known to occur, although it is not common, but I have come across at least two cases of it. In one a clergyman, aged 45 years, a heavily built man, indulged in running and jumping during his honeymoon, an exercise which was somewhat unusual to him, and certainly injudicious. He hurt his knee, apparently not from a fall or slip, but from the jar of a jump over or from a wall. At first it did not give him much trouble, but subsequently he suffered from recurrent attacks of synovitis, with some little effusion, a good deal of swelling, and some pain and tenderness, especially on the inner side of the patella. On examination some months later, after he had been under various forms of treatment, I found that the inner meniscus was decidedly palpable and tender, and seemed to project a little forwards on flexing the knee.

A second case came under my observation twelve months ago. It occurred in a schoolmaster, aged 29 years, as the outcome of an accident during a game at football. He hurt his knee, but played on, and found the limb stiff and painful the next morning. It remained a little swollen and painful for a few days, but there was apparently no effusion. Here, too, there was tenderness on pressure over the external cartilage, resulting in difficulty in extension.

The special features of such cases as these are that the accident is not associated with locking or fixation of the joint, and is not necessarily due to a rotary strain, but rather to the crushing of the cartilage by a fall on the heels, or some such vertical pressure. Nothing serious is thought to have occurred at the time, but subsequently the cartilage becomes swollen and tender, and the patient is unable to stand with a

straight leg. Careful palpation of the joint reveals the swollen structure, which is also tender.

Treatment consists in keeping the limb at rest for a time, and especially from weight carrying. Blisters are useful, and at a later date massage, pressure and exercises against gradually increasing resistance.

The repetition of injuries to the cartilages, either from crushes or displacement and nipping, may be to produce chronic inflammatory changes in the cartilage of a peculiar type, and a chronic arthritis, to which allusion has already been made. Quite recently I operated on a man who came under observation for a cystic swelling on the outer side of the knee, situated exactly on the inter-articular line, and projecting from under cover of the insertion of the ilio-tibial band. It was looked on probably as a cyst or bursa, of which so many are to be found in connection with the knee-joint, and even in unlikely places. There did not seem to be any direct connection with the joint, as alterations in position of the limb did not result in alterations in the tension of the swelling. It was painful, and a cause of weakness and discomfort, and therefore operation for its removal was proposed and accepted. On incision, it was found that fluid of a glairy type, similar to what is seen in bursæ, was present, but that it was contained in a mass of tissue which was continuous with, and, indeed, derived from the external meniscus. To remove the cystic swelling involved also total removal of the thickened cartilage. The result was quite satisfactory. Curiously my colleague, Sir Watson Cheyne, had a similar case to this within a few weeks at hospital, but the condition is obviously rare, as he has only seen one other case, and no other has come under my own observation. The histology of the swollen mass was curious and interesting; but at present we cannot be quite sure as to the exact nature of the process which resulted in the cystic change.

The articular changes which result from the chronic displacement of semilunar cartilages are similar to those known as chronic traumatic arthritis, and are characterised by overgrowth of the margins of the articular cartilages with thickening of the synovial membrane, and perhaps hypertrophy of the villous fringes. A little care needs to be exercised in some of these cases in order to ascertain whether or not a slipped cartilage is present, or whether symptoms of "locking" are due to the nipping of a villous overgrowth. In one of my patients recently there was very marked lipping of the lower end of the femur on the inner side, and a sensation as of synovial fringes rolling under the finger, so much so that I looked on the case for some time as one of osteo-arthritis, and treated it by blistering and rest. When this had failed, and the man came back for further help, one realised that the history of something catching in the joint and of painful locking possibly meant more than this, and although one could feel nothing in the shape of a slipping cartilage, the joint was opened, and I found behind the thickened margins of the bones a loosened cartilage, which was removed with satisfactory results.

3. The articular cartilages are not very frequently the source of internal derangements of the knee. My own experience is limited to two cases, but in each of these there could be no question as to the origin of the trouble.

In one case a portion of articular cartilage, together with the underlying bone, was detached by a process of what the late Sir James Paget described as "Quiet Necrosis," from the substance of the internal condyle of the femur. The patient was a young man, the brother of a house-surgeon, who many years previously had sustained a blow on the knee, when it was acutely bent. In this position the articular surface of the inner condyle becomes much exposed, and a direct blow on the front of the knee will reach it without difficulty. It is quite comprehensible that an injury of this nature could lead to death of the involved portion of cartilage and bone, and that the fragment should be detached quietly into the joint without supuration. In this instance such had obviously occurred, and the fragment had become fixed by a hinge-like adhesion to the lower end of the bone close to its original position. The outcome of this was that sometimes the fragment lay quietly in its old position, or

slipped away happily into the intercondyloid notch; at other times it was caught and nipped between the femur and tibia. The joint was opened and the fragment found and removed by dividing the adhesion. The hole in the lower end of the femur from which it had originally been derived was clearly seen. Such a case might be recognised by the history of a direct blow to the knee, and not a twist or strain applied to the foot; whilst possibly radiography would help in making a diagnosis. Moreover, there would be no spot of localised tenderness, and no looseness of attachment of the cartilages.

In a second case the articular cartilage had become detached in flakelike masses of considerable dimensions in a case of osteo-arthritis. This disease is always associated with cartilaginous changes, but in this instance these had become very exaggerated, and the cartilaginous flakes were abundant and hypertrophic, and were constantly getting between the articular ends of the bones, and giving rise to pain of a more or less characteristic type, suggesting a loose cartilage. There was, however, no history of a strain or of an accident, and the condition of the joint margins might have suggested the existence of the disease. The case was operated on, but naturally although one removed a good deal of the loosened cartilage no good resulted.

Finally, a word of warning must be given as to the possible existence and development of other lesions as a coincident outcome of an injury to the knee which might be expected to lead to some internal derangement. A short time back I was consulted by a young man, aged 27 years, who, eighteen months previously, had sustained a fall from his bicycle, severely injuring the right knee. He seems to have struck the front of the joint, and there was a resultant deep graze. He hobbled home, and was suitably treated, the graze healing quickly, and he was soon able to get about again, though with some discomfort. Four months later he was pushing through a hedge, with the weight of his body resting on the right leg, when something gave way in the right knee, and he fell to the ground owing to the severity of the pain. After lying there for two hours he managed to get home, and was laid up for two or three days. Subsequently he was well enough to cycle and play tennis, though always with some discomfort. After an interval of three months he had a similar experience again, his knee giving out during some effort, and last August he was operated on for a loose internal semilunar, which was removed together with some synovial fringes. He was allowed up at the end of twelve days, and encouraged to move the limb, the result being an attack of synovitis, for which he required the application of icebags in bed for some ten days or more.

When he returned home last September, he was walking much as before, with a good deal of discomfort, and this gradually increased until his limb called for further examination as to the cause of the pain and trouble. When he came under observation in January, 1909, there was a considerable swelling obviously of the lower end of the femur, hard and immobile, and involving the inner rather than the outer side of the bone. This swelling, I was informed, was present when the former operation had been undertaken. X-Ray investigation confirmed the opinion that the swelling was a myeloid sarcoma, and for this amputation had finally to be resorted to. There can be but little doubt that the cause of the myeloid growth was the original fall from the bicycle, and that it had developed coincidentally with the troubles associated with the slipped cartilage. Such a case emphasises the importance of making one's examination of any case as thorough as possible, not being satisfied with merely a superficial investigation, and gives point to the old dictum of Sir William Jenner with which I would close—"There are more mistakes made by want of observation than by want of knowledge."

THE cholera epidemic in the Presidency Hospital, Calcutta has apparently ceased. Altogether 13 Europeans contracted the malady, and of these 10 succumbed. The cause of the outbreak is a mystery as the hospital is the finest in India and has adopted the most modern hygienic methods.

## INTESTINAL SURGERY. (a)

By ARTHUR E. J. BARKER, F.R.C.S.ENG.,  
F.R.C.S.I.,

Professor of the Principles and Practice of Surgery and Clinical Surgeon in University College, London; Surgeon to University College Hospital.

In looking back over a very stirring era and in a great centre of medical progress like Belfast one is led to consider what advance has been achieved in our own science and art during that time. In doing so one is almost bewildered by the multiplicity and magnitude of the strides which have been made in surgery in the present generation. Under the inspiring leadership of Lister conquest has followed conquest, until it may be said that there is hardly a region or organ of the body which has not been brought under the beneficent rule of recent surgery. To attempt a review of these achievements within the last twenty-five years would be a task too great for the present occasion. But if I venture to ask you to recall what has been harvested in one field of surgery, which to many of us in our earlier professional days appeared particularly unlikely to yield fruit, and if I endeavour to trace in broad outline the evolution of those ideas which underlie some of the progressive work which has been done in the surgery of the intestines, it may be profitable and encouraging to fresh effort. For it must be abundantly clear to any seriously-reflecting mind that what has been so far achieved is almost as nothing to what remains to be done. Within the memory of many present to-day any transperitoneal interference surgically with the intestinal canal was regarded as one of the most dangerous undertakings possible. Nowadays, although we look upon all intestinal work as demanding the greatest pathological knowledge, technical skill, and judgment, we know that it can claim an ever-increasing measure of success, especially since we have gained a clearer conception of the functions of the peritoneum.

It is, of course, necessary to be very cautious in applying theories to our practice in surgery of the intestines, but we have, I believe, already received much valuable help from them in regard to operations in the abdominal cavity. We have learnt to be more rigorous in our precautions for warding off sepsis from without during operation, more careful to guard the serous surfaces from all rough treatment during manipulation, and from chemical or physical irritation while exposed, and, on the other hand, more hopeful and bolder in cases where it is already obviously present within the abdomen. We are here thrown back upon the faith of our fathers in the vis medicatrix Naturæ—a power intangible, beneficent, all-pervading, claiming our faith, arousing our hope, but baffling our analysis hitherto beyond a certain point. Yes, we have changed our conceptions of the protective and reparative functions of the serous membranes very much indeed within the past few years, and, as a rule, to the advantage of our patients. We recognise and understand their protective purposes more fully, and are careful to foster and not to impede them. Who would have believed a decade or two ago that the brain and cord may be bathed in virulent septic fluid for days, and yet recover all their delicate mechanisms once more, aided by manufactured antitoxins introduced from without. And none have demonstrated this fact more satisfactorily than the physicians of Belfast in your terrible epidemic of cerebro-spinal meningitis.

Again, the fact established by numerous observers now that this same disease in its severe forms may be recovered from under simple repeated tapings of the spinal canal through the lumbar sac without any injection at all suggests strongly that these serous coverings, too, must possess defensive works of the highest order, only requiring slight assistance in the removal of an overplus of poison to effect a complete recovery in many cases. And this does not apply alone to infection with Weichselbaum's bacillus. Those of us who, like myself, have seen our patients in a state of wild delirium, etc., from cerebro-spinal meningitis starting in the ear, relieved almost at once,

(a) Abstract of Address delivered at Belfast before the British Medical Association July 29th, 1909.

and ultimately recovering completely after repeated withdrawal from the lumbar sac of the products of inflammation, are driven to the conclusion that the powers of defence against bacterial invasion possessed by this cerebro-spinal serous membrane must be very great, and analogous to that of the peritoneum. Once the assurance was arrived at that the serous membranes were on the side of the surgeon and not against him, a long step in advance had been made, and we were encouraged to put forth every power to preserve all its protective forces intact. For it became a matter of observation that these could, under certain circumstances, become exhausted. Prolonged exposure and chill, for instance, or injudicious manipulation or sponging quite apart from sepsis, had been found by experiments on animals and in practice on the human patient to lower the reparative forces of the peritoneum. And besides this, though the peritoneum could be shown to tolerate a certain amount of bacterial poison, it became quite clear that, marvellous as were its powers in this direction, they had their limits, and these could ultimately be reached, even in the case of the less virulent organisms. Another observation which has had an enormous influence upon the surgery of the bowel is that healthy intestinal walls will prevent the migration, to any serious extent, of the bacteria of the contents through them, but that if their vitality is lowered (to use an ordinary term) by accident or disease, even without any breach of surface, this migration will take place through mucous, muscular, and serous coats, and the general cavity of the peritoneum will thereby be infected more or less seriously. This most important discovery—first made upon the fluid found in the sacs of herniæ in various degrees of strangulation and then demonstrated experimentally—has had a greater influence on our dealings with the intestines than is commonly supposed.

Other additions to our knowledge, both theoretical and practical, have also combined to remove many of the risks of intestinal operations. Among these our experience had taught us that patients after such procedures need not necessarily be entirely deprived of food by the mouth for long periods. This, of course, is contrary to the teaching of earlier days. And yet it is in accord with sound theory. Then, during the same period, what improvements in the art of administering general anæsthetics has taken place! The drugs are now purer, the dosage better formulated, and the danger signals during administration better understood. We now recognise that the anæsthesia must be pressed while the peculiarly sensitive parietal peritoneum is being manipulated, and may be reduced or actually omitted during the manipulations and stitching of the practically insensitive intestine. The amount of the drug, therefore, given in these mostly protracted operations is now enormously and advantageously reduced in the hands of experienced administrators. This we owe in a large measure to the recent brilliant demonstrations on the innervation of the parietal and visceral peritoneum by our Swedish and Russian *confrères*. Their discoveries supply us besides with many data of the utmost use in the localisation of lesions in the abdomen by painful impressions.

Another point which has had a remarkable influence upon intestinal surgery has been brought out within the last few years, partly by experimental work on animals, and partly by the experience of surgeons who have felt themselves compelled, for one reason or another, to remove considerable tracts of bowel. We have learnt that considerable lengths of the jejunum, ileum, colon, and rectum can be at all ages removed without any very apparent influence for evil upon the processes of digestion and assimilation. I do not for a moment wish to suggest that we have arrived at final conclusions upon this point. I merely desire to draw attention to the fact that for some of the gravest emergencies in human experience large portions of the intestinal tube have been removed without seemingly producing the deleterious effects which might perhaps have been expected. My own experience of such procedure includes the removal in one case of between 6 and 7 feet of small intestine, in several of between 5 and 6 feet, and several more of lesser amounts of both small and large intestine. In none of these was

there any evidence months or years later that the general health had been in any way injuriously affected. And it has been the same in many published cases, though not in all. At all events, I believe it has been shown that the removal of any amount of small intestine up to 6 feet can be well tolerated. And as far as I know from observation and study of the literature of the subject, age or sex does not influence this conclusion. My own eldest case was aged 76, and here at least 5½ feet were excised, the patient being in excellent health two years later, as was also another case over 50, in which I removed 6½ feet. How much of the large intestine can be removed without demonstrable effects on the health is not yet fully known; but for malignant and tuberculous affections nearly the whole has been taken away or excluded from use, and the patients have enjoyed good health afterwards. I have recently seen one of my own cases in which more than five years ago I extirpated a great part of the colon for malignant disease and excluded the rest, and the patient is now in the most robust health, and without any sign of recurrence, with only the rectum representing the large intestine. Having reviewed some of the factors contributing to our present success in intestinal surgery, let us glance at some of the conditions formerly considered desperate which have been actually relieved during the last decade or two. Among the injuries, punctured and bullet wounds and bad contusions of the bowel have been successfully dealt with; gangrenous strangulations, external and internal, with or without the removal of long pieces of bowel, have been saved; large sarcomata involving intestine have been extirpated, tuberculous tracts of intestine in a hopeless condition of ulceration have been taken away with transient or permanent relief; typhoid ulcers and perforations have been excised, and though only a small percentage of the patients afflicted with them have been saved, owing to the general condition, we must remember that the best authorities tell us that the mortality of typhoid perforation treated without operation is 98 per cent. Intussusceptions operated on at a reasonably early stage are now almost invariably successful. But perhaps the greatest achievements of intestinal surgery have been those gained over the terrible cancers of the bowel, so hopeless and so distressing until quite recently. This evolution of intestinal surgery has not been the result alone of the better conception of sepsis, much as we owe to it. Nor has it been due altogether to improved manipulative skill.

It has resulted from clearer views on the vital processes concerned in all lesions within the abdomen. These we have gained partly from closer clinical observation, aided by what we have learnt from the anatomist, the pathologist, bacteriologist, biologist, and physicist, and from careful sifting of our experiences, whether of failure or success. Looking back, as I have tried to do here, and looking forward, as every hopeful man must and ought to do, we see encouragement in both directions. What has been done within the last few years in this important field of surgery, in spite of the enormous difficulties which surround it, assure us of a far greater yield in years to come, working, as we shall do, under more favourable conditions and with ever-increasing knowledge. Is anyone inclined to despond, thinking, mayhap, of the magnitude of the problems still unsolved and the smallness of his own individual powers in grappling with them, let him listen to the clarion note which rang out just one hundred years ago from one ranking among the greatest philosophic thinkers of his day, and certainly its greatest poet—

Wish upon wish to nobly gain,

Wake up; behold the rising sun.

Those lowering clouds will break in rain;

Rend sleep's brief thrall and gird thee on.

Rouse thee; be bold; and greatly strive.

Heed not the falt'ring, loitering throng.

The lofty soul can all achieve,

Whose thought is swift, whose grasp is strong.

This appeal has since then been finely responded to by his own countrymen, though at the time almost crushed materially and inclined to be despondent. Let us see to it that we, too, undeterred by the languid interest in science of a commercial and materialistic

age, press ever onward, thankful for past achievements in the interests of suffering humanity as we look backward, hopeful and courageous as we look forward to the years to come.

### THE USE OF "ESCALIN" (ALUMINIUM GLYCERINE PASTE) IN GASTRO-INTESTINAL DISORDER (REPORT OF SIX CASES.)

By FRANCIS HERNAMAN-JOHNSON, M.B.,  
B.CH. ABERD., R.N. (RET.),

Late Surgeon, Royal Naval Hospital, Plymouth.

IN the "Medical Annual" for the current year there appears a brief notice of the therapeutic uses of powdered aluminium. The account is culled from German literature, and, so far as I know, the subject has not been given any prominence in English medical periodicals. I therefore venture to publish the following notes, for, though my experience is admittedly meagre, the results obtained by the exhibition of this drug seem to me sufficiently noteworthy to warrant its being accorded a more extended trial.

The preparation, known by the trade name of "escalin," is obtained from Charlottenburg. It consists of a paste made up of two parts finely-powdered aluminium to one of glycerine. The product arrives packed in glass tubes, each containing five small cylinders of the paste wrapped in silver paper. The weight of an individual cylinder is about 4 grammes (dr. i.).

To dispense, I have found the following method to answer well:—Take the contents of one tube, strip off the silver paper, and crush the paste into small lumps. These are then placed in an 8-ounce bottle by means of a scoop, and about an ounce of glycerine and 4 ounces of water are added; the whole is vigorously shaken till all lumps disappear. The bottle is now completely filled, and the "escalin" mixture is ready for dispensing.

Of this mixture, the dose varies according to the severity of the case, from a tablespoonful three times a day between meals to double this amount taken every two hours, with complete abstinence from solid food. The bottle should be well shaken until an appearance like silver paint is produced; the medicine is then poured into a spoon and immediately swallowed. Patients are sometimes rather inclined to look askance at such a peculiar-looking mixture, but a little reassurance is generally all that is necessary to overcome their doubts. The stuff has a sweetish, slightly metallic taste, but cannot be called really unpleasant. The doses above mentioned are considerably smaller than those officially recommended, but I have found them sufficient in my own practice.

**Case 1. Morphia Gastritis.**—E. P., an old lady, æt. 73, suffers from chronic sciatica of a very painful type. A prolonged course of drug treatment, combined with electricity and vibro-massage, having failed to give much relief, malignant disease was suspected. The patient, however, refused rectal examination, and the exhibition of morphia in increasing doses became necessary. After some months of this treatment a severe gastritis developed, presumably due to the morphia. Digestive ferments, preparations of bismuth, and various diets were tried unavailingly; any attempt to reduce the narcotic resulted in a great access of pain. At length, as a *dernier ressort*, I determined to use "escalin." The effect was very marked. In two days the patient was relieved, and in a week's time resumed a solid diet. Similar attacks of gas-

tritis, of which there have been several, have up to the present always proved amenable to the same remedy.

**Case 2. Hæmatemesis.**—F. L., female, æt. 43, is afflicted with exophthalmic goitre. During a course of electrical treatment to the neck the patient suddenly developed a severe attack of hæmorrhagic vomiting. Treatment by morphia hypodermically, bismuth mixtures and liquid diet, gave relief, but a return to solid food caused relapse. Aluminium was now substituted for bismuth, and continued for the same length of time—a fortnight—when solids were again administered. Whether *post* or *propter hoc*, no return of the symptoms occurred, and the patient has not since had an attack (three months).

**Case 3. Gastric Irritability and Entero-Spasm.**—Mary H., æt. 10, was under treatment for chronic infantile paralysis affecting right lower limb. In addition to the local lesion, her general health left much to be desired. Amongst other troubles, solid food nearly always produced violent gastric pain, and not infrequently diarrhoea, within a few minutes of its ingestion. I found that this vicious tendency could be controlled by the administration of tinct. opii, min. iii., half an hour before food; on stopping the drug, however, the spasm returned. Regarding the opium as a somewhat dangerous remedy, I substituted bismuth, without much success. Finally, "escalin" mixture was tried—a tablespoonful t.d.s. between meals. This acted as well as the opium. The aluminium was continued in the same amount for a fortnight, then gradually reduced, and stopped at the end of three weeks. The condition of the stomach and bowels has not since given any cause for anxiety.

**Case 4. Chronic Dysentery.**—M. W., a man, æt. 30, who had been for some time resident in Spain and North Africa, developed a bowel complaint having the clinical features of dysentery. He was advised to return to England, and told that the change of climate would probably effect a natural cure. This prognosis was not verified, and he was compelled again to seek advice. He came to me complaining of chronic looseness of the bowels, tenesmus, and some loss of blood at stool. He was pale and emaciated, and stated that he was rapidly losing weight. Physical examinations failed to reveal anything more than slight thickening of the left colon, together with some tenderness in this region. The stools were fluid, streaked with blood, and contained a few small scybala. A course of grey powder, grs. v., t.d.s., brought away a considerable quantity of hard faecal pellets. By the end of a week the motions were clear of these masses and the offensive smell had disappeared; they continued fluid, however, and occasionally blood-stained. The patient was now placed on "escalin" mixture—an ounce every two hours. On the third day of this treatment blood ceased to appear in the fæces, on the fifth the stools were formed, and by the end of another week the patient was able to begin a cautious return to ordinary diet. The exhibition of aluminium was continued in diminishing quantities for a month, at the end of which time the man appeared to be cured. A slight relapse occurred three weeks later; this was similarly treated, and the patient has since (two months) been perfectly well.

**Case 5. Ulcerative Colitis.**—This occurred in a young woman, æt. 26. Though there was no history of residence abroad, the clinical features were very similar to those in Case 4; they need not therefore be detailed. It must suffice to say that in this instance the diseased area seemed to extend over the whole of the colon, and

the blood was more intimately mixed with the fæcal matter. Six weeks' rest in bed, with careful dieting and the administration of aluminium effected a complete cure.

*Case 6. Mucous Colitis.*—This last I quote as an example of a disease having diarrhoea for its most prominent symptom, in which aluminium was *not* successful; and also, incidentally, as tending to support the theory which refers this complaint to a "neurotic" rather than an "organic" (inflammatory) origin. The patient, a youth, æt. 20, engaged in the study of engineering, began to suffer some two or three years ago from a "nervous" diarrhoea. At first this manifested itself only at periods of special stress—*e.g.*, before and during his professional examinations. Insidiously, however, the trouble developed; it began half-way through the term, then left him free only during vacation, and finally was with him always. When I first saw him he was thin and nervous-looking, afraid to eat, and passing three to four loose mucoid stools daily. There was no blood, and physical signs were absent. Encouraged by previous successes with "escalin," I hoped to find a short cut to a cure. Not the slightest benefit resulted. The disease resisted aluminium as it had defied all previous drug medication. After a month's continuous treatment with full doses, I gave up the attempt, and began a course of abdominal gymnastics, electricity and massage. The patient is now slowly improving.

*Conclusions.*—The use of "escalin" seems to be indicated in all cases where bismuth fails. It should not be prescribed without previously giving older remedies a trial, as it is expensive, even when used sparingly. The action of the drug appears to be purely mechanical, a protective covering being formed over the diseased gastric or intestinal surfaces. The aluminium appears unchanged in the fæces in from six to twenty-four hours after its ingestion. So far as my observation goes, there are no side effects. I have myself taken large quantities as a test, and have never experienced any inconvenience. The harassed general practitioner, struggling vainly with chronic and intractable lesions of the alimentary tract, might do worse than experiment with aluminium glycerine-paste before turning over his cases in despair to the abdominal surgeon.

## THE LEGAL PROTECTION OF THE CHILD IN THE STRUGGLE AGAINST ALCOHOLISM. (a)

By DR. HERCOD,

Lausanne.

OUR century, which has frequently been called "the Century of the Child," and sometimes deserves to be so called, has done very little to protect the child against the ill-treatment to which it is exposed by alcoholic parents. It needed in England the articles of Mr. Sims, "The Cry of the Children" and "The Black Stain," to awaken public attention and provoke legislative intervention which has produced the Children's Act of 1908, that "Grand Charter" of the English child.

The principle of legislative intervention to protect the child is no longer contested, and many States, besides England, have already interesting enactments on this subject.

The research made by the author of this paper relates to legislation in England, Germany, Switzerland, America and Finland.

(a) Abstract of Paper read before the International Temperance Congress, London, 1909.

It includes the following points:—

1. Measures taken to protect the child against alcoholic parents.
2. Prohibiting the giving of alcoholic drinks to children.
3. Children and legislation in regard to public-houses.

### I.

Legislation which allows the drunkard to be put under tutelage or into a special asylum (England, Germany, Switzerland, etc.), provides against the ill-treatment inflicted on a child by an alcoholic parent as a motive for interference. The text indicates less, except in English and American legislation, what is to become of the child whose father has been placed under control or in an asylum. Note the legislative measures taken in Rhode Island, where it is provided that the children of drunkards shall be confided to a special society *at the cost of their parents*. This provision hinders unworthy parents from making use of the State in order to rid themselves of their own responsibility in regard to their offspring.

Unless they are backed by a strong public opinion, the laws in regard to paternal neglect will remain a dead letter. They must, therefore, be enforced with persistence. Temperance societies, in every locality, ought to act as a Vigilance Committee, and make known to the authorities and the press the ill-treatment inflicted on children by drunken parents. They will also point out to the societies for the protection of children the great part that alcohol plays in regard to the ill-treatment of children. The institution of a central committee of the juvenile temperance societies, such as the Swiss "Jugendwerkzentrale" (Central Juvenile Work), might be very useful in this direction.

### II.

In proportion as the special dangers of alcoholic drinks for children are known, the question will be raised as to how far the law can forbid everybody, even parents, to give such to children under a certain age. If, theoretically, such a law is made, it is very difficult to carry it out, because many people regard it as interfering with the family rights, or, at least, as a sort of hateful inquisition, and it is difficult to prove the infraction of the law. It is doubtless for this reason that most of the American laws prohibit any one, *except parents or guardians*, to give alcoholic drinks to children. But such an exception appears to deprive the law of its usefulness. The English law in "The Children's Act" has gone to the root of the problem, and even forbidden parents to give alcoholic drink to their children under five years of age, except in extreme cases. Only to five years, is very little, but the habits of the people must be borne in mind, especially in such conditions as would make it quite impossible to apply the law. The age limit should, therefore, gradually be raised, and in the meantime the parents must be taught the reason why the law has been made. This can be done by the officers of the law, or by doctors distributing cards of instructions at the time when the child is vaccinated, etc.

### III.

All modern legislation seeks to keep children out of the public-house. Sometimes the publican is forbidden to serve drink to children who are not accompanied by a responsible adult (as in most of the Swiss cantons, Hamburg, Wurtemberg, Mecklenburg-Schwerin, etc.). In other places it is generally forbidden to children unaccompanied to enter a public-house (as in Bern, Glaris, Argovie, Oldenburg, Baden, Waldeck, and the greater number of the American States). Unfortunately this prohibition is a dead letter in many countries. The fault is due to public opinion which remains

indifferent, and to the law which provides ridiculous penalties (in Baden 1 to 3 shillings, Appenzell 5 to 10 francs). A heavy fine for the first offence, and taking away the license for a second, would very soon bring the offenders to reason.

The law might go further, considering that the public-house is not a place for children, and it could forbid them to enter, even if accompanied by their parents or a responsible person. Here also the English Parliament has made an innovation, and forbidden children to enter a public-house even when accompanied (Children's Act, par. 120). A similar rule is found in the legislation of Arizona. However legitimate this prohibition may be, it encounters great difficulties. The parents think they are the best judges as to where they shall take their children. Perhaps it would be possible, in order not to offend public opinion too much, which at present is not sufficiently enlightened, to limit the prohibition to the evening hours, but in any case to forbid any drink being served to children, even when with their parents.

In many countries the laws also deal with the employment of children in the public-house, either on account of morality or of health. In Switzerland the age limit is usually fixed at eighteen for girls (in Zurich it is twenty), and at sixteen for boys; but an exception is always made in favour of the publican's family. The German law fixes twelve as the age limit for boys, and thirteen for girls, as far as regards waiting; the children of the publican make no exception except in towns of less than 20,000 inhabitants. The United States have been very energetic in this matter. The State of Wyoming forbids the employment of women and young girls under twenty-one. Connecticut, Idaho, Maryland, etc., the same. Other States allow a lower age.

It seems to us that if women are allowed to serve in a public-house the age of twenty should be the minimum, at least in regard to waiting. For youths eighteen at least. Exceptions in favour of children of publicans are not justifiable, at least in regard to serving.

#### CONCLUSIONS.

1. The children of alcoholic parents, being minors, should be taken from them and confided to the care either of charitable institutions or placed in private families (abstainers if possible). Unworthy parents should be made to contribute to their support if possible.
2. The law should forbid even parents to give their children alcoholic drinks. In fixing the age the state of public opinion must be taken into account. Measures should be taken to make parents understand the reasons for such prohibition.
3. Minors up to the age of eighteen should be forbidden to enter a public-house in order to drink unless accompanied by their parents. An exception may be possible in case of boarders, at meal times.
4. Children under fourteen years of age should not be allowed to enter a public-house after seven in the evening, even if accompanied by their parents.
5. It should be prohibited to employ young women or girls under twenty, and youths under eighteen as waiters, whether they belong to the publican's family or not.

(The figures indicated are approximate.)

## OPERATING THEATRES.

### GREAT NORTHERN HOSPITAL.

APPENDICITIS WITH FOREIGN BODY IN APPENDIX.—MR. ARTHUR EDMUNDS operated on a girl, æt. 22, who was suffering from symptoms of acute appendicitis.

The patient, who was a domestic servant, went to bed perfectly well, but shortly after waking next morning was seized with violent pain in the abdomen and vomiting. She was brought into the hospital, where she presented all the typical signs of an acute appendicitis. The abdomen was rigid, especially over the right iliac fossa; there was marked tenderness, but no definite tumour; the temperature was about 103, the pulse was rapid, and the girl's general facies was quite in accordance with the physical signs.

The abdomen was opened by the usual incision, and a few drops of turbid yellowish fluid came out on opening the peritoneum. The appendix could be felt lying downwards towards the brim of the pelvis. There were no adhesions, and after the rest of the peritoneal cavity had been packed off, the appendix, which was surrounded by a small collection of pus, was hooked up into the wound without difficulty and amputated in the usual manner. The pus was carefully wiped up, and three drainage tubes put in: one into the pouch of Douglas, one into the lumbar pouch, and a third down to the root of the appendix.

The interest of the case, however, Mr. Edmunds said, lay entirely in the nature of the appendix; on examining this after removal, the distal inch-and-a-half was found to be intensely inflamed and covered with lymph. There was a perforation about an eighth of an inch in diameter about the middle of the inflamed portion. The rest of the appendix was normal, and as can be seen by the figure the junction between the normal and inflamed portions of the appendix was quite sharply marked. On slitting open the appendix, the distinction between the two portions was, if anything, more pronounced, and in the lumen of the inflamed part there was an ordinary black steel pin, not particularly corroded, with its head lying at the very end of the appendix, and its point reaching exactly to the junction of the inflamed and normal portions. Several points naturally, Mr. Edmunds remarked, presented themselves for consideration; in the first place, the exact limitation of the inflamed area to that portion of the appendix containing the pin was very striking, but against this it must be remembered that it is quite common to find the terminal portion of the appendix acutely inflamed, while the proximal three-quarters of an inch remain absolutely normal. The relationship between appendicitis and the presence of foreign bodies in the appendix was difficult, he thought, to determine, for, although it has taken a great hold on the popular imagination, it must be confessed that cases like the present were extremely rare; also that appendicitis is very common without a foreign body, and that a large number of cases have been collected where foreign bodies have been found post-mortem without any signs of appendicitis. It was possible, therefore, that the presence of the pin in this case was simply a coincidence. From the look of the pin, its presence in the appendix was of comparatively recent date, and the absence of all history of any previous intestinal disturbance suggested that this was the first attack, and that the onset of the symptoms coincided with the perforation of the appendix. This perforation was not near the point of the pin, which, from its position, must have slipped in from the large intestine head first, so that there was no reason for associating the perforation with any gross lesion produced by the pin itself. It was possible, however, that the presence of the foreign body started an inflammation which was kept up by infection from the bowel, the site of the perforation being determined by the vascular distribution in the organ. The patient is now progressing favourably.

## SPECIAL REPORTS.

### THE SEVENTY-SEVENTH ANNUAL MEETING OF THE BRITISH MEDICAL ASSOCIATION AT BELFAST.

[FROM OUR SPECIAL CORRESPONDENT.]

THE SECTIONS (*Continued from our last*).

#### Ophthalmology.

Two interesting discussions were held in this section, and both were well attended. The first was on the WORKMEN'S COMPENSATION ACT AND EYE INJURIES. It was opened by Dr. Freeland Fergus, of Glasgow, who discussed the usefulness of mathematical formulæ in expressing the value of varying degrees of vision. He came to the conclusion that such formulæ were not of much use, as the kind of sight required in different classes of work varied so much. In some trades visual acuity is of the first importance, while in others it is only of secondary importance, the capacity for work depending on a good light sense and good alignment.

Dr. Cecil Shaw (Belfast) said I desire specially to deal with the unsatisfactory working of the Workmen's Compensation Act with regard to compensation for the loss of an eye. According to the Act, no compensation is given for such loss, but only for partial or total incapacity for work. Where one eye is lost and the other is healthy, a man soon learns to work with one eye, and in the great majority of cases work can be done quite as well as before. I know of four men in this district who are daily driving motor cars, in spite of having lost an eye, and one of them, a professional chauffeur, told me that six months after the accident by which his eye was lost, he had forgotten all about it. According to strict interpretation of the Act, such cases should only obtain compensation for the few months that elapse before they are fit for work again. But the true injury in loss of an eye is not generally any loss of capacity for work, but lies in the greatly increased risk of total blindness owing to disease or accident in the other eye. Every one is liable to such disease and accident, but to the one-eyed man it is a much more serious event than to the man who has another eye to depend upon. Owing to this many employers avoid one-eyed men, since a slight accident to one eye may totally incapacitate them. Even though perfectly fit for work they may fail to obtain it on this account. An interesting case occurred in my experience a short time ago, of which the facts were briefly as follows, I believe.—A working girl lost an eye by accident, and after some months' incapacity, for which she received compensation, she returned to her work, which she was able to do efficiently. But when slackness of work arose, and she had to seek work elsewhere, she could not get a job, on account, as she believed, of her being one-eyed. She then brought an action for compensation, but it was pointed out that there was no ground to go upon, since there was no incapacity, as proved by her having worked at full wages for some months after the loss of the eye. I believe that a better form of compensation for the loss of an eye would be a sum fixed according to the average wages, to be paid irrespective of all theories or statements about a workman's capacity for work. The endless litigation involved in such cases benefits the great learned professions, no doubt, but it involves serious loss to the workmen, for whose benefit the Act was passed, and out of whose pockets eventually the cost of the litigation comes.

The discussion was continued by Dr. Brailey (Hove), Mr. Bishop Harman (London) and others. Professor Fuchs discussed the Continental methods of dealing with compensation claims. Sir Victor Horsley and Mr. Berry (Edinburgh) both agreed with Dr. Cecil Shaw that persons who lost an eye quickly learned to work well with monocular vision.

The second discussion was opened by Mr. Treacher Collins, and was on

#### DISEASES OF THE LYMPHOID TISSUE OF THE CONJUNCTIVA,

and resolved itself into a discussion upon trachoma, in which Professor Greef (Berlin), Professor Fuchs

(Vienna), Dr. Nelson (Belfast), and many others took part. Professor Fuchs seemed to have little doubt that the true trachoma germ had at last been found. It appears first in the mucous membrane of the upper retrolarsal fold, and lingers there longest.

Sir Victor Horsley read a highly technical paper on "Optic Neuritis," which provoked a lively discussion. Dr. W. M. Killen (Belfast) read a paper on the association which he believes to exist between asthenopia and adenoids.

#### Naval and Military Section.

In this section a paper by Colonel James, R.A.M.C., was read by Captain Cunningham, on the "Officers' Training Corps," with special reference to its medical branch. He said that in case of war the Army Medical Department would have to be increased to about double its permanent size, and a large call would be made on the civil medical profession. He proposed to make use of the Officers' Training Corps as a means of forming a medical reserve to call upon in case of need.

Lieutenant-Colonel Potter, R.A.M.C., read a paper on the "Physical Training of Recruits." He described the present methods of physical training, which, he said, were based upon the Swedish system, and differed entirely from those in use a few years ago. The great aim used to be the production of enormous masses of muscle, while now it is the harmonious development of the whole organism, and the promotion of the utmost efficiency in its working as a whole. At the conclusion of the paper a practical demonstration of the methods was given on a party of recruits sent up from the Victoria Barracks for the purpose, and Colonel Porter answered a number of questions as to details.

#### THE MEDICAL LIBRARIES ASSOCIATION.

The annual meeting of the Medical Libraries Association was held on July 28th, in Queen's University, Belfast. After the transaction of some purely formal business, the President, Prof. W. Osler, F.R.S., delivered an address on the "Medical Library as a Factor in Post-Graduate Work." A large and representative gathering was present, which in a most enthusiastic manner showed its appreciation of the eloquent address. In conjunction with the meeting an exhibition of over two hundred valuable and interesting medical MSS. books, photographs of libraries, etc., was held in the Engineering Drawing Room from July 27th to 30th. The exhibition was divided into seven sections. Two MSS. in Section 1 called for special attention, an English one of the 14th century, on urine (Manchester Medical Society), and another on the same subject, about the same date, in Latin and Irish (Trinity College, Dublin). Section 2 contained fifteen volumes printed before 1500, amongst them the first edition of "Celsi de medicina liber," 1478 (Dr. Lloyd Roberts), the works of Mesue, 1478 (Bristol Corporation), the surgery of Guy de Chauliac, 1480 (Manchester Medical Society), and the "Anatomia of Mundinus," 1493 (Dr. Lloyd Roberts). Amongst the books printed since 1500, Section 3, were two copies of Raynalde's "Birth of Mankind," 1528 and 1613 (Dr. Lloyd Roberts and the Bristol Medical Library), Faier's "Regiment of Lyfe," 1567, Paynel's "Regimen Sanitatis Salerni," 1541 (both by Dr. Lloyd Roberts), and a pamphlet on "Variolous Contagion," 1808, by Jenner (Prof. Lindsay). An exceptionally fine collection of books by Irish authors, or printed in Ireland, formed Section 4, lent principally by Dr. Kirkpatrick, of Dublin, and the R.C.P.I. Prof. Osler had lent two interesting collections of books relating to Michael Servetus—whose quartercentenary occurs this year—and Ulrich von Hutten, the scholar-knight, who described the treatment of syphilis in his own person. The final section contained a series of books on consumption, commencing with Celsus, who recommended an open-air treatment and milk diet, and ending with the Countess of Aberdeen's "Ireland's Crusade against Tuberculosis."

The following were also among the contributors:—Royal College of Surgeons of England, Steeven's Hospital, Dublin, Sir W. Whitla, Dr. W. L. Storey, Mr. R. M. Young, Ulster Medical Society, Dr. Marion Andrews, Mr. E. G. Clayton, Queen's University,

Belfast, Linen Hall Library, Belfast Corporation, Dr. Parker, Bristol, Bristol Medical Library, Mr. Swanston, Belfast, and Mr. Somerville, Sheffield. Messrs. Bell and Mayes had also most generously loaned a number of cases.

#### ANNUAL TEMPERANCE BREAKFAST.

The annual temperance breakfast in connection with the meeting of the Association was held in the Central Hall of the Municipal Technical Institute on Thursday morning, July 29th, and was attended by between 300 and 400 guests. The Lord Mayor (Sir Robert Anderson, J.P.) presided, and welcomed the members present to Belfast. He expressed his warm interest in the temperance question, of which he is an ardent supporter. (Probably a good many visitors were surprised to find in Ireland a Lord Mayor who had the courage of his convictions in this matter, and gave no alcohol in any form at his entertainments, either public or private.) Dr. Kelynack, Hon. Sec. for the Society for the Study of Inebriety, gave an interesting address, in which he summed up the proceedings of the International Conference on Alcoholism which had met in London the previous week. Dr. Crothers (an American visitor), Dr. Norman Barnett (Belfast), Mr. McAdam Eccles, F.R.C.S. (London), and others also spoke.

#### THE GOLF MATCH.

One of the most interesting events of the Belfast meeting was the presentation of the Belfast Golf Cup, which took place at the Annual Dinner, and the first match for the cup, which was held at the Royal County Down Golf Club's links at Newcastle on Friday, July 30th. The cup was presented to the President of the Association by Mr. Kirk, the President of the Ulster Medical Society, on behalf of the golfing members of that Society, who had subscribed for it. At the match on Friday the members competing, who numbered over one hundred, were entertained to luncheon by Mr. and Mrs. Kirk, and afterwards to tea by Dr. R. L. Bell, of Newcastle, in the Club House. The match resulted in a win for Dr. Shekleton, of Holywood, who was 2 up on bogey. The play over the Newcastle course, which is probably the most difficult first-class course in the United Kingdom, was a trying ordeal for many of the visitors who had never seen the links till that day.

#### THE EXCURSIONS.

In accordance with the usual custom, Saturday following the meeting was devoted to excursions, of one or other of which a great number of the members availed themselves. They were three in number. Portrush and the Giant's Causeway was naturally the most popular and largely attended. Portrush was reached about 11 o'clock, and after light refreshment the electric tram was taken to the Causeway, where about three hours were spent. Happily, the day was fine and calm, so that many members were able to go out in the boats and see the Causeway and surroundings in the best possible way. In the afternoon the tram was taken back to Portrush, where a late luncheon was provided. The second tour was to Parkmore and round the Antrim coast to Larne, by the famous Coast Road, stopping for lunch at Garron Tower Hotel. The third excursion was to Warrenpoint, where the party was entertained by the Warrenpoint Urban Council, who took them a trip on the beautiful waters of Carlingford Lough. The whole arrangements for the excursions were carried out without a hitch by Messrs. Thos. Cook and Sons, under the superintendence of Dr. R. J. Johnstone, Hon. Sec. of the Excursion Committee.

#### THE EXHIBITION OF FOODS, DRUGS, INSTRUMENTS, ETC.

The annual exhibition of instruments, drugs, etc., was held in the Exhibition Hall of the Botanic Gardens, most conveniently situated at the back gate of the College grounds, so that members could drop into the exhibition at odd times for a few minutes. The hall is large and airy, and both exhibitors and visitors greatly appreciated the comfort of it. Taken as a whole, the show was excellent, and well repaid careful study. It is only possible here to notice a few of the more striking exhibits, and many of interest must be omitted for want of space.

Just inside the main entrance was one of the largest

exhibits, and one which many members were glad to see again, after several years' absence from the annual exhibition—that of Messrs. Burroughs Wellcome and Co. In addition to the well-known products with which all medical men are familiar, the firm showed a number of recent introductions and improvements. The advantages of Ernutin, the active principle of ergot, are widely recognised, but a new preparation of ergot has lately been introduced, and was shown under the trade name of Tyramine. This presents the chief active constituent of aqueous extract of ergot, the organic base, which is produced by bacterial or other ferments from the amino-acid tyrosine. Tyramine may be used for raising the blood pressure in shock or collapse, and for producing contraction of the uterus post-partum.

The arylarsonates are also important additions to the products of the firm, made as a direct result of recent researches. These organic preparations of arsenic have been used with benefit in trypanosomiasis, syphilis, and malaria. "Soamin" contains 22.8 per cent. of arsenium, and is soluble in five parts of water at 60 deg. F., giving a neutral solution which can be sterilised. "Orsudan," another preparation, is even more remarkable for its low toxicity relative to its percentage of arsenium. Recent experiments indicate its usefulness in malaria.

The various serums and vaccines produced by the firm are well known, and fresh additions are constantly being made. Needless to say, hypodermic medication and toilet specialities made a good show.

Messrs. Savory and Moore had a fine exhibition of infants' and invalids' foods, including their well-known peptonised preparations, of which several new forms have lately been introduced. Their excellent "Valveless" feeder was also shown.

Messrs. Hoefftke, Ltd., showed various appliances for joint diseases, extension of the spine, etc., and also their highly ingenious "auto-gloving machine," by which a rubber glove can be put on without being touched on the outside at all.

The Maltine Manufacturing Co. showed the many varieties of malt preparations for which they are so widely known, as well as Carnrick's "Beef Peptonoids."

Plasmon, Ltd., showed that useful proteid in apparently unlimited and protean forms, including Plasmon tea, cocoa, oats, arrowroot, custard, biscuits, chocolate, and beef-tea.

Messrs. Parke, Davis and Co. had a fine exhibit rightly classed as "modern therapy," as it included the most recent improvements in their various productions such as chloretone, eudrenine, sprays and inhalants, hypodermic syringes and drugs, and serums of all sorts. The preparation of the different things shown was described in short lantern demonstrations which were given at intervals all day.

The Chas. H. Phillips' Chemical Company exhibited their now well-known and admirable milk of magnesia as well as their excellent tonic and anti-periodic "phospho-muriate of quinine compound."

The Bayer Company showed many of their well-known products, such as aristol, aspirin, brotargol, etc., and several new preparations. Among the latter was Guaiacose, a tasteless, odourless, and non-toxic compound of guaiacol for use in the respiratory tract. Thyresol, a methyl-ester of santalol, used in gonorrhoea, was also shown. It is said to be less toxic than sandalwood oil, and less irritating to the stomach.

Chas. Hearson and Co. showed several of their biological incubators with patent temperature regulation, including new forms for Opsonic work, and some heated by electricity. Centrifuges were also shown, among them the "Copenhagen Model," giving 9,000 revolutions a minute.

Siemens Bros. and Co. showed a great variety of electrical apparatus, comprising complete X-ray outfits for private and hospital use. Their Universal and Safety Protective Tube Stand seemed to be a most convenient and complete piece of apparatus. They also showed a clinical temperature recorder by which the temperature of patients can be continuously recorded at stated intervals, as, for instance, every 12 minutes for many days, or even, for special investigations, every quarter of a minute.

The Apollinaris Co. showed Apollinaris, Apenta, and

Johannis waters. One wonders if there are any medical men in the country who are not already familiar with at least the two former, but presumably among the host of new waters the old favourites are liable to be forgotten if they do not show themselves.

Messrs. Armour and Co., who describe themselves as specialists in high-testing digestive ferments, showed an absolutely bewildering array of pepsins, pancreatins, enzymes, peptones, bone marrow, suprarenalin, trypsin, lecithin, and the glandular extract of each and every organ in the body. After these, the plain extract of beef by the same manufacturer seemed flat, though some old-fashioned visitors might be inclined to say it was worth the lot!

Fairchild Bros. and Foster showed a very similar range of products, beginning with acid extract of duodenum, and ending with zymine.

The Sanitas Co. showed Sanitas Fluid and its many derivatives for household and hospital disinfection "of all co-efficiencies of all kinds and for all purposes." Their latest introduction is Sanitas floor and furniture polish, which sterilises all wood upon which it is smeared.

Mellin's stand was, as always, particularly attractive to lady visitors, for not only are the biscuits, chocolate, etc., most tempting to the modern Eve, but the photographs of Mellin babies are an endless source of interest.

The Cellular Clothing Co. had an excellent exhibit of their underwear, including their new red garments for use in the Tropics, where they are believed to stop the penetration of the blue actinic rays of the sun, now credited with the production of sun-stroke.

Jeyes' Sanitary Compounds Co. showed their non-toxic bactericide Cyllin, and its many derivatives, such as cyllin gauze, wool, powder, ointment, etc. The basis, cyllin, is guaranteed to be at least ten times less toxic than carbolic acid, and to have a very high efficiency as tested with various harmful micro-organisms.

Bovril and Virol do not depend upon the attractions of novelty, but upon the well-trying friendship of years, so that there is nothing much to be said of their exhibits, except that they are as neat and attractive as ever.

Messrs. Grattan and Co., of Belfast, had a good show of their various aerated waters, which, though not pushed or advertised as widely as many others, are generally considered in Belfast as hard to equal and impossible to surpass.

The hot springs of Bath are not leaving everything to the foreigner, and are now showing an enterprise which, if it had stirred a few centuries earlier, might have resulted in a most useful testimonial from Julius Cæsar or King Alfred. But better late than never, and every patriotic Briton must be glad to see the excellent exhibit made now, which ought certainly to result in a wider use of these fine baths.

Brand and Co. and Cadbury and Co. are among our old friends, whose useful preparations we welcome each year.

Messrs. Down Bros. had a very large exhibit of surgical instruments and apparatus, chiefly new and original designs carried out by them at the request of various surgeons. The number of items in their list is far too large for them to be recounted. One cannot help wondering how many of them will be in use five years hence! The survival of the fittest is never better illustrated than in these instruments, many of them mere modifications of old patterns, and some simply old patterns revived without any modification whatever. But old or new, the same care and skill are expended on their manufacture, and the exhibit was a credit to British workmanship. The hospital furniture shown by this firm was of great interest, specially various forms of operation table.

Messrs. John Weiss and Son showed a large collection of surgical instruments of all the latest patterns, such as Brunig's and Killian's for Bronchoscopy, etc., also Barker's, Moynihan's, Landolt's, and other recent introductions.

Messrs. Mayer and Meltzer showed all their latest introductions, including improved patterns of their well-known University electric examination lamp, and

a very complete collection of instruments for throat, nose, and ear work, both hand and electro-motor.

The Holborn Surgical Instrument Co. had a large exhibit of surgical instruments of every description. A number of sets of instruments for special work of various descriptions were shown, and at prices more common in Germany than in London. The glass-ware and sundry small fittings for consulting-room or hospital extern were very attractive.

Frank Rogers showed a very interesting assortment of sprays and atomisers of every description. The sets of sprays for aqueous and oily solutions on stands for consulting-room use were specially neat and ingenious. A new and apparently very efficient chloride of ammonium inhaler was also shown.

Messrs. Jas. Woolley and Sons, of Manchester, showed a great variety of modern pharmaceutical preparations, appealing specially to those who dispense their own drugs, etc.—work which is simplified and facilitated by their concentrated mixtures. They also showed various instruments and pieces of apparatus, such as their ingenious "Fotoret" electric lamp, and their "Victoria" sterilising outfit.

Messrs. Oppenheimer and Co. made, as usual, a special feature of their Aeriser in its various forms. The new foods and drugs shown included Roboleine, said to be "a really complete scientific food," and Mergal, an organic salt of mercury for use in syphilis.

Messrs. Bailliere, Tindall and Cox, Appleton, Frowde, Lewis, Lippincott, Rebman, Saunders, Wright, and others showed all the latest medical publications, a great boon to country practitioners who cannot often visit a good book-shop.

It only remains to be said that from all accounts a large amount of business was transacted, and that both exhibitors and visitors seemed satisfied with the general arrangements.

*(To be concluded in our next.)*

## CORRESPONDENCE.

### FROM OUR SPECIAL CORRESPONDENTS ABROAD.

#### FRANCE.

Paris, August 8th, 1909.

#### ULCER OF THE CORNEA.

THE treatment of ulcer of the cornea is in general very tedious; Roure recommends the application of a one per cent. solution of formol twice a day on a piece of absorbent cotton after introducing a few drops of a solution of cocaine. In the interval of dressing the eye should be kept covered. The progress of the cure can be verified in touching the lesion every three or four days with a solution of methylene blue, which only stains the parts deprived of epithelium. Where no stain is observed, the ulcer is cicatrised and the application of formol may be suppressed.

Cacodylate of soda has also been used with benefit: an ointment of two or three per cent. is applied to the lids every night for a week, and afterwards every second night.

Besides the ointment, five drops of a three per cent. solution are instilled every morning for a fortnight.

Under the influence of this treatment, the ulcerations heal rapidly.

#### PULMONARY TUBERCULOSIS.

While the world is anxiously waiting for some specific treatment for the plague of humanity called consumption, efforts are constantly being made to arrest as much as possible the inevitable disintegration of the organism affected with that dread disease.

Among the multitudinous remedies recommended of recent date may be mentioned injections of camphorated oil (1-10) into the middle of the back, repeated twice in four days, with an interval of ten days between every new series of injections.

According to Prof. Koch, the night sweats disappear and the weight of the patient increases under the influence of the treatment. At the same time he recommends rubbing the skin with a drachm of an ointment composed of camphor, Peru balsam, and oil of eucalyptus.

M. Renon said injections of an ounce of marine serum once or twice a week increase the weight and appetite and improve the general condition. Fever is a counter indication to this treatment.

#### HÆMOPHILIA.

Where injections of gelatin, adrenalin or ergotin remain without effect on the hæmorrhage, excellent results can be obtained from injections of anti-diphtheritic serum.

#### EXOPHTHALMIC GOITRE.

Perhaps the best treatment of this curious affection would be at each meal a teaspoonful of hæmato-ethyroidine during 15 days, and recommenced after a few days' suspension. At the same time, the patient should be advised to himself apply an electric treatment with a simple faradic battery, one electrode at the back of the neck, the other moved over the thyroid tumour. This treatment should be followed for months.

Powder of hypophyse or the pituitary gland in three grain doses before each meal might also be utilised.

Weber recommends pills (three daily) of arsenious acid and corrosive sublimate, one milligramme each (1-64 gr.), for several weeks.

#### TINCTURE OF IODINE.

Cases of poisoning by tincture of iodine swallowed accidentally, or with suicidal intent, are not rare.

Once in a while every practitioner has had to treat such accidents, and different antidotes have been tried after a preliminary evacuation of the stomach by a simple vomitive or the stomach pump. It is thus that a mixture of starch has been given with a view of converting the iodine into iodine of starch, mucilaginous drinks and injections of morphia to ease the pain.

The best antidote is, however, hyposulphite of soda by which the iodine is transformed into tetrathionate, a non-toxic product and well-known to chemists. A solution of 10 per cent. of hyposulphite is sufficient, according to Dr. Lemaire, to discolour half of its weight of tincture of iodine. Its employment is easy: in case of local accidents, compresses of the solution will remove the excess of iodine without irritating the teguments.

For poisoning by the mouth, the patient is ordered to swallow by sips the solution between the seizures of vomiting provoked by the poison; in passing down the throat and the œsophagus, the counter poison neutralises the action of the iodine on the mucous membrane, and is afterwards rejected in the vomiting, which is first of a yellow or bluish colour, and finally becomes colourless.

The efficacy of hyposulphite of soda as a counter poison resides not only in the rapidity of the neutralising action, but also in its innocuity. It has also the advantage of being easily obtained. It is found in every drug store and with those, and they are legion, who practice the art of photography.

Hyposulphite of soda is also useful for removing the stains of tincture of iodine from the hands, linen, etc.

#### CATAMENIAL PAIN.

Acetate of ammonia	...	1 oz.
Tr. of piscidia erythrina	...	5 dr.
Tr. of viburnum prunifolium	...	5 dr.
Tr. of valerian	...	5 dr.
Tr. of anemone pulsatilla	...	2 dr.

From 2 to 5 teaspoonsful a day in a little water.

### GERMANY.

Berlin, August 8th, 1909.

At the Medical Society, Hr. Hamburger spoke on COLOURING THE LIVING HUMAN EYE FOR DIAGNOSTIC PURPOSES.

He mentioned fluoresceine, introduced by Ehrlich into physiology, a material which, injected into animals subcutaneously, had the property of imparting a green colour to fluid of the anterior chamber of the eye. Ehrlich himself, as well as Leber, later coupled this with observations on intra-ocular tissue change and renewal, and applied the conclusions drawn to man, but, as the speaker thought, incorrectly. The attempt to inject fluoresceine into the human subject was only made once, and showed that it was dangerous. On the

other hand, however, he had given fluoresceine-sodium (uranine) to many patients by the mouth in increasing doses—6 to 8 gm. for adults—without the least harm. After giving it, intense jaundice set in; the saliva became green, and the urine red. These symptoms disappeared in at most 12 to 24 hours. The colouring matter never passed into the healthy eye, but it did into one that was inflamed in its interior, and the more the eye was inflamed the more intense was the colouration; on subsidence of the inflammation the colourability also subsided. Inflammations of the conjunctiva, however severe, did not lead to colouring. The disease must be intra-ocular. The observation showed that tissue change within the eye progressed very slowly, that in the inflamed eye it was accelerated, and, further, that experiments made on animals were not necessarily applicable to the human subject. In practice the fluoresceine experiment was not without value when in doubtful cases it was difficult to determine whether the interior of the eye was inflamed or not.

Hr. Paderstein showed a man who had a splinter of iron in the lens. It was quite easily recognisable, as the other parts of the lens were perfectly transparent. Extraction with the magnet presented no difficulty, but removal would leave a traumatic cataract behind. As the patient had lost one eye through a similar accident some years before, the speaker had come to the conclusion of leaving the foreign body where it was until it set up some kind of disturbance.

At the German Society for School Hygiene (tenth annual meeting), Prof. Best, Dresden, spoke on PROTECTION OF THE EYE IN SCHOOL AND HOME.

He was of opinion that the reaction of the youthful eye to eye-strain was the development of short-sightedness, the only morbid change that was to be feared during growth of the eye, as the result of intense eye work. The protection of the growing eye against overwork was therefore identical with combating short sight. In this warfare near eye work under unfavourable and unsuitable conditions must be avoided; further, the length of time of the near work must be limited, by lessening the tasks, by a changed method of learning, and by reduction of home tasks. A certain diminution might be made in the amount of matter to be learned. For instance, there was no need to learn four alphabets. Italian letters, printed and written, were all that were necessary.

Hr. Lehrer Graupner, Dresden, desired that for proper lighting of desks the sky should be visible from each one through the upper panes of the window at a distance of at least 40 cm. As writing at first required some fixity in the work, it should be more and more relegated from the elementary classes; furthermore, everything that made eye work difficult should be done away with—too sloping desks, double lines, network lines, etc. The Italian and German alphabets were to be built up on the most simple foundations, and in writing they should be made to assimilate to each other more and more. Elementary reading could be founded on a preliminary course, by which the analysis of sound and the synthesis of consciousness of sound might be awakened in the child. If a commencement were made with the Italian alphabet, instead of 78 signs there would only be 37 to start with. Manual training also required careful supervision.

Hr. Hauptmann v. Ziegler observed that every year Germany lost the services of 9,000 defenders through visual defects. Short-sightedness brought on by long-continued near work might be avoided by practising distant vision; eye gymnastics should therefore be practised in school, and in the school playground by looking at distant objects, in association with games and walks.

### AUSTRIA.

Vienna, August 8th, 1909.

#### THE BOWEL AS AN OSMOTIC MEMBRANE.

At the Gesellschaft der Aerzte, Pribram gave a long explanation of his experiments in the laboratory on absorption in the bowel under different pathological conditions. He first demonstrated the bowel to be a colloidal membrane whose permeability in the case of crystalloids is rapid in health, but in chronic

enteritis this function is greatly reduced, but in acute enteritis the opposite is the case. This is an important maxim to be borne in mind by the clinician, particularly in cases of children where the osmotic function is of such consequence. It is well illustrated in the latter where galactosuria accompanies a sharp attack of enteritis in the febrile stage with a profuse elimination of salines and sugar, but as soon as the storm is over a generous diet will rapidly restore the child to its former condition.

Pribram, although confirming the fact that crystalloids are rapidly absorbed in acute forms of bowel complaint, affirms also that colloids are no exception to this speedy osmotic absorption. He finds albumen, ferments, and toxins more rapidly absorbed and diffused by the acute inflamed bowel than when in the healthy condition.

Clinically, he thinks this teaches us to abstain from salines and saccharine fluids in acute enteritis, but administer them freely in chronic cases of enteritis in order to restore the bowel to a healthy osmotic state.

#### PRESERVING HUMAN MILK.

Mayerhofer next raised the question of preserving human milk for feeble babies where a wet nurse could not be obtained. He proposed a modified form of Budd's method, by putting 0.1 of a centimetre of peroxide of hydrogen in 400 cubic centimetres of mother's milk. If the milk were acid a little superoxide of magnesia would relieve this. This method has been adopted in Kaiser Joseph's Hospital with perfect success. It is quite possible in this way to preserve the complete nutritious quality of the milk as well as its sterilisation for months at a time, thus emancipating the nurse who has hitherto been the infant's slave while the child is receiving its natural food.

Escherich said he would criticise Pribram first. His experiments opened up a new field of investigation as he has conclusively proved a difference in the power of absorption in chronic, natural, and acute conditions of the bowel, which is a confirmation of Meyer's results; but we must not err in our haste to immediately act on these results till we have eliminated all possible errors. What is the difference in the epithelial cell of the bowel before and after the bowel has been disturbed for the experiment? This might make a difference in the osmotic function of the bowel of the child after death as well as that of the guinea pig, *i.e.*, the living organism *in situ* may be functionally different than in these laboratory experiments.

As for Mayerhofer's budderised human milk it will be of little practical value. No doubt in weakly children with neither mother nor nurse, coming to hospital, this conservation may be of some value, but for the practitioner it is a hopeless innovation.

Hochsinger thought the idea of budderising human milk was a good one, as the mother's milk was often quite unfit, from its acidity, for the alimentary canal of the infant when drawn from the mother with the exhaustor and disinfected, the danger to the child is less. It is found in practice, however, that when a milk exhaustor is used the secretion subsides, not having the stimulus of the child. To counteract this defect Jashchke has devised a milk pump to effect this stimulus.

Teleky could not see much benefit to be derived from Mayerhofer's budderising as many mothers could not complete the feeding of baby, while other healthy mothers may be quite able to give a large quantity beside nourishing their own children and without damaging health, but the question arises: Is it wise?

Pribram, in his reply, said the operations carried out in the guinea pigs were as nearly natural as could be, as very little of the bowel was disturbed from its attachment. In the bowels of the children he admitted they were post-mortem, but they agreed in every detail with the bowel of the live animal in the same experiments.

In answer to the criticism on the milk conservation he never found the milk supply from the female diminish prematurely by using the breast exhaustor, on the contrary it was increased.

As to the exhaustion of the female it was the duty

of the collector to select strong, healthy mothers, and see them kept in that healthy condition. Extraction from feeble mothers was not to the benefit of either mother or child. The experiment is only in its initial stage, and cannot be accepted as a palladium until further experience proves all that is claimed for it.

## FROM OUR SPECIAL CORRESPONDENTS AT HOME.

### SCOTLAND.

EDINBURGH UNIVERSITY, NEW PROFESSOR OF ANATOMY.—The curators have unanimously elected Professor Arthur Robinson, of the University of Birmingham, to succeed the late Professor D. J. Cunningham. Professor Robinson graduated at Edinburgh with honours in 1883, and in 1890 was awarded a gold medal for his M.D. Thesis on "The Development of Rodents." After graduating he demonstrated anatomy at Surgeons' Hall, Edinburgh, and thereafter assisted Professor Turner in the University. In 1884-5, owing to the illness of the late Professor Morison Watson, he undertook the practical teaching of anatomy at Owens College, and he remained in Manchester until 1896 in the capacity of demonstrator at Owens College, and subsequently lecturer in the Victoria University. He left Manchester for the Middlesex Hospital Medical School, where he entirely reorganised the anatomical department, and left it second to none in the Metropolis. In December, 1900, he was appointed Professor of Anatomy at King's College, and served on a number of boards and committees connected with medical educational work. In 1904 he was elected Professor of Anatomy in Birmingham, and since 1905 has acted as sub-Dean of the Medical Faculty. He delivered the Hunterian Lectures to the Royal College of Surgeons in 1903, on the comparative anatomy of the placenta. Professor Robinson has thus had an unusually large share of experience in organising, teaching, and administration, and his teaching has been attended with uniform success, both as regards increase in the number of students in his various schools, and as regards the raising of the level of anatomical study to a higher standard.

## LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

### THE NEWSPAPERS AND ADVERTISEMENTS.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The following paragraph appears in *Punch* of to-day, August 4th:

"In an action brought by the *Times* to recover the price of an advertisement article, the defendant alleged that the contract was for an advertisement in the form of a leading article. 'That, of course, was out of the question,' stated plaintiff's counsel, 'as no paper would enter into such an agreement.' This clearly proves that legal innocence is not confined to the Bench." Mr. Punch is evidently very well aware that, with the exception of the *Times* and a small percentage of papers that place honour before pelf, every newspaper has its price, and in the majority of cases the price is a low one. The majority of newspapers now accept advertisements well knowing them to be false and fraudulent, and a great number insert them in editorial form. Some time ago the proprietors of a gross fraud in form of a mechanical contrivance for the cure of an incurable surgical disease made an offer by circular letter to all the medical papers for insertion of advertisements in form of editorial articles; and all these papers published and commented upon this impudent procedure. The offer was doubtless made widely among lay papers, many of which printed the puffs in question. The offer to the medical papers was probably made by mistake. The incident was, however, sufficiently significant. It seems a pity that Mr. Punch whose function it is to expose humbug, and shoot folly as it flies, does not get

expert advice as to the quality of some of the advertisements which appear in his own pages, or inquire into the question for himself. The occasional appearance of announcements in the least degree questionable in *Punch*, forms a justification for his less scrupulous contemporaries in "going one very much worse." If Mr. *Punch* wishes for enlightenment on this subject he can find it in the pages of recent volumes of the MEDICAL PRESS, or in the Report of the Australian Royal Commission on Quackery; and as this Report is not easily to be obtained in this country, I shall be glad to lend him mine to study at his convenience.

I am, Sir, yours truly,

HENRY SEWILL.

The Old Rosery, Redhill,  
August 4th.

#### THE NORMYL TREATMENT OF ALCOHOLISM. *To the Editor of THE MEDICAL PRESS AND CIRCULAR.*

SIR,—By the courtesy of some anonymous friend, I yesterday received a copy of "Medical Temperance Reformer's" letter which appeared in your issue of July 28th. It proves that your correspondent is a man of leisure and fond of writing superfluous letters, which is certainly not the case with my 150 medical customers nor myself. Why should he not undertake the scientific inquiry which he advocates? There is nothing to hinder him, and he will find at the office of the Normyl Association plenty of material to work upon. There is nothing so cocksure and nobody so deluded as a scientist without experience, and no one more humble than a truly scientific person who has learnt and is ever learning in the school of actual fact. It is a matter of no importance whatever that your correspondent is uncomplimentary, or that, in parrot-like fashion, he says, "The whole thing is a delusion." Your readers who care about the truth and the actual saving of alcoholic victims can judge for themselves by inquiry and examination. The Normyl treatment is by no means ignored, but is constantly and increasingly used by truly scientific persons, and the annual rescue of something like a thousand persons from misery affords plenty of consolation to me for the occasional jeers of a merely nominal reformer.

I am, Sir, yours truly,

CECIL CHAPMAN.

#### THE QUACK MEDICINE TRADE.

*To the Editor of THE MEDICAL PRESS AND CIRCULAR.*

SIR,—Every practitioner of much experience can testify from personal knowledge to the truth of the indictment of the traffic in quack medicines formulated in the course of the admirable paper on Medical Journalism by Dr. David Walsh in your current issue. The description fraudulent, cruel, and murderous applied to the trade repeatedly by Mr. Henry Sewill is entirely accurate; and I agree with him that on humanitarian grounds alone it is the duty of our profession to force the facts upon the attention of statesmen, and put upon them the responsibility for the continuance of a system which is inflicting such injury upon the poor and ignorant classes. I am making note of cases in the courts in which the worst evils of quackery are exposed, and if others will do the same throughout the country the evidence available for a Royal Commission, or for embodiment in a demand for a Commission, can easily be made irresistible. Here are three recent cases. A child died without medical attendance. The medical evidence at the inquest proved the death due to double pneumonia. The parents, questioned by the Coroner, stated that they had relied throughout upon a "lung healing" medicine advertised in the local papers. A man died without medical attendance. At the inquest it was proved that, disregarding the advice of his doctor, he had relied upon a cure for diabetes warranted successful "without other medicine or change of diet." A man died from dropsy due to kidney disease. He had not been medically attended, but had pinned his faith on a much advertised kidney cure. It is significant that although in each of these three cases the names of the quack medicines were repeatedly mentioned in court, they were not given in the newspaper reports; and the local papers continue to publish puffs of these frauds in the

form of editorial paragraphs. The case before Mr. Justice Lawrence at the Sussex Assizes, two years ago, shows that the law is now sufficient to reach a great section of quack medicine vendors, but there exists no authority with powers and obligation to put it in force. Heavy penalties can be inflicted upon food adulterators, or upon violators of the Merchandise Marks Acts, fine or imprisonment for falsely labelling cigars or brandy; but it is at present impossible to punish the criminals who, by means of persistent lying advertisements, induce wretched sufferers from organic and malignant disease amenable to scientific treatment, to rely upon nostrums the complete worthlessness of which can be demonstrated even to those who have no scientific knowledge whatever.

I am, Sir, yours truly,

August 2nd. AN OBSCURE PRACTITIONER.

#### CONJUNCTIVITIS NEONATORUM.

*To the Editor of THE MEDICAL PRESS AND CIRCULAR.*

SIR,—You published in your journal for April 1st, 1908, an editorial under the above heading, in which you condemned the use of the term "ophthalmia" as applied to the conjunctival inflammation of infants, pointing out that the term was obsolete, inaccurate, and unscientific. Despite, however, this expression of opinion, I notice in your issue for this week a leading article, entitled "Ophthalmia Neonatorum." It would be interesting, no doubt, to your readers to learn from you the method by which the inconsistency of this policy could be justified.

I am, Sir, yours truly,

July 30th, 1909. ANOTHER OBSCURE PRACTITIONER.

#### THE DECLINING BIRTH-RATE.

*To the Editor of THE MEDICAL PRESS AND CIRCULAR.*

SIR,—I am glad to see your able article on the above subject. It is of tremendous importance to the State, and of extreme interest to the physician and to the sociologist. On several occasions you have allowed me to enter into the discussions that have taken place in your columns. I have always held that a declining birth-rate due to the causes which have brought it about in France is a sign of national decay. It will lead to the conquest or subjection of the decaying races by more virile stocks; and if the decay is to affect fully all the western nations it will probably terminate in realisation of the "yellow peril"—the dominion of the world by the Japanese and Chinese. The declining rate is not due to loss of fertility; it is brought about solely by the deliberate action of married people. Their motive is a narrow form of anti-social and anti-patriotic egoism. The parents look upon toil and self-sacrifice as evils to be shunned; their ideal is idleness and luxury; and they want to avoid for themselves and their few children the necessity of entering into a vigorous battle of life. The population of France is far below her home requirements; she has no prospect of being able to people the vast overseas territories—the highlands of Madagascar, for instance—where there is room in suitable climates for many millions of inhabitants of European blood. Every Frenchman has been for many years fully aware that the increase in the German population would in a short time place their country at the mercy of their mighty neighbour, and, whilst constantly proclaiming their lofty patriotism, the French have universally refused to do the only thing possible to put their nation in a position of honourable security. Instead of this, they subsidised at a stupendous cost the Russian Government to act as their ally—a government which personified every one of the evils against which Frenchmen are never tired of declaiming. The humiliating position in which France has deliberately placed herself is only one of the many big symptoms of her moral decay. In spite of the fact that she has produced a Pasteur and other commanding intellects during the past century, it would be easy to describe a great number of other symptoms pointing to decline in all the powers that go to sustain the greatness of a people. French wealth has rapidly accumulated, whilst Frenchmen have, with equal swiftness, decayed.

I am, Sir, yours truly,

August 4th. A STUDENT OF SOCIOLOGY.

## OBITUARY.

**WILLIAM ARTHUR FOXWELL, M.A.,  
M.D.Cantab., B.A.Lond., M.Sc.Birm., F.R.C.P.**

WE regret to record the death of Dr. William Arthur Foxwell, who recently met with an accident whilst cycling. He was riding along the outskirts of Warwick, when he was upset by a dog which ran out of a side street and dashed into the machine. Dr. Foxwell fell on his head and sustained injuries to the base of the skull and spine. He was picked up unconscious, and was removed to the Warneford Hospital, Leamington, where he lay until his death.

Dr. Foxwell was born at Shepton Mallet in 1853, and had therefore but recently completed his 56th year. His early education was obtained at Queen's College, Taunton, whence he passed to St. John's College, Cambridge, where he graduated as M.A. and M.D., taking a distinguished place in the Natural Sciences Tripos and in the medical examinations. He followed up his medical studies at St. Thomas's Hospital, London, and the General Hospital, Vienna. In 1873 he added to his other distinctions that of B.A. (London University), with honours in English and Moral Science. He became a Fellow of the Royal College of Physicians in 1892, and was also an M.Sc. (Birmingham University). His work in Birmingham commenced as pathologist at the General Hospital in 1884, and he was also assistant physician from 1885 to 1889. On the transference of Queen's College to the Birmingham University he became one of the Professors, and presided over the studies of the students in therapeutics. He received from the University its degree of M.Sc. In 1896-98 he was examiner in medicine to Cambridge University.

Dr. Foxwell was the President of the Birmingham Medical Institute, an institution which he also served as honorary librarian from 1887 to 1901, and for two years he was the Editor of the *Birmingham Medical Review*. Amongst other professional honorary posts which he had filled was that of President of the Midland Medical Society. He was recognised as one of the best authorities in the country on the subject of heart disease. He contributed many papers to the medical journals, and also published separately essays on heart and lung diseases, the enlarged cirrhotic liver, the spas of Mid-Wales, and the causation of functional heart murmurs. He joined the staff of the Queen's Hospital in 1889, and last year he was chairman of the medical committees of the institution.

His chief memorial in connection with the hospital, which he served with the utmost devotion, will be his initiation of the roof ward system, now successfully established at the Queen's for the treatment of serious diseases other than those of tuberculous origin.

Outside the institutions and societies connected with his profession, Dr. Foxwell took little part in public life. He was not a man of strong physique, and was obliged to husband his strength as much as possible apart from his work as a physician, in which he never spared himself. His chief recreation was gardening, and his general pursuits in private life were scholarly.

**EDWARD BENJAMIN STEELE-PERKINS, L.S.A.**

WE regret to record the death at Exeter, at the age of 67, of Mr. Edward B. Steele-Perkins, a well-known surgeon of the city, and a member of an old Exeter family. For nearly forty years he was a familiar figure in Exeter, and his geniality won him very many friends. Entering into partnership with his father in 1879, he commenced his career in the city as a medical practitioner, and continued until laid aside by illness three years ago. He was at various times medical officer to the Exeter Oddfellows, to the Conservative Equitable Benefit Society, and was honorary surgeon to the Devon and Exeter Home of Refuge. He was keenly interested in the volunteer force, and for many years held a captaincy in the 1st Devon Artillery Volunteers, retiring about ten years ago with the honorary rank of major. He succeeded to the freemanship of the city by inheritance on the death of his father. For several years he rendered useful service on the Exeter City Council, as a representative in the

Conservative interest of St. Sidwell's Ward, for which he was first elected a member after a keen party contest.

**EDWARD HEPBURN SECCOMBE.**

WE regret to announce the death of Dr. Edward Hepburn Seccombe, who for upwards of 30 years was a well-known medical practitioner in the district of Belgravia. Dr. Seccombe, who was the youngest son of the late Sir Thomas Lawrence Seccombe, G.C.I.E., entered King's College Hospital as a student, and became qualified as a member of the Royal College of Surgeons in 1867, and as a licentiate of the Society of Apothecaries in 1868. In the following year he obtained the M.B. degree of the University of London, and subsequently became an associate of King's College. Dr. Seccombe had been medically connected with the Metropolitan Convalescent Institution, the Royal Pimlico Dispensary, and the Royal India Lunatic Asylum, Ealing.

## MILITARY & NAVAL MEDICAL NOTES.

**INVESTIGATIONS ON TYPHOID CARRIERS.**—It is a pity that Members of Parliament are trying (by asking the Secretary of State for War unnecessary questions in the House about germ carriers) to thwart the Military Medical Authorities in their efforts to do good work. It is in the interests of the soldier, his comrades, and the civil community indirectly that the treatment is being carried out of possible carriers of typhoid infection, and Mr. Haldane is to be congratulated on assuming a firm attitude.

**THE NEW DIRECTOR-GENERAL, ARMY MEDICAL SERVICE.**—Now that Surgeon-General Gubbins, Deputy Director-General, has been appointed the coming Director-General of the Army Medical Service, speculation is rife who is to be the next Deputy Director-General, for that will mean succession in course to the Director-General's chair, as it has been settled that every Deputy Director-General shall succeed to the Director-General's chair. The decision to appoint Dr. Gubbins to the chief post has been received with much satisfaction by the Army Medical Service.

**THE NEW PROFESSOR OF TROPICAL MEDICINE.**—Major W. S. Harrison, R.A.M.C., who has been for many years assistant to Lieut.-Colonel Temple at the Pasteur Institute at Kasanti, has been selected to succeed Lieut.-Colonel R. J. S. Simpson as Professor of Tropical Medicine at the Royal Army Medical College, London. Captain J. C. Kennedy, who did excellent work with the Malta Fever Commission, succeeds Major Harrison as Assistant Professor of Pathology at the College.

**HOSPITAL STOPPAGES FROM NAVY PAY.**—Some time ago we noted the dissatisfaction which existed among the sailors of our Navy in respect of hospital stoppages. A deputation waited on the First Lord of the Admiralty, and pointed out this among other grievances in the naval ranks. Thanks were given to their Lordships for the recent concession of 30 days in respect of hospital stoppages; but hope exists that the full requirements of the men of deducting no stoppages at all will be entertained by the Admiralty.

**THE GERMAN NAVY HEALTH REPORTS** for last year show that the sick rate has increased, being 500 per 1,000, the highest being in East Africa, *i.e.*, 992.8 per 1,000. The average duration of treatments was 18.3 days—on board ship 8.5 days and on shore 9.8 days, but in China at Kiau Chin 15.3. Of recruits 23 per 1,000 of the naval force were discharged chiefly for cardiac diseases. Diseases of the heart and lungs are the most frequent causes of invaliding. The mortality is low, 1.5 per 1,000. Among the causes of deaths, 14 suicides (3 officers) are shown.

**ROYAL ARMY MEDICAL CORPS.**—Colonel A. Peterkin

vacates the post of Administrative Medical Officer at Cape Town, he having been selected for the appointment of P.M.O., London District.—Lieut.-Colonel Sir J. Fayrer, Medical Officer of the Duke of York's School, is to be appointed for duty at Hong Kong.—Lieut.-Colonel M. W. Russell, Medical Inspector of Recruits, Eastern Command, will succeed Lieut.-Colonel C. R. Tyrrell on August 22nd as staff officer to Surgeon-General J. C. Gorman, C.M.G., P.M.O. Eastern Command.

## LABORATORY NOTES.

### MESSRS. BURROUGHS WELLCOME AND CO.

We have been favoured with several samples of Messrs. Burroughs Wellcome and Co.'s new products. A soloid of zinc sulphate should prove extremely useful to all who may be in want of solutions of that drug. Each soloid is made up of such a strength as to furnish, when dissolved in 1 oz. of water, a 1 per cent. solution available for ionic medication. Another useful tabloid has 4.37 grammes of potassium iodide. Another contains a similar quantity of sodium chloride, and is handy for making normal saline solutions.

### IMPORTANT ARYLARSONATES.

STRIKING clinical results have been reported from the use of the arylarsonates introduced by Burroughs Wellcome and Co., under the trade-mark names of "Soamin," "Kharsin," and "Orsudan." In the treatment of syphilis, sleeping sickness, malaria, and other protozoal diseases, the low toxicity of these salts enables physicians to administer comparatively large quantities of arsenic without toxic effects.

"Soamin" (sodium para-aminophenylarsonate) is stable, uniform in action, is soluble in about five parts of water, and gives a neutral solution which can be sterilised. It contains 22.8 per cent. of arsenium in organic combination, and has less than 1.40 the toxicity of arsenious acid. Results of the administration of "Soamin" in cases of syphilis demonstrate the great therapeutic value of this agent. It can be obtained in the form of powder or of tabloid.

"Kharsin" (sodium 3-methyl-4-aminophenylarsonate) is soluble in two-and-a-half times its weight of water, and gives a neutral solution. It contains 23.7 per cent. of arsenium, and is about equal in toxicity to "Soamin."

"Orsudan" (sodium 3-methyl-4-acetylaminophenylarsonate) is anhydrous. It is soluble in three times its weight of water, and gives a neutral solution. It contains 25.4 per cent. of arsenium, and is the least toxic of the three salts, being 1.5 or 1.6 less toxic than "Soamin," and has been found of marked value in malaria. It is sold as powder or tabloid.

It need hardly be added that the arylarsonate salts should not be given by the mouth, as they are broken up by the acid contents of the stomach, and the effects of over-treatment by arsenic are thus more easily produced. Freshly prepared solutions should be administered by subcutaneous or intra-muscular injection, preferably the latter. "Soamin," again, should not be used simultaneously with mercury, nor administered until fifteen days after mercurial treatment has ceased.

### PARKE, DAVIS AND CO.

We have been favoured by Messrs. Parke, Davis and Co. with samples of the following novelties:—

#### ADRENALIN TABLETS No. 2.

Each of these tablets contains 1/200 grain of adrenalin, and is therefore of the same therapeutic value as 5 minims of the 1/1,000 solution. They are put up in tubes of 25 tablets, a form which is not only convenient for carrying, but also preserves the properties of the drug. For obtaining a prompt physiological effect, one or more of the tablets, as may be required, may be placed under the patient's tongue, whence the drug is rapidly absorbed, or may be dissolved in sterile water and administered hypodermically or intravenously. The tablets are also useful for adding to solutions of cocaine or other analgesic for topical or subcutaneous administration to avoid pain and bleeding in minor surgical operations.

### ADRENALIN AND NOVOCAINE TABLETS.

These tablets are supplied in two strengths. No. 187, dissolved in 15 minims of water, forms a 2 per cent. solution of novocaine with 1 of adrenalin in 3,000; No. 188, in the same quantity of water, forms a 1 per cent. solution of novocaine with 1 of adrenalin in 6,000. Experience proves that stock solutions of adrenalin and novocaine are not so efficient as those made at the moment of use. These tablets, therefore, are not only convenient (they are most readily soluble), but offer the best means of employing novocaine, which is said to be the equal of cocaine in anæsthetic power and less toxic, in association with the ischæmic properties of adrenalin in surgical operations.

### ADRENALIN AND CHLORETONE SUPPOSITORIES.

Each suppository contains 3/200 grain of adrenalin (equivalent to 1 in 1,000), and 3 grains of chloretone in a cacao-butter base, and affords a reliable means of obtaining constringent, analgesic, and antiseptic effects in rectal disorders, such as hæmorrhoids, pruritus, ulceration, etc.

### ADRENALIN COMPOUND SUPPOSITORIES.

Each contains 1/100 grain of adrenalin, 3 grains of formidine, 1/2 grain of cocaine hydrochloride, and 3 grains of extract of hamamelis. Formidine is a condensation product of iodine, formaldehyde, and salicylic acid, and is an effectual germicide, and is said to be superior to iodoform in that it is free from noxious odour. In analgesic power these suppositories are superior to the preceding, and they also include the valuable tonic astringent influence of hamamelis. They are employed in the same class of disorders as specified for the foregoing, and are supplied in boxes of one dozen.

### MERCURETTES.

Mercurettes are oblong blocks (cleanly and convenient), in which metallic mercury is most intimately incorporated with cacao-butter, and agreeably perfumed. Each block contains the amount of mercury present in 1 drachm of the pharmacopœial ointment, though in a somewhat greater dilution, which lessens danger of irritation to the cuticle. Any quantity that it may be required to use can easily be apportioned by cutting the block. They are primarily intended for the inunction treatment of syphilis, for which purpose cacao-butter provides an agreeable vehicle for the mercury, in every way preferable to the lard and suet basis of the B.P. ointment. But they may also be used for any condition in which the external application of mercury is indicated. Though of firm consistency, vigorous friction quickly causes the mercurette to penetrate the skin. Mercurettes are supplied in boxes of six.

### PITUITRIN.

Pituitrin is an extract of the infundibular portion of the pituitary gland. It exerts a vaso-motor constrictor action very similar to that of adrenalin, but somewhat more prolonged, and an influence on the circulatory system similar to that of digitalis and strophanthus. It very considerably increases the urinary flow. Pituitrin may be given either orally or hypodermically in doses of from 10 to 30 minims four times daily. It is supplied in bottles of 1 oz.

### BAYER CO.'S PRODUCTS.

We have received from the Bayer Company various samples, which we have pleasure in introducing to the notice of readers. Thyresol, a methyl ether of santalol, intended for the internal treatment of gonorrhœa. It is chiefly remarkable in that, while it is claimed to have powerful antiseptic properties quite equal to those of santalol, the latter body is not liberated in the system. Thyresol contains no free hydroxyl groups, and is relatively non-toxic. Mainly for these reasons it obviates such unpleasant by-effects so frequently associated with sandalwood oil medication, as excitation, irritation of the stomach, loss of appetite.

The dose of Thyresol is 5-10 grains three or four

times a day, and may be taken in drops, capsules or tablets. A feature of the last-named is the magnesia carbonate forming their base—the combination exerting a distinct laxative effect—an obvious advantage in gonorrhoea.

## NEW INSTRUMENTS.

### A COMBINED CATARACT SPOON AND SPATULA.

By H. H. B. CUNNINGHAM, M.D., F.R.C.S.I.,  
M.R.C.S.Eng.,

Assistant Surgeon, Belfast Ophthalmic Hospital; Examiner in  
Ophthalmology, Royal College of Surgeons, Ireland.

IN performing the operation of cataract extraction, and more especially when it takes place in a private house, the surgeon is not always provided with the number of assistants and of appliances that are to be

found in a modern well-equipped hospital, therefore the less the actual number of instruments the better for the operator. With this aim in view, the instrument shown in the accompanying drawing has been designed. It consists simply of an ivory handle, into one end of which is inserted a tortoiseshell spatula and into the other a tortoiseshell spoon. The handle is made of ivory on account of its light weight, and also because with this instrument it is easy to estimate the amount of pressure that is being exerted on the eye when in use. The makers are Messrs. Down Bros., London.

## MEDICAL NEWS IN BRIEF

### Action for Negligence.

DURING the recent Belfast Assizes the Hon. Mr. Justice Dodd heard the action brought by John Beattie, smith's finisher, 33 Lomond Avenue, against Dr. John S. Bryars, 239 Mountpottinger Road, and Dr. Charles A. Mateer, Kimberley Gardens, Bloomfield, to recover £1,000 damages for personal injuries alleged to have been caused by the negligence and want of skill of the defendants. Mary Beattie, wife of the plaintiff, deposed that previous to the accident her husband was a strong, healthy man. When he was brought home after the occurrence he was in great pain, and Dr. Bryars, the society doctor, was sent for. She stated that Dr. Bryars said her husband was struck on the sciatic nerve, and described the treatment given. Dr. Mateer was subsequently called in, and the treatment was continued. Eventually the plaintiff went to the hospital, and had an X-ray photograph taken of the limb by Mr. Rankin, but Dr. Mateer did not tell her what the photo showed. In January her husband was examined at the hospital by Surgeon Campbell, who gave him medicine to strike fluid out of the bone. Surgeon Campbell said he was full of rheumatics. In February plaintiff went to see Dr. Allworthy, who told him that the neck of the thigh bone was broken, and, as a result, he was taken to Surgeon Kirk and operated upon in the Royal Hospital, where he was a patient for nine weeks. At the present time her husband's leg was almost three inches short.

Cross-examined by Mr. Chambers, K.C.—She did not complain of Dr. Bryars being inattentive, but she thought he did not examine her husband sufficiently. Dr. Mateer made a thorough examination of the limb. Dr. Wadsworth, who had examined her husband, said he had got a very bad knock on the thigh bone.

By Mr. Macaffree.—Dr. Mateer did not advise that another doctor should be called in, and that an X-ray photograph of the limb should be taken. Dr. Mateer had attended witness and her children for years, and always gave satisfaction.

Dr. Samuel W. Allworthy, Antrim Road, deposed that Beattie came to him to be treated for sciatica, and after examination witness came to the conclusion that he was suffering from a fracture of the thigh bone.

Dr. John S. Bryars was then called, and, examined by Mr. Hanna, described his diagnosis of the case, from which he came to the conclusion that the plaintiff was suffering from a bruise on the hip.

His Lordship: And not a fracture?—No, my lord. Independently of witness, Dr. Mateer agreed that the injury was a contusion of the hip. Witness described his treatment of the case. He would not, he thought, have certified that the man was suffering from sciatica, but would have stated that the injury was due to a contusion of the hip. He treated the plaintiff to the best of his skill and knowledge.

By Mr. Thompson.—Anyone might have mistaken the fracture for a contusion of the hip, and all that he saw throughout the case was consistent with the diagnosis.

Dr. Charles A. Mateer was also examined at considerable length.

Dr. Robert Campbell, a specialist in fractures, stated, in reply to Mr. Hanna, that he came to the conclusion that the man was suffering from a rare kind of fracture, in which the bone was fractured, but the outer membrane was unbroken. That was an exceedingly difficult fracture to diagnose.

Surgeon Kirk deposed to operating on the plaintiff in March last. The form of operation was one that was not taught in his student days, and to his surprise and horror he found that the place where he thought the break had been moved with the shaft perfectly well. On searching very carefully he detected a very rare form of fracture, which could not have been produced in the ordinary way. The treatment of Dr. Bryars and Dr. Mateer did not tend to prevent union. He believed the plaintiff would be fit for work after the operation.

Counsel on both sides having spoken, his Lordship summed up, and the jury, after a long absence, returned to court with a verdict for the defendants.

### Death Under Chloroform.

AT Southwark, Dr. F. J. Waldo conducted an inquiry with reference to the death of Phoebe Chart, aged 44, which occurred in Guy's Hospital while under the influence of chloroform.

Dr. Vincent Townrow said that the deceased woman was admitted on July 25th for an operation for cancer. Two days later she was placed under chloroform, and in the course of a few minutes she stopped breathing. Ether was injected into the heart, and through an incision made in the abdomen the surgeon massaged the heart, but there was no response.

Replying to the coroner, the witness said that only a competent medical man could have adopted these measures. A dentist could not resort to such a means of restoring animation. Witness added that death was due to heart failure due to the action of the anæsthetic on the cardiac muscles.

Dr. Francis Shipway, honorary visiting anæsthetist, said he gave the patient chloroform because she was stout, and ether would have been unsuitable. Chloroform was five times more dangerous than ether.

The coroner said that of forty-one cases of deaths under anæsthetics brought under his notice, thirty-three were due to chloroform. He observed that many of the deaths occurred before the operations were commenced.

The jury returned a verdict of accidental death, and added that every care had been taken at the hospital.

### Operation in Mid-Atlantic.

ON the recent arrival of the Cunard liner, *Mauretania*, it became known that an operation for appendicitis had been carried out on board during rough weather. A man employed in the stokehold, named Robert Gibbons, was taken ill suddenly, but did not discontinue his work until internal pains actually prevented him from passing forward the coal for the furnace. The ship's surgeon, Dr. Jones, was then called in, and found the man suffering from a dangerous attack of

appendicitis. Two eminent New York surgeons, Dr. W. B. James and Dr. F. T. Kinnicutt, chanced to be aboard, and Dr. Jones called them into consultation. They determined to operate at once, though the ship was pitching considerably in spite of her size under the violence of the sea. It was discovered that Gibbons had allowed his ailment to go too far before treatment, and the operation was therefore too late.

#### Prevention of Blindness.

AT Stoke-on-Trent, on July 28th, a meeting of representatives of local authorities, medical officers of health, and others was held, for the purpose of considering the best means of averting infantile ophthalmia. The Earl of Harrowby, chairman of the Sanitary Committee of the County Council, presided. Lord Harrowby explained the object of the meeting, and said that the question was one which had interested him to a great extent, more particularly as chairman of the Sanitary Committee of the County Council. They in the Potteries had taken the initiative in the prevention of infantile blindness. Of course, they could have wished that the question should be discussed throughout the county, but they were glad to find that in North Staffordshire they had taken the lead, and he hoped the result of their deliberations would be productive of great good. They could not fail to express their thanks to Mr. Greatbatch for having taken up that very important question. There were eighty-six blind children being educated in the county, and it was a very startling fact that of that number thirty-four would never have been blind if they had received proper attention immediately after birth. They were also told by the leading authorities that no less than 40 per cent. of the blind children of the country could have been cured if they had been properly treated a few days after birth. In view of the cost of educating the blind, it followed that at least £15,000 was lost annually in educating the thirty-four blind children in Staffordshire who might have been cured.

Dr. G. Reid proposed the following resolution: "That, in the opinion of this meeting of the Mayors, chairmen of Urban District Councils, and medical officers of health of the northern division of the county, the adoption by public health authorities of the Notification of Births Act (1907) is desirable. And this meeting is further of opinion that the disease known as ophthalmia neonatorum that is, inflammation of the eyes in new-born children, up to ten days old—should be added to the list of diseases compulsorily notifiable under the powers of the Infectious Diseases (Notification) Act, 1889."

#### High Peak Hospital and Diphtheria.

AT a meeting of the governors of the High Peak Hospital it was reported by the medical superintendent that without any previous notification to the authorities a patient from the New Mills district suffering from diphtheria had been brought to the hospital in an open conveyance, with a note from the medical man in attendance, who, resides in another district, asking that the case be admitted, as it was of an urgent nature. Miss Rowbottom, the head nurse, on going to the gates found that the patient was practically dying in the conveyance. Death took place several hours later.

The medical superintendent drew the attention of the governors to the fact that several cases of diphtheria had been sent to the hospital lately in a moribund condition, and pointed out the uselessness of conveying patients to the hospital under such circumstances.

In the course of discussion it was stated that the regulations had not been complied with, as the authority of the medical officer of the New Mills district ought to have been obtained, when the hospital ambulance would have been sent for the patient.

#### Sale of Poisons in Ireland.

THE Statutory rules approved by the Privy Council in Ireland in connection with the working of the Poisons and Pharmacy Act of last year have been laid on the table of the House of Commons. The following are the chief provisions of the regulations:—

A licence shall not be granted to any person unless the local authority are satisfied that he is fit by education and intelligence to be entrusted with the sale of poisonous substances, and has made suitable provision for the separate storage of the same in a distinct and separate part of his shop or building where he proposes to sell the same. In granting licences for the sale of poisonous substances for use exclusively in horticulture, preference shall be given to nurserymen, florists, seedsmen, and other persons, whose business is specially connected with horticulture. No licence for the sale of poisonous substances shall be granted to any person who is illiterate, or who is under the age of 21 years. All poisonous substances shall be kept by the licensee in a separate drawer, or cupboard, or closed receptacle, apart from other goods, and poisonous substances shall not be sold upon the same premises as articles of food for human consumption, unless the local authority are satisfied that convenient arrangements for their sale cannot otherwise be made, and in that case they must be sold at a separate counter. For the purpose of this regulation, a part of a counter which is shown to the satisfaction of the local authority to be adequately separated from the rest of the counter shall be treated as a separate counter.

A poisonous substance shall not be sold except in an enclosed vessel or receptacle, as received from the manufacturer, distinctly labelled with the word "poison," the name of the substance, the name and address of the seller, and the notice of the special purpose for which it has been prepared. Liquid preparations shall be sold only in bottles or tins, as received from the manufacturer, and such bottles and tins shall be so constructed as to bear the ordinary risk of transit without leakage, and to be easily distinguishable by touch from ordinary bottles or tins, and the word "poison" or "poisonous" shall be indelibly marked on each bottle or tin. Solid preparations shall be securely packed, and the package shall contain a notice that it must be destroyed when empty.

#### A Threatening Letter.

AT the Dublin Commission, before Mr. Justice Dodd, John Brownlow was indicted for having sent a threatening letter to Dr. W. R. Dawson, last July. The prisoner, who pleaded guilty, had been in the employment of Dr. Dawson, but his engagement having terminated, he declared he had become depressed. Dr. Dawson gave Brownlow an excellent character, and having entered into bail for his good behaviour for two years, the man was liberated.

#### One Medical Officer to 160 Patients.

AT Fulham Infirmary a lunatic was put in the padded room, and next day he was found there dead. At the inquest the medical superintendent said the night porter left a note for him asking him to see the patient, but he did not get it. His staff was not large enough for a doctor to take night duty. There was one doctor to 160 patients, and a large workhouse, with 780 inmates, to look after as well. In finding that death was due to syncope from delirium tremens, the jury recommended that every case admitted should be seen by a doctor immediately.

#### Slaughter-Houses.

THE following Memorial has been presented by the Humanitarian League to the Right Hon. John Burns, M.P., President of the Local Government Board:—

SIR,—In view of the fact that it is over four years since the Committee appointed by the Admiralty to consider the Humane Slaughtering of Animals reported strongly in favour of replacing private slaughter-houses by public abattoirs; that the same course was advocated in the Report of the Royal Commission on Tuberculosis in 1896, and has been urgently recommended by the Public Health Committee of the London County Council and by a number of leading medical and sanitary authorities; and that London is in this respect far behind the great majority of continental cities, and not a few provincial ones, such as Glasgow and Edinburgh; we desire to appeal to you to take

the necessary steps to give effect, in the Metropolitan district, to this much-needed but long-delayed reform.

Among the signatories are the following eminent members of the medical profession:—

Sir James Crichton-Browne, M.D., D.Sc., LL.D., F.R.S.

Sir Thomas Barlow, Bart., M.D., D.Sc., F.R.C.P., etc.

Sir Samuel Wilks, Bart., M.D., LL.D., F.R.S., etc. (Consulting Physician to Guy's Hospital).

Sir Jonathan Hutchinson, F.R.S., F.R.C.S.

J. Mitchell Bruce, Esq., M.A., LL.D., M.D., F.R.C.P.

James Cantlie, Esq., M.B., F.R.C.S.

Alex. Hill, Esq., M.A., M.D., F.R.C.S., J.P.

Alex. Haig, Esq., M.A., M.D.

Sir Arthur Conan Doyle, M.D.

The Medical Officers of Health for Bermondsey, Deptford, Fulham, Greenwich, Hackney, Hampstead, Holborn, Islington, Lambeth, St. Marylebone, Shore-ditch, Southwark, Stepney, Stoke Newington, and Woolwich.

#### Hospital Entertaining Expenses.

In May last the Executive Committee of King Edward's Hospital Fund appointed a sub-committee to consider and report as to what action, if any, it might be advisable for the Fund to take in reference to the question of the expenses of charity entertainments.

Lord Richard Cavendish was elected chairman, the other members being Mr. J. G. Griffiths and Mr. A. E. Sydney, with Mr. F. M. Fry. Five meetings were held by the committee, and a great deal of written and oral information was submitted to them.

In considering the evidence the committee kept in mind the following questions:—(1) Are entertainments a valuable method of raising money for a hospital? (2) Is there at present any widespread tendency to extravagance or abuse in connection with this means of raising money? (3) In what way can the hospitals best guard themselves and the public against the danger of waste or abuse without depriving themselves of a source of income?

Upon the first question the committee report that there can be no doubt that the practice of charity entertainments for hospitals has established itself as one of the recognised methods of raising funds, and that they have been found to be a means of securing income which could not be obtained in any other way.

Upon the second question they are glad to be able to report that the evidence before them points to the conclusion that neither extravagance nor abuse prevails to any large or general extent. They came, however, upon isolated instances which indicated the existence of certain dangers in this direction, and they make a number of suggestions by which this can be avoided. If the hospital itself is responsible for the management of the entertainment, the probable relation of the expenses to the receipts needs to be carefully considered, and the committee emphasise the necessity of forming detailed estimates beforehand. Mention is made of a rule which is in force in some hospitals, that permission to use the name of the institution is only granted where the governing body has a voice in the management of the entertainment, and the stipulation that all accounts for expenses should be paid by the hospital secretary or that all cheques should be countersigned by a representative of the hospital.

They mention, however, some classes of expenditure which may in some cases have to be specially considered when estimates are being formed or accounts are being examined. The cost of the services of professional artists is one of these. The extent to which members of the dramatic, musical, and kindred professions give their time and skill gratuitously and ungrudgingly to the assistance of charity is a matter of common knowledge. But, at the same time, it is occasionally necessary for hospital committees to see that the deservedly high reputation of the professions in this respect is not used by less scrupulous or less public spirited persons as a cloak for individual profit, and that no undue proportion of the money intended

for the benefit of the hospital goes in "travelling" or other "expenses" attributed to artists. In the case of balls, where refreshments are necessarily included in the price of tickets, the giving of complimentary tickets should be carefully controlled.

#### The University of Liverpool.—The William Mitchell Banks Memorial Lecture.

THE fifth William Mitchell Banks Memorial Lecture was delivered in the University of Liverpool by Dr. Harvey Cushing, of the Johns Hopkins University, on Wednesday, August 4th, the Lecturer taking as his subject, "Recent Observations on the Pathology and Surgical Treatment of Intracranial Tumour." He referred in particular to the results of palliative and radical operations performed during the previous ten months on sixty-four cases. He detailed first the symptomatology of the affection, and drew particular attention to the alterations in the fields of vision and of colour vision as among the earliest observable phenomena. In dealing with the morbid anatomy, he went into detail regarding the experimental work which had been done to demonstrate the functions of the pituitary body, and showed how over-action was associated with the phenomena termed acromegaly and under-action with a characteristic form of obesity and sexual infantilism. He described a case of removal of the pituitary body from an acromegalic. In the third place he demonstrated, by numerous lantern illustrations, the methods of operative technique which were employed in his clinic. The lecture was closely followed and much appreciated by a numerous attendance of medical men and students, and at the close their thanks were accorded to the lecturer by Dr. Monsarrat, the Dean of the Medical Faculty, who presided.

#### Anæsthetic and Death.

WATKIN RICHARDS (32), of Pentrebach, Merthyr, died suddenly whilst an anæsthetic was being administered. On February 5th, whilst working in Hill's Plymouth Colliery, he sustained an injury to his thumb. Mortification subsequently set in, and, after a consultation with his medical attendant, it was decided that an operation should be performed. Dr. Pryce and his assistant, Dr. Twobig, went to deceased's house with the object of performing the operation, and deceased, whilst an anæsthetic was being administered made some remarks and died suddenly.

#### Royal College of Surgeons in Ireland.

THE following candidate has passed the Primary part of the Fellowship Examination, J. B. Dordi, L.M. and S., Bombay Univ., and the following candidates having passed the Final part of the Fellowship Examination were admitted Fellows: J. Gordon, L.R.C.S.I.; L. S. Machado, L.R.C.S., Edin.; T. Murphy, B.Ch., Melbourne Univ.; and F. Spicer, M.R.C.S., Eng.

#### Indian Medical Service.

OF forty-eight candidates who underwent examination on Saturday last for 21 Commissions in the Indian Medical Service, the following were successful. These will be appointed lieutenants on probation in the service. The highest possible number of marks obtainable was 5,100:—

C. H. Smith, 3,997 marks; A. M. Dick, 3,840; T. J. C. Evans, 3,733; R. J. Binning, 3,712; M. J. Holgate, 3,512; J. McD. Eckstein, 3,503; T. L. Bomford, 3,471; W. A. M. Jack, 3,433; G. R. Lynn, 3,412; L. H. L. Mackenzie, 3,404; A. C. Anderson, 3,385; D. G. Cooper, 3,366; W. L. Forsyth, 3,333; K. S. Thakur, 3,288 (Punjab); M. A. Rahmar, 3,281 (Bombay); F. J. Kolaporewalla, 3,258 (Poona); H. R. B. Gibson, 3,257; D. Arthur, 3,252; E. H. V. Hodge, 3,225; G. T. Burke, 3,187; R. H. Bharucha, 3,143 (Bombay).

#### Apothecaries' Hall of Ireland.

THE following have passed the Quarterly Examinations:—1st Professional.—Simon Carroll, Joseph A. Moloney. 2nd Professional.—George M. Mayberry. Final professional.—Edward Murphy, James Stuart.

## NOTICES TO CORRESPONDENTS, &c.

Correspondents requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

### SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12. Messrs. Dawson and Sons are our special agents for Canada.

### ADVERTISEMENTS.

For ONE INSERTION:—Whole Page, £5; Half Page, £3 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d.

The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 52 insertions at £3, and pro rata for smaller spaces.

Small announcements of Practices, Assistantcies, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

ORIGINAL ARTICLES OR LETTERS intended for publication should be written on one side of the paper only and must be authenticated with the name and address of the writer, not necessarily for publication but as evidence of identity.

CONTRIBUTORS are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland to the Dublin office, in order to save time in reforwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

ANESTHETICS.—It seems to us to be impracticable to shut dentists out. One cannot suppose that the Legislature would pass a Bill making it illegal for registered dentists to give gas. The ideal, of course, is that no one not fully qualified medically should do so, but public opinion is not yet ripe for that proposal. The number of deaths from nitrous oxide is very small but there are no statistics available to show the percentage for private practice.

YORKSHIRE.—We know the work to which you refer in the French language only, no English translation has come under our notice. Messrs. Baillière, Tindall & Cox having connections in Paris could probably satisfy on the point.

### A "RESURRECTION" STORY.

In connection with the statement made by Professor Pepper before the Departmental Committee on Coroners' Inquests that "nearly all the cases of reported live burial were myths," the *Daily News* relates a story which it believes to be perfectly authentic, and may be new to our readers. It is the story of a clergyman's wife in the County Cork, who was buried as dead many years ago. The night after the funeral a thief, who was aware that the lady was buried with a valuable ring on her finger, opened the grave, broke the coffin, and endeavoured to remove the coveted ring. Being unable to secure the ring otherwise, the ghoul drew a knife and cut the finger. Instantly blood flowed from the wound, and the lady, who had been in a trance, rose in the coffin, the man running away as one demented. Then the lady walked to her husband's house, where she was received with equal amazement and delight. She recovered completely.

H. S.—You are quite right to ask for a fee under the circumstances, but it is bad policy with an office of good standing to do so before giving a report. You can safely trust them. Send a detailed and conscientious report with your opinion and they will be only too glad to pay you a guinea.

M.B. CANTAB.—Yes, you have a right to call yourself "Dr." everywhere except in the precincts of the University. This is part of the University statutes and was passed when an examination for the degree of M.B. was instituted. The condition holds good for no other University, but there is no reason why you should not avail yourself of the right. If Cambridge M.B.'s do not customarily call themselves "Dr." their ancient right will fall into desuetude.

MR. WINTON.—The one is a natural corollary of the other and should follow in due course.

### A QUESTION IN COMPARATIVE PATHOLOGY.

A CORRESPONDENT has sent us the following query. Can any of our readers throw any light upon the subject?

SIR.—Being in a part of the country which is over run with rabbits, I have been helping my young nephews in their efforts to keep down these troublesome little animals. A fair proportion of the young rabbits have been condemned at sight by the cook—a woman experienced in country lore. In proof of her diagnosis she deftly excised the liver in all cases, and showed an organ studded with pearly white, firm nodules, like early tubercle. The creatures were more or less wasted, according to the stage of the disease. I am told that wet is a predisposing factor. Can anyone tell me what this malady is likely to be, and whether the country people are right in rejecting such animals for food.

I am, Sir, yours truly,

URBS IN RUPE.

August 6th, 1909.

DR. L. (Liverpool).—Your communication to hand while "at press" will be referred to in our next.

DR. A. E. G. (Manchester).—It would have been wiser to send in the notice at the earliest moment, but probably nothing further will be heard of the matter, now that an explanation has been given.

## Appointments.

BRIIGGS, WALTER, M.B., B.S.Lond., M.B., Ch.B.Vict., Honorary Assistant Surgeon to the Blackburn and East Lancashire Infirmary.

CLARK, HILDA, M.B., B.S.Lond., House Surgeon at the Maternity Hospital, Birmingham.

CLARKE, J. MICHELL, M.D.Cantab., F.R.C.P.Lond., pro-Vice-Chancellor of the University of Bristol.

GRAY, L., M.R.C.S., L.R.C.P.Lond., Certifying Surgeon under the Factory and Workshop Act at Stafford.

HICKS, J. A. BRAXTON, M.B., B.S.Lond., Pathologist to the Seamen's Hospital (Dreadnought), Greenwich, S.E.

MONTGOMERY, E. C., M.R.C.S., L.R.C.P.Lond., Certifying Surgeon under the Factory and Workshop Act for the Maidenhead District of the county of Berks.

ORMEROD, J. A., M.D.Oxon., F.R.C.P.Lond., Registrar of the Royal College of Physicians of London.

ROBINSON, ARTHUR, M.D., C.M.Edin., Professor of Anatomy in the University of Edinburgh.

SCOTT, DAVID HART, L.R.C.P. and S.Edin., L.F.P.S., L.M.Glasg., District Medical Officer by the Tiverton (Devon) Board of Guardians.

STALKER, WILLIAM STEWART, M.B., Ch.B.Glasg., Assistant Medical Inspector of School Children by the Wiltshire Education Authority.

SUTTON, HENRY MARTIN, L.R.C.P.Lond., M.R.C.S., L.S.A., District and Workhouse Medical Officer by the Truro (Cornwall) Board of Guardians.

WALTER, E. C., M.R.C.S., L.R.C.P.Lond., Certifying Surgeon under the Factory and Workshop Act for the Wallingford District of the county of Berks.

## Vacancies.

Whitehaven and West Cumberland Infirmary.—Resident House Surgeon. Salary £120, with board and lodging. Applications to Wm. H. Sands, Secretary, Whitehaven.

Borough of Colchester.—Urban District.—Medical Officer of Health and Public Analyst. Salary £550 per annum. Applications to H. C. Wanklyn, Town Clerk, Town Hall.

Hamlet of Mile End Old Town.—Assistant Medical Officer. Salary £150 per annum, with board, lodging, and washing. Applications to Benjamin Catmur, Clerk to the Guardians, Guardians Offices, Bancroft Road, Mile End, E.

Borough of Leigh.—Medical Officer of Health. Salary £400 per annum. Applications to Stanley Wilson, Town Clerk, Town Hall, Leigh, Lancs.

University of Birmingham (Faculty of Medicine).—Professor of Anatomy. Salary £800 per annum. Applications to Geo. H. Morley, Secretary.

Nottingham General Dispensary (Branch).—Assistant Resident Surgeon. Salary £160 per annum, with apartments, attendance, light and fuel. Applications to C. Cheesman, Secretary, 12, Low Pavement, Nottingham.

Manchester Hospital for Consumption and Diseases of the Throat and Chest.—Assistant Medical Officer. Salary £100 per annum, with board, apartments, and laundry. Applications to C. W. Hunt, Secretary, Hardman Street, Deansgate, Manchester.

Southwark Union, London.—Assistant Medical Officer at their Infirmary, East Dulwich Grove, S.E. Salary £100 per annum, with board, lodging, and washing. Applications to Sydney Wood, Clerk, Union Offices, John Street West, Blackfriars, S.E.

## Births.

CLAPHAM.—On Aug 4th, at 10, Carlisle Road, Hove, Brighton, the wife of Roderick Arthur Clapham, M.A., M.D., of a daughter.

## Marriages.

FIELDING—OXENHAM.—On Aug. 5th, at St. Mary's, Lewisham, Saville James, second son of Dr. and Mrs. Fielding, of Norwich, to Grace Horswill, elder daughter of Mr. and Mrs. Edward H. Oxenham, of Catford.

STEPHENSON—LAWRANCE.—On Aug. 3rd, at Great Ayton Parish Church, William Stephenson, M.D., F.R.C.S.E., Professor, University of Aberdeen, to Alice Irene, third daughter of the late James Lawrance, Esq., of Melbourne.

## Deaths.

GUILLEMARDE.—On Aug. 7th, at Eltham, Kent, in his 64th year, Arthur George Guillemard, of Eltham, and 3 Arlington Street, London, third son of the late J. Guillemard, Esq., M.D., of Eltham.

### TO MEDICAL ELECTRICIANS AND MASSEURS.

Unique opportunity of acquiring a FREEHOLD PROPERTY and the GOODWILL at a moderate price.

CHELTEMHAM.—For Sale, by order of Executors in consequence of the death of the Owner, BEECH HOUSE, a centrally situated Freehold Residence, with good accommodation and Garden, situated on tram route, and within three minutes of G.W.R., and close to the Public centres, for many years in the occupation of Mr. G. B. Francis, Medical Electrician, who carried on thereat a highly successful practice. Full particulars from the Sole Agents, G. H. Bayley and Sons, 4 Promenade, Cheltenham.

# IRISH POOR-LAW AND LUNACY INTELLIGENCE,

Being the Supplement to the "Medical Press and Circular."

WEDNESDAY, AUGUST 11TH, 1909.

## Notice to Correspondents.

Poor Law Medical Officers and other subscribers to THE MEDICAL PRESS AND CIRCULAR are invited to make use of the facilities provided by the Management of the Journal for obtaining information on all matters connected with the Poor-Law Medical Service or the Medical Profession generally in Ireland.

The Editor will be glad at all times to receive letters or marked copies of newspapers dealing with matters of medical interest. All communications must be addressed to the Office of the Journal, 18 Nassau-street, Dublin, and should be delivered not later than Saturday morning to ensure attention in the issue of the following week.

## EVENTS OF THE WEEK.

THE Journal of the Irish Medical Association for August is chiefly concerned with letters from four correspondents. Three of them are concerned with the letters of Drs. Powell and Crinion which appear in the number for July, and we are glad to note that they emphatically condemn Dr. Crinion's attempt to introduce sectarian discord into the working of the Association. Regrettable as his action was, that of the Hon. Secretary and Editor in publishing this letter is more so. He knows that sectarian matters are excluded, and that their introduction would be prejudicial to the interests of the Association. Dr. Powell's letter is on an entirely different plane, it would have been better if he had omitted imputing motives. Imputations of that sort so far from strengthening, tend to weaken his case, but it's a perfectly fair question for discussion whether a special Parliamentary Committee is preferable to the Committee of Council, whether such a Committee should be chiefly composed of Poor Law Medical Officers.

The government of the Committee of Council has not been too successful in the past, nor as long as the present system exists, which necessitates its being composed almost exclusively of Dublin men, can it hope to have the unquestioned confidence of the Association. Whether, however, a Parliamentary Committee similarly limited as to constitution, would yield better results and command the confidence of the country members is doubtful.

Undoubtedly reform of the Poor Law and Medical Charities Services is of supreme interest to the medical officers, but it is of no less importance to the profession at large and the general public, and we think that the Committee of Council is quite as capable of enlightened insight into the problems involved as the Committee, whose decrease by lapse of time and not by Dr. L. Kidd's sacrilegious hands, Dr. Powell laments.

Furthermore, as Dr. Olpherts points out the Irish Medical Association is not a Poor Law Medical Association. Under the influence of its officials and *Journal* it has assumed that role and lost ground accordingly with the majority of the profession.

We concur with Dr. Powell, though from an entirely different point of view, that the "Poor Law Medical Officers will have no one to blame but themselves if they go on subverting their interests to the Irish Medical Association." They should look after, and take care of, their own interests themselves, and not ask the Association to do so for them; its function is to bring to the aid of individual medical men, Poor Law and other Officers, the weight of the influence and opinion of the entire profession when needed, in support of their righteous aspirations.

We report in another column the references of the Local Government Board to the claim of Dr. Dillon on the Listowel Guardians for for consultation in a midwifery case. Passi-

over the very doubtful interpretation placed by the Local Government Board on the cases of Flood v. Ballyshannon Guardians, and Olpherts v. Downpatrick Guardians, the position they take up as regards the liability of the Relieving Officer is peculiar in the extreme. "Heads, I win; tails, you lose." The Relieving Officer has not the power, they say, to pledge either his own credit or that of the Guardians. Therefore, any bargain he makes is without force. However, the statutory duty is put on the Relieving Officers to provide a consultant when required. It is for the consultant to make the bargain, and obviously if the Relieving Officer is, by direction of the Local Government Board, to disclaim all responsibility, then it will be necessary to demand payment in advance. Medical men cannot be coerced either by Boards of Guardians or a Government department into working for insufficient fees.

His many friends will have learned with sorrow of the death of Dr. Robert Kenny, one of the Medical Officers of the North Dublin Union. Though by no means an old man, Dr. Kenny had failed much in health since his wife's death a few months' ago, and when he contracted pneumonia a couple of weeks ago, he made but little stand against it. For many years Dr. Kenny, like his brother, the late Coroner of Dublin, took an active interest in politics, though, unlike his brother, he did not enter Parliament. Although a strenuous politician, he had friends in every party, for his kindness and humour won the affection of all who knew him. As Medical Officer of the North Dublin Union he was much beloved by the poor, whom he treated with characteristic humanity. On more than one occasion he successfully defended against the niggardliness of the Guardians his management of the wards in his charge. It will be long before his friends forget "Bob" Kenny's genial face and kindly spirit.

#### BANBRIDGE UNION.

Some weeks ago the Banbridge Board of Guardians adopted a resolution limiting the holidays of the Dispensary Medical Officers to two weeks, and fixing the remuneration of the *locum tenens* at three guineas per week. On receipt of the minutes of the meeting at which the resolution was agreed to, the Local Government Board wrote down asking them to re-consider their decision, and allow the doctors the full term of four weeks' vacation, and to remunerate their substitutes at the rate hitherto paid, viz., four guineas weekly. The discussion which ensued on the reading of this communication, was prolonged, and, at times considerably heated, but eventually the resolution was rescinded, and the suggestion of the Local Government Board acceded to by a majority of 35 to 4. At a subsequent meeting a letter was read from the Local Government Board sanctioning the arrangement. At the same meeting, Dr. James Moag, Medical Officer of the Loughbrickland Dispensary District, wrote, applying to the Guardians to grant him four weeks' leave of absence, and stating that Dr. Chancellor Banbridge, Medical Officer of the Union Workhouse, would as his *locum tenens* at £4 4s. per week. A number of Guardians objected to the medical officer nominating his *locum tenens*, and contended that the Board should have the right to make the appointment, which, it was also contended, should go round all the doctors in the Union in turn, and after a lengthened discussion on the matter, it was eventually decided by 10 votes

to four, that Dr. Boyd, Banbridge, be appointed as *locum tenens* during Dr. Moag's absence at the rate of four guineas per week. We hope and trust, however, that Dr. Boyd will not allow himself to be made a catspaw of by a few ill-grained Guardians for the purpose of sowing discord amongst the medical officers and that by informing the Guardians there are many and cogent reasons why a dispensary doctor should be allowed to select his own *locum tenens* to whom he must, at least, in all rural districts, hand over the care of his private patients, he would let them understand that it is in the interests and for the convenience of all concerned that the doctor's nominee should have the refusal of the position. Such a refusal on his part will, we have no doubt, place him on a higher plane with his professional brethren, and support that doctrine of combination, the exercise of which eventuated in the passing of the resolution which did us much, it not more, for the substitutes as it did for the medical officers themselves. o

#### IRISH MEDICAL MATTERS IN PARLIAMENT.

LUNACY IN IRELAND.—In answer to Mr. Vincent Kennedy, who quoted from the report of the Inspectors of Asylums in Ireland, Mr. Birrell stated that he had seen the statement referred to. He was informed by the inspectors of lunatics that in 1880, when the population was estimated at 5,202,648, the number of lunatics under care in Ireland was 12,982, and that in 1908, when the estimated population was 4,371,436, the number of lunatics under care was 23,931, an increase of 10,949. The increase had been continuous, but had tended somewhat to fall off in recent years. In England the increase in the registered insane between 1880 and 1907 was 52,971. In Scotland the increase between 1880 and 1908 was 8,185. The Government had had before them a report dealing at length with the causes which, in the opinion of the inspectors, had contributed to swell the numbers of insane in institutions in Ireland. This report was presented to Parliament in 1906 (Cd. 3126).

#### THE TUBERCULOSIS PREVENTION ACT.

The recent discussion which took place at the Dublin County Council relative to the proposed adoption of the Tuberculosis Act may be taken as a fair sample of what is to be expected all over the country. The Dublin County Council is certainly as progressive a body as, if not a more progressive body than, most of the other County Councils, and it is a bad portent for the success of the Act when this Council has postponed its adoption for a year. We report the discussion in full as it is of importance, and as it may help those who are trying to bring about the adoption of the Act by showing the points which have to be met:—

A memorandum relating to the objects of the Tuberculosis Prevention Act, 1908, was submitted.

Mr. Shannon, solicitor, explained some of the provisions of the Act, and pointed out that the sanitary authorities throughout the county could adopt the Act with the consent of the County Council. The matter came before the meeting in connection with a communication from the Kingstown sanitary authority, who had decided to adopt the Act subject to the approval of the County Council. It would be for the Council to consider whether they would approve or not.

Mr. Hannon asked if a person were pronounced to have tuberculosis was that person to be banished for life from society and from his friends. He thought that that was the meaning of the Act.

The Chairman said that the patients would be as well and as humanely treated as possible, and the public at large would be saved from the possibility of contagion by contact with those who were affected.

Mr. Hewson said that the chairman was presuming that they had a county sanatorium.

Mr. Hannon stated that everything was presumption.

Mr. Graham asked in the case of the bread-winner of a family who might be pronounced to have the disease, and might in consequence be removed, was there any remuneration or any means of support for his family.

Mr. Hewson thought that before adopting the

provisions of the Act, or giving sanction to their adoption, in any part of the county they should see how the dispensary system was working, and not adopt suddenly an Act which might cast out the bread-winners of the people without any place to keep them except under the Poor Law system.

Mr. Collins said the people wanted education before anything was done. At present it looked as if the Act would be a great hardship on the poor.

Mr. Bunbury said if the people of Kingstown were consulted 90 per cent. of them would oppose the adoption of the Act. At a recent meeting of the Ratepayers' Association a resolution to that effect was adopted, and a deputation was appointed to wait on the County Council.

The Secretary then read a resolution which had been sent by the Kingstown Municipal Reform Association disapproving of the adoption of the Act, and stating that it would be injurious to Kingstown as a health resort, and would also be a hardship on the poor.

Mr. Collins thought that the country had been injured by the agitation that had been carried on.

Mr. Mooney suggested that the matter should be postponed, so that they might have an opportunity of fully considering the matter.

Mr. Hannon said there was no provision to meet the requirements to put the Act in force.

The Chairman said that even when the Act was in operation there was no power to remove a person against his will.

Mr. Hewson said there was every power to order patients to be removed, and to order the disinfection of premises.

Mr. Baggot said that if the clauses were put into force they would practically brand the people as lepers.

It was ultimately agreed to receive the deputation from the Kingstown Municipal Reform Association which consisted of Messrs. O'Curry, Gilmartin, and Weir. The deputation protested against the adoption of the Act on the ground that it would ruin Kingstown as a health resort.

The members of the deputation having retired.

Mr. Mooney stated that he was of opinion that it would be desirable to postpone the matter. It would place Kingstown in an invidious position if the Act were put in force there and not in any other part of the county. If adopted by the County Council, it would be well that the Act should be given to several places at the same time.

Mr. Hewson did not wish to be taken in opposition to the noble woman who had spent the greater part of her life in benefitting the poor of Ireland.

It was finally decided to postpone the consideration of the matter for twelve months.

At a recent meeting of the North Dublin Guardians the following resolution was passed unanimously:—

"That the Council refuse to put in force the Tuberculosis Prevention (Ireland) Act, 1908, until there is in existence a suitable, fully-equipped sanatorium, capable of accommodating all the patients sent in from the North County Dublin; that the Government provide State aid to same, as in other countries where a similar Act is in force, for families who may be deprived of their bread-winner, and not force whole families into pauperism and to become a burden on the ratepayers; that the Government be asked to pass a Bill dealing with this matter."

#### FEE FOR CONSULTATION.

At the last meeting of the Listowel Guardians, a letter was read by the assistant clerk (Mr. D. O'Connell), from the Local Government Board, stating they had under consideration the claim of Dr. J. T. Dillon for a fee of £5 for professional assistance rendered by him in a midwifery case of the acting medical officer of the Tarbert Dispensary District, and in reference thereto the Local Government Board had to point out that it was decided by the High Court of Justice in the case of Flood v. Ballyshannon Guardians, and also in the case of Olpherts v. Downpatrick Guardians, that the Boards of Guardians were not legally liable for any greater remuneration of a medical practitioner employed

under Article 21 or Article 22 of the Dispensary Regulations than that prescribed by Article 23. As appears from the latter cases, it had not yet been decided whether Guardians were liable for medical attendance on the destitute poor persons relieved under Section 7 of 10 Vic., cap. 31. The Board did not consider that the relieving officer could be personally liable for the consultant's fee where he was acting in his official capacity to the knowledge of the medical practitioner employed.

#### TYPHOID AND CREAMERY MILK.

At a recent meeting of the Thurles Guardians, the Local Government Board, in forwarding Dr. Browne's report regarding the outbreak of enteric fever at Currahaha and vicinity, in the Borrisoleigh Dispensary District, pointed out that the occurrence emphasised the necessity for close supervision over the sources of the public milk supply by careful administration of the Dairies, Cowsheds, and Milkshops Order, 1908, and suggested to the Council the desirability of their making a joint appointment of a veterinary surgeon in conjunction with the Thurles Urban Council for the purposes of the Order, in which event the expense on each Council would not be serious.

Dr. Browne, in his report, after going into the details of each case, stated:—In all, up to the present, there have been twenty-three seizures. The only circumstance in common to all is the milk supply from the creamery at Currahaha. None of the families attacked used the same water supply. No suspicion is attached to the water used for dietetic purposes by any of the families, but the water used for washing the milking utensils in some instances was subject to contamination. The water supply used at the creamery is taken from a stream, and is liable to pollution. The milk from the affected farms was being sent to the creamery up to the time the medical officer first saw the patients. The manager of the creamery informed me that the milk was always sterilised before being returned to the customers, and was heated to a temperature of 195 degrees, and kept at this temperature for some minutes. However, I consider that all the circumstances point to the creamery separated milk as the source of the infection.

Dr. Browne said since he had written the foregoing report he was sorry to say there had been a good many more cases—28 in all, and there were twelve or thirteen in the Nenagh Union, which would bring the total up to 40. If they had a proper supervision over the milk supplies, as the Dairies Order enabled them to have, this outbreak might have been avoided. He was afraid the farmers did not always wash their milking utensils with clean water. In several instances he found they were washed in sinks where ducks and geese had recourse.

We understand that the epidemic is still spreading, fresh cases having occurred.

#### CARRICK-ON-SUIR UNION.

At the weekly meeting of the Carrick-on-Suir Board of Guardians, an application was read from the five medical officers of the Union for increased salaries. This was the tenth time within the past two years the doctors have applied for increased salaries. On each occasion the application has been marked "read."

Mr. Thomas F. Morrissey, who all along has been active in opposing the doctors' application, now moved that the application be marked "read," as there was at present a resolution on the books deferring the consideration of the doctors' application for increased salaries until some action is taken by Parliament as regards the Poor Law Commission's report.

The application was marked "read" without further discussion.

#### LONGEVITY IN SHILLELAGH.

Dr. Brady of Carnew has written to the Shillelagh Guardians thanking them for granting him an increase of salary. He desired, however, to point out that according to the graded scale adopted by the District Council, an officer would require to serve for eighty years before obtaining the maximum salary of £35

fixed for the position of medical officer of health, and he would ask the Council to be good enough to reconsider the scale of increments in that case.

No order was made.

Even in Shillelagh eighty years' service is too much to expect.

#### ADMISSION TO WORKHOUSE HOSPITAL.

The Local Government Board has written to the Clogheen Guardians in reference to the case of Mrs. Neathery stating that it appeared that the woman went to consult Dr. Walsh, and he, owing to the urgency of the case, recommended her admission to hospital; her husband, a small farmer, guaranteeing cost of treatment and maintenance. The Master refused her admission, and she became seriously ill. She was admitted next morning on an order from the Relieving Officer, but subsequently died, her death, it was alleged, being accelerated by the delay in her admission. The Master maintained that he had acted properly. The Local Government Board requested that the attention of this officer be called to Article 64 (1) of the Workhouse rules, from which it would seem to be his duty "to admit paupers into the Workhouse in obedience to any order made under Article 1, and

also persons applying for admission who may appear to him to require relief through any sudden or urgent necessity." All such admissions should be reported to the Guardians, who would decide whether the person was to continue in the house or not. The duty cast on the Master was analogous to that imposed on the Relieving Officer, who was responsible for offering immediate relief in all cases of sudden and urgent necessity until next meeting of the Guardians, though it may subsequently be found that the parties may not be properly relievable by the Guardians. It was clear, therefore, when a poor person, dangerously ill, seeks admission, the Master should admit him.

On the motion of Mr. Heffernan, seconded by Mr. Galvin, an order was made pointing out to the Local Government Board that Mrs. Neathery could, in no sense, be considered a poor person. Her husband had a comfortable house and 57 acres of land valued at £43 10s. Consequent on the letter of the Local Government Board of March 2nd, which stated—"That they (paying patients) can be admitted only by the Board of Guardians," an order was made on the Master and other officers, referring them to this letter. The officials on this occasion only carried out the directions of the Guardians in accordance with the Local Government Board's rules.

#### THE DUBLIN INSTITUTE OF BACTERIOLOGICAL AND CLINICAL RESEARCH, LABORATORIES—21 LOWER ORMOND QUAY, DUBLIN.

Are now Open to receive all species of material for Clinical and Bacteriological investigation.

All investigations carried out under the personal supervision of the Director. Prospectus and Scale of Charges on application to the Secretary.

Telephone—No. 1851, Dublin.

Telegraph—Bacillus, Dublin.

Director—Mr. C. JOCELYN O'HEHIR,  
Late Bacteriologist to the City Laboratories, Dublin.

No. 7.

## NOTES AND COMMENTS.

**The Annual Representative Meeting of the B.M.A.** The Annual Representative Meeting of the British Medical Association, judging from the published report, proved a great success. A number of important matters were discussed and a free interchange of opinions

took place, with the result, in some cases, of resolutions that cannot fail to be of future value as a more or less authoritative pronouncement of medical views. The finances of the Association came under review. One speaker pointed out that in 1900, with an income of £43,263, there was a surplus of £6,272, whereas in 1909, after omitting the capitation grants to the Branches, the income was £49,736, or more than £6,000 a year increase, and there was a surplus of only £732. That members get good value for their money must be generally admitted, but a solid reserve fund should not be altogether impossible, with a progressive income. The members cost nearly £50,000 per annum.

Mr. Mooney stated that he was of the opinion that it would be desirable to postpone the matter. It would place Kingstown in an invidious position if the Act were put in force there and not in any other part of the school. If adopted by the County Council, attention. Among other points, it was agreed that the special officer should be School Medical Officer, and not Assistant Medical Officer of Health, and the payment by fixed salary approved, with capitation grants in sparsely populated districts. Further, payment per child was generally disapproved; when necessary a minimum sum of not less than 2s. 6d. was suggested.

**Treatment of defective school children brought forth a crop of resolutions of vital importance to general practitioners.**

The reference of such patients to public medical charities was disapproved, and it was resolved that they ought to be sent to registered medical practitioners. The underlying feeling, and a quite legitimate and proper one, was that defective school children should be treated by medical men, who should be paid at a fair rate for their services. In this way the meeting definitely and specifically opposed the reference of such patients to the Poor-law. A resolution was passed suggesting that in case of guardians or parents unable to pay proper fees for defective children, a voucher should be issued by the local authority empowering treatment at fixed fees by any available medical practitioner. By an overwhelming majority (108 votes to 8) the principle of school clinics was approved in towns, as convenient places where treatment could be carried out by private practitioners. So far as the metropolis is concerned,

the action of the Education Committee in making arrangements with certain London hospitals was disapproved. Some of the other points that occupied the attention of the meeting will be touched upon in this column at a later date.

### **A Water-Cure.**

WELSH "revivals" have been somewhat in the background of late years, but lest anyone should consider that the quality of faith is lacking in that section of the Celtic fringe, a real miracle has been supplied of late to show that credulity is not dead. A certain Elizabeth Bleasdale, having three years ago damaged her thigh by a fall, was informed by the doctor that she had a "tuberculosis hip," and though everything possible had been done for her, she failed to get relief. A week ago she went to Holywell and bathed in St. Winifride's well, having to be carried into the water for the purpose. "Immediately on leaving," she said, "she felt the hip flowing easy," and in a few days was able to discard her crutches and an iron splint she wore. Dr. B. the next day she walked five miles, and now all she feels is slight stiffness of the joint, which causes a "hardly perceptible limp." The priest in charge of the well told her it was no use her bathing unless she had faith in its properties, and she declared she had faith that she would be cured. Now she proposes to go every year to bathe, as she is sure that in this way the cure will be permanent. With all sympathy with journals that have to tide over a silly season, we think we might be spared such stuff as this.

### **Hard-Earned Increment.**

THE "unearned increment" is much to the fore just now, and on the political side of the question we have, of course, nothing to say, but that ingenious disputant, Mr. Harold Cox, who occupies the uncomfortable position of a Free Trader who is opposed to land taxation, has been trying to defend the increment value which accrues to a ground-landlord by the increasing density of population on his ground, by arguing that he (the landlord) is as much entitled to the untaxed benefit of this increase as a medical man whose practice is increased by growth of population in his neighbourhood. Without arguing about the rights and wrongs of the landlord, we must say we stand aghast at the analogy. A medical man with free choice of a neighbourhood to practise in naturally chooses a growing one, and if his judgment is justified by the event and his *clientèle* increases, he naturally makes a larger income. But every penny of that income is earned by the sweat of his brow, and not a farthing comes in that

is not earned. The landlord, on the other hand, may be living in Timbuctoo, and even have forgotten he owned the land in question, but the increased value goes on. One of the hardships of a doctor's lot is that all his increment is earned, and hardly earned, and the moment he is laid aside by illness or age his income stops absolutely.

#### Notification of Births.

THE persecution of medical men in connection with the notification of births seems about to begin in Paddington. Last week twelve parents were summoned before the magistrate, Mr. Denman, for not notifying the births of their children to the medical officer of health within thirty-six hours. The defendants, with one accord, said they had no idea there was such a law, and they were consequently let off with a fine of 3s. each. Now, if this shows anything, it shows great slackness on the part of the Borough Council in not letting parents know that this law has been adopted in their district, as it is ridiculous to suppose that twelve persons indiscriminately drawn from the district should not have known the fact if it had been properly brought to their notice. What, however, concerns us more is that the prosecuting solicitor said that, as the doctors were equally liable with the parents, it might induce them to notify if they were summoned and kept waiting about the court all the afternoon. The report adds: "Mr. Denman was understood to say that possibly that would be the best thing to do." We hope that Mr. Denman was misunderstood, for we cannot conceive a responsible magistrate backing up an attorney in a spiteful attempt to inconvenience doctors and to disorganise their practices because the Borough Council had failed in its duty of informing parents that a new law has been adopted.

#### Sanitation in West Africa.

THE Colonial Office has just issued a report by Professor W. J. Simpson, formerly of Calcutta, on the outbreak of plague which occurred in Accra and the surrounding villages in January, 1908. After bringing the outbreak under control, Professor Simpson made a tour of inspection throughout the Colony, visiting the principal towns and a large number of villages. The outbreak of plague lasted from January until July, and there were 344 cases, of which 300 terminated fatally. The points most worthy of notice were the readiness of the natives to accept preventive inoculation, and the success that attended its employment. It was performed upon 35,000 persons without a single recorded accident or ill effect, and only four of the inoculated persons subsequently suffered from plague, and of these one recovered. Professor Simpson's report on the general sanitary condition of the Colony is to the last degree unsatisfactory. The health of the Colony could be dealt with only by a fully-organised department, and this not existing, the damage to the health of Europeans must continue excessive. Not only are sanitary measures of the most primitive type virtually unknown in towns and villages, but no systematic and continuous preventive measures are undertaken to protect inhabitants from the conditions that generate malarial fever and agents which convey disease. The remedy lies in the organisation of a special health department responsible for correction of existing evils. This reform is considered in a second report of a Departmental Committee appointed to inquire into it, and the matter is now engaging the attention of the Colonial Office, and of the Earl of Crewe, the Secretary of State.

## LEADING ARTICLES.

### THE LONDON COUNTY COUNCIL AND THE HOSPITAL TREATMENT OF DEFECTIVE SCHOOL CHILDREN.

THE question of the treatment of defective school children is one of grave importance to private medical practitioners throughout the Kingdom. The Act that made the inspection of school children imperative was so obviously sound that it secured a practically unanimous verdict of approval. The application of the measure, however, has raised a host of difficulties, and the permanent solution of the problem upon a satisfactory basis appears to be a somewhat remote matter. In London the Education Committee of the County Council, after much consideration, adopted a method which merits the serious attention of every medical practitioner in the United Kingdom, inasmuch as the machinery of the metropolis is likely to become the pattern and example of all other urban education bodies. In fact, the London Committee has made arrangements with certain medical charities for the treatment of a certain number of defective school children, and this action raises questions that should be threshed out and faced to their final issue by the medical profession. A lead has been given by the Annual Representative Meeting of the British Medical Association, which has recorded its formal disapproval of the action of the Education Committee of the London County Council in entering into the arrangement mentioned. The motion was brought forward by Mr. H. Beckett Overy, seconded by Mr. Donald Armour. As the proposer said, only a small proportion of the children would be provided for under this plan, which failed in any attempt to grapple with the subject in its entirety. Sir Victor Horsley spoke of the action of the County Council as ridiculous, because it attempted to provide for a few hundred of the 70,000 or 80,000 school children in want of treatment. There is much to be read between the lines of the report of the discussion in order to realise anything like its full import. One of its most significant points appears to lie in the expression of the hope that the medical staffs of the hospitals will do all in their power to prevent the "abuse of voluntary charities and inadequate provision for a public evil." It remains to be seen whether the members of the honorary staffs of the London voluntary hospitals will act on this plainly-worded note of supplication and warning. Here is a large amount of public work—to use a homely phrase—going begging. Is it to go, as it should legitimately go, as a paid service to the medical profession, or is it to be added to the already disproportionately great sum-total of gratuitous toil borne by medical men? The answer to this question to a great extent depends upon the attitude of the honorary staffs of the voluntary medical charities of London. If they use their influence to dissuade their boards of management from listening to the wiles of the tempter, and, if necessary, take the further step of refusing to treat school children, then the County Council will soon find the doors of every hospital in the metropolis closed to the treatment of school children. It is, of course, a great temptation to hospital boards of management to add to their revenues by taking fees from the Council, and

receiving patients for treatment which *per se* will not cost them an additional farthing. At first blush, the temptation to the medical men on their honorary staffs is almost equally great. Here is the chance of helping the institution to which they are attached by seeing a few more gratuitous patients. A little further consideration, however, will show that to play into the hands of education and hospital boards is to inflict a grave injury upon a great class of private practitioners outside the hospital. It is clearly to the interest of the consultant class that their bonds of union and friendship with their extra-mural brethren should be close and harmonious. In the dispute the disunion of the medical profession is thrown into high relief. Through the want of strong and concerted action they lie at the mercy of public bodies and of hospital boards, while the kindness and humanity of one class of medical men is played upon at the expense of another. In any case, it is to be hoped that those hospitals that have gone over to the enemy will be put upon their defence. The members of the medical staffs of those institutions will receive a communication from the British Medical Association setting forth the views of that body as to the attendance of school children by medical charities. There are not only a few of the hospitals that have entered into arrangements with the Council, and the views of individual members of the staff and of the protests they have made, or the reasons by which they have been swayed, will doubtless in due course of time be obtained by the Association. Meanwhile, medical men generally will do well to keep themselves advised as to the views of the politico-medical committee of the British Medical Association.

#### THE ENDOWMENT OF CANCER RESEARCH.

ONE of the most munificent acts of generosity which it has been our pleasure to chronicle is that of the late Mr. Harry Barnato, who has bequeathed the sum of a quarter of a million sterling for the endowment of cancer research. The sum was left to perpetuate the memory of his brother and nephew, by the establishment of a charitable institution, and the testator's executors, realising the great problems at issue, have decided that this object could be most worthily accomplished by devoting the bequest to the building of a "Barnato Institute" for the reception of cancer patients, which shall also include the erection and elaborate equipment of cancer research laboratories. Thus, as it were, under one roof, the opportunity for investigating the intricate problems of cancer, both from the scientific as well as the clinical aspect, will be rendered possible. From the professional standpoint, indeed, nothing could be more excellent than this arrangement. The obviously weak point in the scheme of the Cancer Research Fund is the want of provision for dealing with the disease from its clinical side, that is to say, all those facts having an important clinical bearing which the Cancer Research Fund may happen to evolve in the future will always have to be submitted to the tribunal of the bedside before their value to human beings could be determined. To man it can matter not a jot how cancer runs its course in mice, unless he

can gather from these small rodents facts which will enable him to deal more successfully with the disease in himself. There has rather been a tendency of late to assign too much importance to the scientific aspect, as if that were the only problem involved in the case. Possibly this may be due to the fact that more public attention is directed to the matter than was the case in former years, through the medium of the published reports of the Cancer Research Fund. However that may be, it is impossible to deny that, after all, the chief aim and purpose of all cancer inquiry is to determine how that fateful scourge to humanity can be best brought within the control of modern treatment. Possibly, it may be that in the discovery of a cure for the disease, some method may be casually alighted upon with which scientific investigation has had nothing to do. There are instances of such in the past history of our art. For example, Jenner's great discovery of vaccination for small-pox was as much divorced from scientific research as a therapeutic advance of such magnitude could possibly have been. There were no research laboratories in his day, no microscopes, no bacteriology, nothing which could render him, scientifically, the least assistance in the problem which he ultimately solved. Thus, here was, at least, one instance in which science had no hand in the evolution of one of the greatest benefits conferred upon humanity. Nevertheless, on looking back on the ages past since Jenner's immortal discovery, it is obvious that unless something had been done to control the ravages of small-pox, the world might have become largely peopled with deformed, blind, and otherwise mutilated persons, as a consequence of which all human progress would have been arrested. Thus there is no beaten track by which Nature reveals her secrets; the path of science may appear to us the safest, and the most likely one to follow, although the most thorny, in the pursuit of knowledge, and we may learn much as we make progress by the way. But there is no certainty that the goal will be reached by this means. It may happen, therefore, with cancer, as it did with small-pox, that some by-path, with empiricism as its basis, may be discovered which will lead to the attainment of that object at which all cancer research work is aimed. Clearly, on these grounds, it is impossible to lose sight of the importance of studying the clinical aspect of this great question. We presume that in the Barnato Institute every facility will be provided, under the control of the staff of Middlesex Hospital, to submit to the test the reputed remedies in the treatment of cancer, which may be regarded as worthy of a trial. A system of control of this kind would undeniably be of much service, both to the profession and the public. There would then be no excuse for the "yellow press" claiming, in the largest newspaper type, that the "conquest of cancer" had been reached, or for publishing irresponsible statements upon the subject, by flamboyant contributors, before the Barnato Institute had been appealed to with a view to determining the validity or otherwise of the claim. We believe, therefore, that a great future lies before the Institute, as fulfilling a want in the great cancer problem which has hitherto, in the public interest, been severely felt. To have an Official Court of Appeal is a matter of such supreme importance to humanity as that of the clinical value of reputed remedies for cancer must obviously prove advantageous to mankind generally.

## CURRENT TOPICS.

### "Secret" Remedies.

THE British Medical Association has for some years been carrying on a systematic examination of so-called secret remedies. The constituents of these, being, as a rule, merely small quantities of common drugs, are easily recognisable by the usual processes of chemical analysis. The series of reports published periodically in the *Journal* has now been reproduced in pamphlet form. It constitutes, in fact, an indictment of the traffic in quack medicines which, if properly forced upon the attention of the legislature, ought to go a long way towards promoting amendment of the law sufficient to put an end to the worst forms of a pernicious system under which the poor and ignorant classes are the worst sufferers. The indictment is not less forcible because it consists almost entirely of boldly-stated facts, without any comment or attempt to emphasise them. The pretensions of the advertisements are first quoted, next the constituents of the remedy are described, and then its intrinsic value is given. The outlay of the quack nostrum-monger is nearly all in advertisements; the cost of his medicaments is never more than a small fraction of the selling price. Heal-all pills and potions rarely contain anything more costly than a small dose of aloes, whilst one large series of remedies for a multitude of different maladies are simple pillules of sugar. Cancer cures vary between coloured water and coloured grease, and the vendors do not hesitate to condemn the cruel surgeon and his knife, whilst urging sufferers to trust implicitly in their infallible cures. The profits in cosmetic quackery are enormous, fat cures, for instance, being rarely composed of any ingredients more costly than acidulated coloured water. With this pamphlet before them—and we hope it will be put before them in a way to compel attention—it will be interesting to see whether newspapers that set themselves up as censors of morals, and guardians of the public welfare, will continue to open their columns to lying advertisements, and put their endorsement on them by printing them in the form of editorial articles.

### The Heat and Poor Children.

MAGNIFICENT weather such as now prevails does not prove an unmixed blessing to the hundreds of thousands of children inhabiting the poorer quarters of London and our great cities. Not only are certain deadly infantile diseases always associated with prolonged summer heat, but the schools are closed, and the only holiday recreation grounds for multitudes of the older children are the slums, the courts and alleys in which their homes are placed. Some small percentage of the children obtain brief outings in the country, but the majority are condemned to stay at home. It is not surprising to find this question a subject of discussion in the papers, and that a plea is being made for a more systematic attempt to organise and direct the recreation of children on the lines already successfully tried at home, and worked on a much more extensive scale in the chief cities of the United States. The cost is very slight. The school buildings and their playgrounds, with other available open spaces, give enough room; it is only necessary to draw the children into them, and then teach them to play. The Shoreditch Borough Council has shown the way in this movement. They have placed their ground in Goldsmith Square under the superintendence of the Play Centres Committee and their trained kindergarten teachers. Poor children, unaided, cannot play because they do not know how to. Under proper superin-

tendence they soon learn, and the experience everywhere demonstrates the enormous improvement, physical and moral, which is brought about in the little ones who are taken away from the dirt and dangers of the streets, and unconsciously imbued with the spirit of order and discipline which wisely-directed play undoubtedly provides.

### Deaths under Anæsthetics.

DR. WALDO, who has for some time devoted much attention to the subject of deaths under anæsthetics, made a very remarkable statement at an inquest in Guy's Hospital on the 30th ult. He said that out of forty-one cases of deaths under anæsthetics in Guy's Hospital into which he had inquired, thirty-three were due to chloroform or mixtures containing chloroform. The remaining deaths were due to ethyl chloride. We do not know in what proportion of cases ether is used in Guy's Hospital, but we suppose it is sometimes employed, and it is therefore interesting to note that no death from its use has occurred in Guy's in Dr. Waldo's experience. Comparison of English statistics with Irish bear out in similar manner the belief in the comparative safety of ether. In Ireland ether is the routine anæsthetic, and very few deaths under anæsthetics occur. In some English hospitals chloroform is in common use, and deaths are far from infrequent. The question is becoming a very serious one as to whether in these climates—in certain climates there is no choice—an anæsthetist is justified in submitting a patient to the risk of anæsthesia by chloroform, except for very grave reasons. Many anæsthetists find they can manage nearly every case without resorting to chloroform; it is the duty of others to acquire a like skill.

### Bacteriology under the Hammer.

UNDER the recent Tuberculosis Act, County Councils in Ireland have obtained the power of appointing bacteriologists to aid medical practitioners in the diagnosis of tuberculosis. It is probable that, in the course of time, many of the public health authorities will make such appointments, and it is therefore advisable that the terms on which they are made should be well weighed by the medical profession. Two kinds of arrangement appear to be possible—appointment at a fixed salary, or appointment at remuneration according to the work done. It is open to the health authorities to proceed on either of these lines, and in the first instance, at any rate, it is probable the latter plan will be chosen, for, until experience shows the amount of work demanded, it would be difficult to decide on a suitable salary. Whatever plan, however, is adopted, we trust that few authorities will follow the example of the Dublin County Council. This body has adopted the course of putting the appointment up to auction. It has decided, in fact, to write to a number of "eminent bacteriologists," asking them to state the fees at which they would be willing to act. Though not explicitly stated, the suggestion is that the cheapest "eminent bacteriologist" should be employed. We trust that medical men employed in bacteriological and clinical research work will discourage this manner of filling appointments. We can think of no more undignified act than to tender for work in the way the Dublin County Council expect.

### Science in Public Schools.

As so often happens in similar instances, we are indebted to the *Times* for publication of an able summary of the report recently issued by the Board of Education on science teaching in public schools.

The Report is almost completely the work of Mr. O. H. Latter, Science Master at the Charterhouse, and is based upon the replies furnished by forty-six schools out of the seventy-one to which inquiries by circular were made. Most of the best-known schools supplied the information asked for; it is feared that the minority which remained silent had mostly cause for shame in their position in this matter. The movement towards inclusion of science in educational courses was started in 1854. Before that date the subject was virtually ignored everywhere. The movement received its greatest impulse through the action of the managers of the Royal Institution. They arranged a course of seven lectures on the subject. These were given by trusty leading men of the time, Faraday, Whewell, Tyndall, Latham, Daubeny, Hodgson, and Sir James Paget. The lecture by Faraday, at which the Prince Consort presided, created an enormous impression upon public opinion. In the boldest language he made it abundantly clear that the prevailing defects in the exercise of the mental powers among the so-called educated classes were mainly due to the absence of systematic training of the judgment, such as the study of science can alone adequately provide. Since the date of Faraday's lecture great progress has been made, and a fair proportion of cultivated men outside scientific professions—lawyers, politicians, and even theologians—have received of the heaven of science enough to modify sufficiently their intellectual activities. Unfortunately, and as usual, our inferiority to the Germans in this department of education is dwelt upon, and we are reminded that it is largely by the general national recognition of the value of science, and the importance of being guided by it, that she has attained her present position among nations.

#### Nurses and Drug-Taking.

At Birmingham Assizes, recently, a case raising an important question was tried before Mr. Justice Grantham. The action was brought by a nurse against the authorities of Queen's Hospital, Birmingham, for damages for wrongful dismissal. The circumstances which led to the dismissal seem to have been that the nurse, being unwell, took a dose of veronal—ten grains was the amount stated—which had previously been prescribed for her by a medical man, but which was not specifically ordered on this occasion by any of the medical staff. She overslept herself in consequence, and had no time for a proper meal before going on duty, but she thought herself fit for her work. The night sister on her rounds found her unwell, and there seems to have been something of "incident" between them; at any rate, it does not seem to have been disputed that the nurse was drowsy and heavy, and that there was a dying patient in the ward. The long and short of it was that she was sent to her room, where she was kept for two days, when, after a further interview with the matron, the secretary and the chairman of the committee, she was dismissed. There does not appear to have been any more in the case, and the question raised was whether it was a breach of discipline, as understood in hospital life, for a nurse to take a dose of an hypnotic without specific medical orders from one of the staff. From the hospital point of view it is important that this matter should be made plain, as a nurse possesses abundant opportunities for obtaining dangerous drugs, and there may be serious consequences to patients if she is not fit for her duties. On the other hand, under British law a person is allowed to dose himself as much as he likes with what

drugs he likes, and over-dosage with alcohol is the only one which constitutes a misdemeanour. The jury evidently found themselves on the horns of this dilemma, for they failed to agree after an hour's deliberation, and were ultimately discharged.

#### Professor Cleland's Farewell.

It was peculiarly fit that his University should entrust to Dr. Cleland the duty of giving the Address to the Graduates in Medicine and Surgery at the recent graduation ceremony in Glasgow. The words of one who, having performed his life-work, is going to well-earned rest, to those who are eagerly entering on the struggle of life, seldom fail to be impressive. When the words fall from the lips of one who, like Dr. Cleland, has served his day and generation strenuously, thoroughly, wisely, and the hearers are bound to him by the ties of affection and reverence that generous young men feel for a wise teacher, only the foolish are uninstructed. In terse, simple words, with no attempt at rhetoric—but on that account all the more eloquent—the teacher spoke of factors at work in life. Error has always its course in mundane affairs. Defect of knowledge produces error as to fact and action, but still more does weakness produce error which may lead to terrible results. In medical men, even more than in others, is weakness to be conquered, for it is dangerous to others as well as to oneself. One must get over the desire to please, and be firm, perhaps, in decisions which cannot but be displeasing. In considering the universe, we see not only wind and water, but organic life, the old "vital force," so much derided, but now coming to its own again. This formative principle, this *vis medicatrix naturæ*, is not merely a biological principle, but a moral one. "There is a *vis medicatrix* which will yet bring the long and laborious evolution of man's course on this planet to a glorious climax." Professor Cleland's farewell words are worthy of him.

#### PERSONAL.

CAPT. J. CRAWFORD KENNEDY, M.D., R.A.M.C., the newly appointed Assistant Professor of Pathology in the Royal Army Medical College, Millbank, is a well-known authority on "Malta Fever," on which subject he was awarded the Gold Medal for his thesis.

PROFESSOR OSLER will deliver the Inaugural Address of the Winter Session of the London School of Tropical Medicine on October 26th. The United States Ambassador will preside.

MR. W. M. MOLLISON, M.C., F.R.C.S., has been appointed Arthur Durham Travelling Student at Guy's Hospital. Mr. Mollison is Assistant Surgeon at the Evelina Hospital, and Demonstrator of Anatomy at Guy's Hospital.

THE Home Secretary has appointed Dr. Robert Trimble, of Preston, to be one of the medical referees under the Workmen's Compensation Act, 1906, to be attached more particularly to Preston, Garstang, and Chorley County Courts, in place of Dr. Edwin Moore, deceased.

A PARTY of French medical men, including twenty-two members of the French Medical Society, visited Dublin during the past week. They were entertained to dinner at the Royal College of Surgeons, and at the Viceregal Lodge by Her Excellency Lady Aberdeen. While in Dublin they visited many places of interest.

# A CLINICAL LECTURE ON ACUTE LEUKÆMIA.

By PROF. ALBERT HERTZ, M.D.,

University of Vienna.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

IN this lecture Prof. Hertz said he was indebted to his chief, Prof. Kovács, for the following observations in acute diseases of the hæmato-poietic organs, and would illustrate his remarks by commencing with the following picture:—

A patient was admitted in a stupid, semi-conscious condition, and from whom little or no information could be obtained. After 14 days' residence he seemed perfectly well, but complained of a slight pain in the left little toe which soon extended up the leg, and in a few days after was quite helpless again. With the onset of the pain it may be mentioned that rigors were observed similar to those which he described he had before admission. Going back to that examination, we find recorded high fever, insensibility, great prostration, and cyanosis in face and extremities. On the left foot was a diffuse reddish-blue colouring extending up the leg, with dark congestion of the other toes. The axillary, inguinal and femoral lymphatics on both sides were greatly enlarged. There was no ulceration of the gums nor any changes observable in the throat. The respirations were deep and hurried, while the lungs had diffuse bronchitic *râles*, but were otherwise healthy. Apex beat of the heart could not be located, though the dulness of area was not increased, but a short systolic murmur with a dull sound could be detected, and no pulse could be found in the peripheral arteries. Meteoric gurgling was present in the abdomen, with a large inguinal hernia which had been replaced the night before admission, but was now impracticable. Liver and spleen were not examined. In the urine was serum albumin with a sediment of hyaline cylinders, leucocytes, renal epithelium and erythrocytes. In the blood hæmoglobin, according to Sakli, was 100 per cent., erythrocytes 5 millions 900, and the leucocytes were 16,800. The erythrocytes seemed to be normal, but the leucocytes had polymorphic nuclei giving neutrophiles 6.7 per cent., with a transition form of 3.9 per cent.; the neutrophile myelocytes were 8.07 per cent., while the large mononuclear ungranulated cells were 80 per cent., and small lymphocytes were only 1.4 per cent. There were no eosinophile cells nor mastoid present.

On looking over the preparations that had been preserved, you will find the cells which have been described as large mononuclear and ungranulated, have a round giant appearance, but bulging at different parts forming lobes which contain chromatin and basophilic protoplasm, and is ungranulated in most of the cells, although a fine neutrophile granular substance may be found in some of them. In many of them the protoplasm had large vacuoles with two nucleoli. It may be noted that many of these cells had transition forms like neutrophile myelocytes.

Shortly after this attack in the Institution, the patient died, and the diagnosis given as sepsis from acute leukæmia.

The post-mortem was conducted by Dr. Wiesner, who found general acute hyperplasia of the lymphatics, enlarged spleen, parenchymatous degeneration of the heart and liver, fatty degeneration of the heart and kidneys, purulent fibrinated pericarditis, purulent metastatic nephritis, with initial fibrinated peritonitis, probably pyæmic. Acute pulmonary oedema was present, with deforming endoarteritis of the aorta, right-sided inguinal hernia, oedema of the left leg and excoriation of the left little toe.

The anatomical changes most prominent were the lymphatic glands, which were large, soft and granular,

of a greyish to dark red colour; spleen and liver greatly enlarged, and the kidneys had a number of small abscesses. The marrow of the long bones of the leg had a yellow colour, but near the upper ends it became reddish.

The bacteriological examination of the fibrin of the pericardium showed purulent cells agreeing with those in the small abscesses of the kidney, and staphylococci with Gram's preparation with agar, a pure culture of staphylococcus pyogenes aureus.

The histological examination was still more interesting. A section of the femor medulla showed considerable change, although the erythrocytes were normal, there were very few leucocytes, particularly of the granular character. The mononuclear were more numerous, large, with a basophile, non-granular protoplasm, but here and there a few eosinophile myelocytes and few erythroblasts were present, but neutrophile myoblasts were entirely absent. When examined macroscopically, the reddish part of the medulla had a granular appearance. All the cellular product appeared to be similar to that found in the blood, particularly the large mononuclear cells with homogeneous protoplasm, as well as the small lymphocytes.

From a section of the ribs these large mononuclear and non-granular cells with stellate vacuoles were present in the protoplasm.

In the spleen the follicles were not enlarged, but the vessels were dilated, and in parts filled with erythrocytes mixed with mononuclear leucocytes.

In the "pulpa" a large number of mononuclear cells with a pale non-chromatic nucleolus were embedded in a basophile protoplasm; the small granular cells had a somewhat bulging irregular nucleus. There were very few polinuclear leucocytes, eosinophile myelocytes or erythroblasts.

The lymphatics agreed in every detail with the spleen, the lymph sinuses containing a large number of cellular matter in the same condition as the spleen.

The lymphadenoid tissue was greatly changed by the increase.

The liver and kidneys had no particular changes beyond the dilatation of the capillaries and the presence of the cell formation described in the other organs. These results point to an acute blood change, probably from the wounding of the little toe, which rapidly infected the blood with the staphylococci, producing change in the spleen, lymphatics, etc.; but that of the medulla of the bone is a separate change of a hyperplastic nature. The peculiarity lies in the poverty of the leucocyte formation, while the erythrocytic apparatus is normal. Of these leucocytes it must be observed the absence of the granular cells was the most prominent.

The small number of white cells in the blood, as myeloblasts and lymphocytes, was strikingly few in number, and might, therefore, be termed large-celled leukæmia, but the peculiarity is that the medullary portion of the bone is healthy, and none of these myeloblasts present, which point to their origin being of an extra medullary hyperplasia, probably arising in the lymphatics or spleen. When these organs are carefully examined we find the pulpa greatly increased, particularly the inter-follicular tissue, while the follicle itself is unaffected, although in some cases it may be found atrophic with all the appearances histologically of myeloid leukæmia. According to Schultz, Myer, etc., this pathological change was idiopathic

in chronic, as well as in acute leukæmia. In the pulpa of the spleen, as well as the lymphatic glands, these myeloblasts were present.

In looking over the literature on the subject, Butterfield records an acute case of myeloid leukæmia, in which he tells us the medulla of the bone was reactionless. He comes to the conclusion that the myeloid centre is an extra medullary organ, probably "metastatic" or due to "colonisation," which would be opposed to Ehrlich and Neumann's autochthonous origin in medulla. The case recorded along with Butterfield's, showing a myeloid increase in the lymphatics with the blood cells found there does not agree with the orthodox opinion that the disease is due particularly in these cases to any osteo-sclerosis or other bone disease. Lehdorff and Zak record another myeloid leukæmia in the aged, where they met with very few granular cells in the long bones, while the fibrous tissue was altered, but the spleen had every appearance of myeloid changes, as myeloblasts and giant cells were to be found in great abundance. They came to the conclusion that these were due to some changes unknown in the hæmato-poietic-lymphatic apparatus, and termed it lymphadenoid leukæmia.

In closely examining my own case for any aplasia in the osteo-medulla which may have arisen from staphylococci pyæmia as the centre of these myeloid cells, while they were found in great abundance in the lymphatics and spleen, I was led to a more critical examination of others of a similar character, of which the following is an example:—A domestic servant, æt. 44, came to hospital on December 13th, 1906, in a somnolent condition, with very little information of her previous history, beyond having had great pain in the head, lassitude, and fever for a few days before admission.

On examining the patient the sensorium was found to be very dull, associated with great prostration. The skin was icteric, and on the neck and extremities were small punctiform effusions. The lymphatics were swollen, the breathing dyspnoic, with 40 respirations in the minute, while both lungs had symptoms of pneumonia in both lower lobes. No apex beat of the heart could be detected, although its area was not enlarged, but the sounds were soft and clear; the pulse tension minimal and frequency 132. The abdomen had the liver greatly enlarged, the margin reaching the parasternal line somewhat below the level of the umbilicus, and the surface was smooth. The spleen was about three fingers breadth below the margin of the ribs, tender and of a soft consistence. The urine contained serum albumin and a large quantity of urobilin. Widal's reaction negative, and blood culture negative. The examination of the blood was more peculiar—hæmoglobin according to Sahli 20 per cent., erythrocytes 850,000. The leucocytes were examined from day to day, and never exceeded 1,000, their average being 880. The erythrocytes were irregular in size, poikilocytotic and slightly polychromic, few having nuclei and normoblasts. In the leucocyte preparations polymorphic nuclei and neutrophile were present in two preparations, but failed in others. The most prominent were small lymphocytes, but few mononuclear cells, no eosinophile, giant or myelocytes were present. Death was diagnosed as due to severe anæmia or leucopenia. Weichselbaum performed the autopsy, and found gangrenous periostitis around the left upper molar tooth, with necrosis of the alveola and a diphtheritic ulcer in the larynx. There was also confluent lobular pneumonia in the lower lobes of both lungs, and gangrene in the right upper lobe. Subacute enlargement of the spleen, with an anæmic infarct and degeneration of both liver and kidneys. There were also chronic endoarteritis of the aorta, petechiæ of the skin, and ecchymosis of the pericardium. The medulla of the bones in the upper limbs were red.

Here we have the origin of the sepsis in the periostium of a diseased tooth producing extreme anæmia and leucopenia, of which the other two were subsequently diagnosed. In 1904 Schwartz drew attention to an extreme case of leucopenia with the absence of the granulocytes. This was a child with a renal abscess, where bacterium coli and pus were present in the urine,

which Schwartz entirely eliminated from bone marrow interference, and believed it due to the lymphatics, although there was a possibility of a negative chemotaxis from the presence of the bacterium coli. The absence of a post-mortem fails to clear up this case. Another unusual observation is made by Türck, who has recorded a case of staphylococcus pyogenes aureus arising from the tonsils, septic endocarditis with a purulent embolus in the right lung. He found the blood with normal hæmoglobin and erythrocytes, but only 940 leucocytes; on the numeration plate only one polinuclearcyte could be found. The medulla of bone in the longer ones had a fatty appearance, while in the sternum it had a normal red colour. The microscopic examination showed the spleen and lymphatics to be normal, but the bone medulla had no granulocytes, but in their stead were found lymphocytes and plasma cells. This case nearly agrees in the leucocytes with the writer's own, the only difference being great anæmia with regenerative phenomena and a highly red appearance in the medulla of the long bones. He found giant cells in the blood, with chromatin and bulging of the nucleus and a non-granular protoplasm with eosinophile myelocytes, but no neutrophiles. In the spleen the principal change was in the pulpa, while there were no lymphocytes, but a large number of osseous non-granular giant cells with myeloblasts were found. In the lymphatics few lymphocytes were present, but a large number of myeloblasts were found with a few giant cells, while the liver had no giant cells, but a few radiating centres from acini proved the presence of non-granulated cells.

It is important to observe that the gums and teeth, which had produced a gangrenous periosteum was the probable result; but a large number of small round cells associated with large non-granulated ones, nowhere infiltration, is worthy of special notice, as there is strong objection made to the theory that gangrene can only be the result of infiltration from leukæmia.

Briefly stated, we have in this case hyperplasia in the marrow of long bones, increase of spleen, lymphatics, and liver as signs of leukæmia, but in the spleen and lymphatics there is an increase of myeloid tissue. Again, we have in the bone marrow large non-granular cells, while in the spleen and lymphatics the large granular cell of the marrow is found in its early stage.

A careful examination of the blood increases the difficulty of clearly demonstrating the lesion, but it is evident from the results that the erythrocyte and leucocyte apparatus are not injured in the same proportion, as the erythrocytes in the bone marrow are almost normal, while a large amount of blood pigment is to be met with in the spleen, pointing to destruction after manufacture, which is probably due to the septic toxin in the circulation. The presence of normoblasts in the blood, as well as in the bone marrow, supports this presumption of the bone marrow having its regenerative power entire. Our difficulty commences with the examination of the leucocyte, and how to reconcile the histological results of the bone marrow, spleen, and lymphatics. The granulated leucocyte is not to be found in the blood, which forces us to the conclusion that the functional apparatus of the granulocyte is also damaged by the same septic poison.

Türck relates two similar cases where the granulocytes were supplanted by myeloid cells, plasma cells, and lymphocytes, and no infiltration was present in any of the cells. In his second case, after treating with arsenic, leukopenia suddenly appeared in the form of chronic myeloid leukæmia, which finally assumed the form of acute lymphomitis with extreme leukopenia, whereby the granular cells fell to 6 per cent. According to Türck the bone marrow had lost the function of producing granulocyte, owing to a growth of lymphoid tissue, which is rather at variance with his histology of the cases. In our own cases the preparations will show that the myeloid tissue is abundant, but of a low type, from which a sort of giant myeloblast germinates, and may be correctly designated myeloid leukæmia, which is quite amenable to the Röntgen ray treatment, but as suddenly recurs as it disappears, the myeloblast reigning supreme. In this

sense it is possible that an intercurrent septic condition could be improved with the rays, but this presupposes the existence of a chronic leukæmia, which was not so in our cases, because in the qualitative analysis of the blood neutrophile polymorphic nuclei were exchanged for the myelocytes; besides, no symptom of the leukæmia existed before the sudden onset of the disease, nor could any sign be found in the subsequent examination. We are therefore forced to the conclusion that some deleterious infection suddenly acted upon and destroyed the granulocyte apparatus; subsequently, to accommodate the organism, a neoplastic tissue or hyperplasia of the bone marrow ensues which produces an immature cell and finally becomes established as a large or giant cell, that ceases to pass into the blood if the patient live long enough.

So far, this presumption is reasonable, but we must of necessity have varieties, and the first case quoted is a good example. There we had a staphylococcus infection that destroyed the function of the granulocyte in the bone marrow with the formation of the myeloid tissue, from which the myeloid cells had almost ceased to appear in the circulation, but to compensate for this deficiency a vicarious extra-medullary formation of the same tissue takes place in the spleen and lymphatic glands, from which the myeloid cells were thrown into the blood.

The question next arises: Is it the poison alone that damages the bone marrow, or is it a congenital or acquired weakness? Türck thought it due to a preceding illness in his cases, but that could not be advanced in our cases, as the inroad was sudden, and the specific granulocyte apparatus rapidly destroyed. Kelly is inclined to call the morbid condition a primary insufficiency of the bone marrow.

It must be admitted that the resisting power of the hæmatopoietic function differs in every individual, hence there must be some with a low power of resistance, which Ehrlich is pleased to call aplastic anæmia. The writer has recorded two of these aplastic cases this year, where the erythroblasts were absent, but myeloid tissue and atrophy of the lymphatics were present. The ætiology of one of these was from the tonsils, the second arose from the toxin of chronic dermatitis, which favours the view of congenital weakness in the hæmatopoietic system.

Morawitz found by experiments on dogs that he could produce morbid changes in bone marrow by repeated extractions of blood till the animal was exhausted, and the erythroblasts disappeared with the granulocyte while the lymph cells increased. By these experiments it was also proved that young animals had a greater power of regeneration than older. This is also noticeable in the human race, particularly after infectious diseases. This lower resistance may affect all the functions of the bone marrow, as in aplastic anæmia, or it may only affect a single cell group like the granulocyte apparatus, as in Türck's and our own cases. Histologically, anæmia and leukæmia are two different diseases, but the ætiology is the same, viz.: bacterial infection. The aplastic form of leukæmia is objected to by Pappenheim and Domarus, who maintain that Wolff's cases were only forms of medullary pseudo-leukæmia; while the cases we have presented here were really medullary aplastic leukæmia.

We may call it by any name that is most pleasing to the author, but enough has been proved to show that the origin is septic and acute in the hæmatic tissue. During the year we have had abundant testimony of such changes in the blood. Erb records streptococcus infection with large lymphatic cells and leukæmia. Eppenstein records acute lymphatic leukæmia from streptococcus sepsis. Ziegler and Jochmann, acute myeloid leukæmia from staphylococcus infection, etc., etc. All agree that a toxin is the cause of the leukæmia, and therefore is bacterial in origin.

This infectious origin is further illustrated in other infectious diseases where the myelocyte is found, such as pneumonia, scarlatina, erysipelas, meningitis, epidemica, typhus, malaria, etc., when myeloid changes are observed in the spleen and lymphatics. Myeloid metaplasia is another important change to be noted

in infectious diseases, where it seems the exhausted bone marrow demands some extra medullary assistance. After the infectious disease is past this extra function is unnecessary, and the extra medullary metaplasia disappears. Indeed, some authors now go so far as to support the idea of an infectious disease being the real cause of leukæmia, the latter being only the manifestation of the former. It cannot be affirmed, however, that the toxin is the ætiology, but it may have an injurious effect on the hæmatopoietic organ that may lead to leukæmia.

We may therefore conclude that it is uncertain what the agent or the cause is that produces the extra medullary metaplasia, or what reduces the active function in the bone marrow, with excessive growth of neoplasm which sends forth a quantity of pathological cells to enter the circulation. In leukæmia bacteria have been found which produce an alteration in the blood constituents in the shape of imperfectly formed cells ending in acute leukæmia. Some affirm the first change to be polynuclear leucocytosis which takes the place of the granulocyte, but in many cases this stage of polynuclear cells is lost and may be only transitory.

---

NOTE.—A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by A. F. Tredgold, L.R.C.P. Lond., M.R.C.S. Eng., Medical Expert to the Royal Commission on the Feeble-Minded; Consulting Physician to the National Association for the Feeble-Minded, &c., &c. Subject: "Feeble-Minded Children."

---

## ORIGINAL PAPERS.

### REGULATION OF MARRIAGE BY THE STATE. (a)

By S. A. BONTOR, M.D., M.S.,

Surgeon to the West Herts Hospital.

THE object of my paper this evening is to consider whether it is necessary, or advisable, for the legislature to introduce ordinances for the regulation of marriage, etc., in order to check the propagation and multiplication of the feeble-minded and degenerate.

The first question which arises in this connection is whether the matter is of sufficient importance to justify any legislation at all. We all recognise that there exists a certain proportion of those whom we group under the general term the "unfit," but are they not the inevitable product of the human wear and tear, the necessary detritus of the human machinery?

If we take humanity as it exists now it is undoubtedly on a much higher plane of moral and intellectual attainments than it ever has been before, and even from the physical standpoint there is, I believe, no decided evidence of any marked inferiority.

But it is not mankind in general—although to mankind the arguments I am about to bring forward would, *ceteris paribus*, apply with equal force—but our own nation in particular we must primarily consider. If we recall for a moment the history of the rise, progress, and fall of the various nations which have been pre-eminent in the past, we find that the same course has been experienced by each; there has been a period of hardship and energy accompanied by development, followed by a period of quiescence during the supremacy, and this has been succeeded by a decline and fall, a study of events during these periods showing us that it is by the interference by civilisation with the process of natural selection that the decline and fall is brought about. So soon as the necessity for striving and struggling is past there is no longer the extermination of the weaker members, and their proportion consequently steadily increases, until the standard of the whole country is lowered, and there is a diminution in the mental, moral and bodily

(a) Read before the West London Medico-Chirurgical Society, May 7th, 1909.

powers, and an increase in the numbers of those who are unable to fulfil properly the duties of citizenship, until finally there is a preponderance of these latter, and the doom of that country is sealed.

Now, how does this affect us? I say that we are travelling, and travelling fairly rapidly, in the direction of the fall. I do not wish to spoil a good case by over-zealous or special pleading, so in justifying this opinion I will confine myself to carefully ascertained and authoritative facts, and not indulge in generalities. I shall not employ vague terms such as "unemployable," "degenerate," "unfit," etc., nor will I deal with lunatics, the "dements," because the majority of these are under control and do not very largely add to the population.

The class which affects us most particularly is the class generally recognised as the mentally deficient, the "aments"; those who, in consequence of a state of mental defect at birth, or from early age, are unable to perform their duties as members of society in the position of life to which they are born. The majority of the members of this class is under no restraint and free to produce as many offspring as they please, and as a rule they are rather more prolific than the population in general, one observer—Dr. Potts—reporting that 16 mentally deficient women had actually produced 116 children, while another—Dr. Tredgold—reported that in Somersetshire of 167 feeble-minded women 61 had given birth to children and had produced between them no less than 158, these observations being confirmed by many others. Hitherto there have been no really reliable statistics as to the numbers of this class; their enumeration, for obvious reasons, is extremely difficult, and the figures which have until recently been relied upon are approximations only and are incomplete and unreliable. The extensive and recently issued Reports of the Royal Commission (1904) on the "Care and Control of the Feeble-minded," however, give us such elaborate and carefully compiled information that, so far as the "feeble-minded" are concerned, we may accept them as authoritative and trustworthy. From the statistics there given we are able to calculate that the total number of "aments" in England and Wales is 138,529, a number equal to 4.03 per thousand, or 1 to every 248 of the population.

As to whether this proportion is increasing or not we have not, for purposes of comparison, any equally reliable enumeration, but as Dr. Tredgold, who was one of the medical experts to the Royal Commission, has pointed out in his recently published "Mental Deficiency" (to which I am much indebted), the incidence of lunacy (dementia) and feeble-mindedness (amentia) very closely correspond, so that as the number of certified "dements" is accurately known, an estimation of the proportionate number of "aments" can be readily computed. Now, according to the Report of the Lunacy Commissioners, the number of lunatics on January 1, 1906, was 125,827, which is equal to 3.6 per 1,000, or 1 to every 273, but in 1859, less than fifty years ago, the proportion was 1 to every 536, so that the proportion of certified "dements" has practically doubled in fifty years, and it may therefore be accepted that the number of "aments" has, *pari passu*, increased in similar ratio. Further, it will be noticed that the proportion of the total number of persons suffering from all forms of mental deficiency is no less than 1 to 130—a state of affairs sufficiently appalling to justify, I think, my previous statement that this nation is approaching the fall, to call for the strongest efforts for its immediate amelioration, and to indicate the pressing necessity for the introduction of measures for the social control of those likely to increase this deficient population.

But, it may be said, such conclusions are based upon theoretical considerations. It is true that Mind is the predominant feature in Man, and that it is the faculty through which all human progress is regulated, but is there any practical justification for these theoretical considerations?

To meet this inquiry I have ascertained the capacity of our population for the public service in the Navy and Army, and I am informed (April, 1909) by the

First Lord of the Admiralty that no less than 40 per cent. of those who apply for service in the Navy are rejected by the recruiting petty officers for obvious defects before they are even submitted to the medical examiners; and from the last published medical report of the Army (1907) I find that, although the standard accepts men of 5ft. 3in., and a chest girth of 31½in., the proportion of rejections on medical grounds is as much as 30 per cent.

During the last few weeks the country has been thrown into a great state of excitement by the question of "Dreadnoughts," but of what value to the nation will the multiplication and improvement of our ships be, if nothing is done to check the degeneration of our men?

With these data before us, is not the conclusion forced upon us that no effort must be spared to find a remedy for so serious a complaint, and that we must find it as soon as possible? Before making suggestions in this direction, however, it will be well to consider what has been done by other nations in the matter. It is not necessary for our purpose to dwell upon the law of ancient times, such as those of the Spartans, nor to the proposals of Plato and Aristotle which were never acted upon, but to review only the enactments of recent days, the value of which we are able ourselves to estimate.

I cannot find that any laws or regulations directly bearing upon the subject have been introduced by any of the European countries, but in some of the States of the U.S.A. the serious position of affairs in respect of their own country has been appreciated, and several of them—Minnesota, Delaware, Michigan, Connecticut, New Jersey, North Dakota, etc.—have passed laws regulating marriage, while one (Indiana), in addition to a marriage law, has also adopted a sterilisation law "to prevent procreation of confirmed criminals, idiots, imbeciles, and rapists."

All of these laws have been passed within the last few years, Minnesota being the first in 1901.

I have here a copy of the marriage law of Indiana which was adopted March 6, 1905. It is "An Act regulating the issuance of licences to marry, prohibiting the issuance of such licences to certain persons, prescribing the duty of the clerk of the circuit court, and providing penalties for the violations of the provisions of this Act."

These provisions are couched in the appropriate legal phraseology, and I need not read them *in extenso*, but I will give a brief summary of them:—

"No licence to marry shall be issued except upon written and verified application. The form of application shall be supplied by the State Board of Health, and said Board may revise said form from time to time. No licence to marry shall be issued when either of the contracting parties is an imbecile, epileptic, of unsound mind or under guardianship as a person of unsound mind, nor to any male person who is, or has been, within the last five years an inmate of any county asylum or home for indigent persons, nor shall any licence issue when either of the contracting parties is afflicted with a transmissible disease.

"The marriage is illegal without a licence, and a penalty of \$100 fine lies against any county clerk for issuing a licence contrary to law, and the same penalty lies against any person authorised to marry who does so when the applicant has no licence."

I have here also copies of the marriage licences for male and female.

The sterilisation law of the same State, which was adopted in 1907, being of a novel character and of brief dimensions, I will read it:—

"Whereas heredity plays a most important part in the transmission of crime, idiocy, and imbecility, therefore be it enacted by the General Assembly of the State of Indiana that on and after the passage of this Act it shall be compulsory for each and every institution in the State, entrusted with the care of confirmed criminals, idiots, rapists, and imbeciles to appoint upon its staff, in addition to the regular institutional physician, two skilled surgeons of recognised ability, whose duty it shall be, in conjunction with the chief physician of the institution, to examine the

mental and physical conditions of such inmates as are recommended by the Institutional Physician and Board of Managers. If, in the judgment of this Committee of Experts and the Board of Managers, procreation is inadvisable, and there is no probability of improvement of the mental conditions of the inmate, it shall be lawful for the surgeons to perform such operation for the prevention of procreation as shall be decided safest and most effective. But this operation shall not be performed except in cases that have been pronounced unimprovable."

The law, you will notice, applies to male and female alike, and to idiots, criminals, imbeciles, and rapists. It does not apply to the insane; it is, indeed, unnecessary, for once a person has been placed in an insane asylum he very rarely comes into the open world again.

I have been at some pains to ascertain from men on the spot the efficiency of these laws in attaining their object, and I find there appears to be some doubt. Thus Dr. Hurty, the Secretary of the State Board of Health of Indiana, writes me: "The laws are being enforced, and are certainly producing good results. They have been in operation for only a short time, and therefore we have as yet no actual figures to present, but we do know they are preventing, in Indiana, the marriage of people who are unfit to marry."

Mr. Butler, the Secretary of the Indiana Board of State Charities, in reference to the marriage law, says: "Just how much good this has done I am unable to tell you. In some counties it is strictly enforced and in others it is not. At any rate, it has prevented some undesirable persons from getting married. Its administration now is largely a matter of education, and we believe will be quite beneficial."

Dr. Belfield, President of the American Urological Association, writes: "The prohibition of marriage among the unfit has been enacted, with varying details, by at least a dozen of our States. Such legislation has had virtually no value except to emphasise the necessity for more effective measures. In some of these States the laws appear to have been dead letters from their inception; in other States the laws have simply increased the sum total of official falsehood, and of bastardy among the irresponsible unfortunates. I think it may be accepted as proven that legislation intended to restrict marriage among the judicially unfit has not appreciably restricted propagation by these classes."

The operations usually performed for sterilisation are salpingectomy in the female and vasectomy in the male.

Vasectomy, which is performed by making a small incision in the scrotum, hooking up the vas deferens, and excising about half an inch of it without ligaturing it, is of course a simple little matter to carry out. It requires, according to Dr. Sharp, about three minutes to perform, and the subject returns to his work immediately, or at the most has one day off; he suffers practically no inconvenience, and he is in no way impaired for his pursuit of life, liberty, and happiness; but is effectually sterilised. One man, a phthisical patient, is reported to have had sexual intercourse within forty-eight hours of the operation and to have been perfectly contented and happy. After an experience of several hundred cases, which have afforded splendid opportunities for post-operative observations, Dr. Sharp says he has not seen an unfavourable symptom, and "there is no atrophy of the testicle (I may here remind you that this operation was originally introduced for the very purpose of producing atrophy of the testicles in cases of enlarged prostate), no cystic degeneration, there is no disturbed mental or nervous condition following, but, on the contrary, the patient becomes of a more sunny disposition, brighter in intellect, and advises his fellows to submit to the operation for their own good. And here is where this method of preventing procreation is so infinitely superior to all others proposed—that it is endorsed by the persons who have been subjected to it."

Salpingectomy, which I describe in the words of Dr.

van Meter, of San Francisco, is of course a more serious matter, as it involves an abdominal section, but except for this is quite simple. He says: "I make a small slit through the peritoneal covering of the tube, at its proximal end, and hook up the oviduct and sever it at its uterine juncture, reflecting the severed end on the distal side, out through the incision in the peritoneal covering, and closing the incision with two or three stitches of fine catgut."

There is thus in both cases no destruction, not even disturbance of the nerves and blood-vessels supplying the structures, hence positively and absolutely no interference in any way with the physiological functions normally performed.

Dr. van Meter has performed the operation of salpingectomy for preventing heredity on about one hundred women, and he says: "Now I fully believe that when the people are convinced that an operation can be done that will prevent the begetting of degenerate offspring they will be ready for such a law as the Sterilisation Law, and will compel choice between submission to such operation or remaining single. And such law would be more easily passed than a law which would entirely prohibit the marriage of persons whom a board of examiners might pronounce unfit."

Dr. Sharp, who has performed the operation of vasectomy in about 500 cases, says: "Restricting propagation seems to be universally agreed upon as necessary for the relief of the responsibility of imposing hereditary taints upon the offspring," while, as to the effect of the marriage laws, he expresses the following opinion: "Marriage is not always necessary to procreation, and the tendency of these different laws is to restrict propagation only among the more moral and intelligent class, while the most undesirable class goes on reproducing its kind, the only difference being that illegitimacy is added to degeneracy."

From a review of these opinions it is very obvious that the framing of suitable regulations is no easy matter, indeed, is so great a task that the only possible method for it to be successfully accomplished is by the carefully considered opinion of a competent committee, specially appointed for the purpose. Consequently, I have not come prepared with a cut and dried scheme to put before you; I should, however, like to offer a few observations and criticisms.

In the first place, there appears to be a unanimity of opinion that a step has been made in the right direction, but that marriage laws are not of very much use by themselves, and I quite agree with this. Marriage is an established custom of the greatest antiquity, and is one of the most important institutions of human society. It is so surrounded by sentiment, is so personal, and involves so deeply the right of the individual to select for himself his mate, that any new legislation must be so wisely framed and on so broad-minded a basis that the liberty of the subject may be jeopardised as little as possible, while the ordinances which are enacted must contain only such provisions as are likely to be accepted by the majority. But the majority, it would appear from the opinions of the American observers which I have given, are not yet prepared to accept these laws, and therefore our first endeavour must be to form a conscience of the community, to educate public opinion, and this, though difficult, should prove to be not an insuperable task.

There is no doubt that public opinion is a great force, capable of exerting enormous power, and there is equally no doubt, in my mind, that if the importance of this subject can be made generally recognised that many customs will be introduced and that many social influences will be brought to bear which will eventually render easy of accomplishment those measures which, at the present time, might possibly be met with all the resistance of the enormous power public opinion is capable of exerting.

The ground, however, is already somewhat prepared for us. When a marriage is contemplated, not only is the wedding clothing considered, the wedding feast prepared, and the guests bidden to it, but the hygienic conditions of the future home of the newly united pair

is taken seriously into consideration, the soil on which it stands, its aspect, water supply, its drainage, etc., are inquired into as a matter of course. Is it then not reasonable to expect that the far more important consideration, the very object for which the marriage has been consummated—the procreation of children—should receive at least the same serious consideration?

Further, such splendid results have accrued to the scientific efforts which have been made in the improvement in the breed of our cattle, our horses, our dogs, and even our vegetables, that it probably would require but little effort to induce the acceptance of public opinion of the necessity for the application of similar rules for the improvement of the human breed, and, therefore, the introduction of laws for the regulation of marriage would probably be favourably received by many even now; it would only be regarded as the addition of another of the hygienic ordinances, like those relating to sanitation, vaccination, etc., the value of which are now generally appreciated; indeed, several instances of inquiry into the matter by those contemplating marriage have already come to my notice. But even if marriage laws were introduced now, and willingly accepted and acted upon, would this be sufficient? I am afraid not. Most of the American observers seem to be of opinion that, unsupported by further measures, such laws would not be very far-reaching; some even suggest the aggravation of moral degeneracy "by the increase of official lying and bastardy." The former needs no consideration here, but as regards illegitimacy I doubt whether this opinion is correct for this country—the number of illegitimate children already produced, by the women of this degenerate class, is shown by the Reports of the Royal Commission to be at the present time so great that I believe marriage laws could be framed which would reduce, rather than increase, the number of bastards; but such laws would have to embody the provision of some physical means to be employed to prevent the propagation of these unfortunate members of our society. To say that they shall not marry is not sufficient; there are some persons of whom it may safely be predicted that they will beget deficient offspring; surely it would be better for these that they should have the companionship of a mate—only they must not be allowed to produce children to perpetuate their disabilities.

It is here, however, that the education of public opinion will be most difficult, but I believe it may be induced by convincing every intelligent man and woman of the danger of alliance with families vitiated by degeneracy; there is already a general acceptance of the opinion that lunacy, phthisis, etc., are an impediment to marriage, and therefore a general appreciation of the awful responsibility involved in the propagation of the less severe forms of mental deficiency should not be difficult to bring about; already I believe that many intelligent men would prefer to be sterilised, by such a method as I have described, than run the risk of imposing such hereditary taints upon their offspring; but while this is possible of the intelligent members of society the laws would have to be enacted for that portion to whom argument would be of little or no avail—in fact, for them it would have to be, "Be sterilised or you cannot marry," that is to say, compulsory sterilisation, and for this I feel that English sentiment may not yet be prepared.

But for us of the medical profession, with our increased appreciation of the physical side of life, our greater recognition of the importance of the laws of heredity, and how civilisation interferes with the beneficial influence which natural selection exercises upon the stability of our race, and our knowledge of the relation between marriage on the one hand, and health and disease on the other, the adoption of the principle of sterilisation should not be so difficult. Not only should we denounce to the utmost of our power the unrestricted marriage of the diseased, the degenerate, the criminal and the pauper, but we should also strongly protest against legislation or the want of legislation, which permits to those irresponsible people the production of as many offspring as they see fit to produce. To-day the individual dominates more than he has ever done before, and a population compara-

tively small numerically, but of highly developed individuality, would be of far greater value to the nation than a degenerate population even vastly superior in numbers.

I have shown that a rapid disintegration of our national strength is taking place. Now I would ask, Is nothing to be done to check it? Unless something is done it can only be a question of time for the doom of other great nations to overwhelm us.

The whole question is a difficult one without any doubt, but that is only an additional reason for facing it boldly, and that is why I have ventured to bring the subject before you this evening. I have tried to do so as temperately and logically as possible—but I do not forget that the World is not ruled by Logic. I do hope, however, that I have said enough to convince you of the urgent need for some action in the matter, and that every one will leave this room feeling the necessity, not only to recognise the evil, but to regard it as a solemn duty to preach the gospel of national supremacy; and, further, that when he sees a "degenerate" he will not regard him with an eye of pity as the inevitable product of civilisation, but rather look upon him as the text upon which his sermon may be based.

## THE ÆTIOLOGY, DIAGNOSIS AND PROPHYLAXIS OF ENTERIC FEVER IN INDIA. (a)

By LIEUT.-COL. D. SEMPLE, M.D., R.A.M.C. (RET.).

Director, Central Research Institute, Kasauli, Punjab.

BEFORE intelligent and successful measures can be adopted in connection with any infectious disease, it is necessary to know what is the agent which gives rise to the disease, where the store-house of the causal agent is to be found, and the means by which susceptible persons get infected; or in other words, what is the infection? where does it exist? how is it kept up? how is it conveyed? A few leading facts of this nature lie at the root of all scientific preventive measures which are applicable to infectious diseases, and more especially to enteric fever. In 1880, Eberth first recognised the bacillus typhosus as the causal agent of typhoid fever, and a few years later Gafky was able to obtain the germ in pure culture from the spleen, the liver, and the mesenteric glands of patients who had died of the disease. For over 20 years, matters remained practically at this stage, with the exception that a few more facts were added to our knowledge of the distribution of the bacillus in the tissues, secretions, and excretions of patients, until Koch in 1902-3 solved the problem of the store-house of the virus. In conjunction with French and other workers, he proved that a percentage of those who had passed through an attack of enteric fever continued to harbour the parasite for prolonged periods, excreting it either in their faeces, or urines, or in both. He found that not only was this the case in those who had passed through a typical attack of the disease, but that it might also occur after the slightest form of infection, or where the disease had passed unrecognised. He also proved that saprophytic existence of the bacillus outside the body of man is comparatively short. The conclusions he arrived at from these two important facts were, that man was the store-house of the bacillus in Nature, and that susceptible persons were infected either directly or indirectly from this source alone. The work initiated by Koch was confirmed by Lentz, Conradi, Kayser and others. To these workers we are indebted for most of our knowledge of the early facts about bacilli carriers. They proved that chronic carriers are sources of infection to the community, and that they may continue intermittently to disseminate infection for months or years. About the same time, several other important facts came to light, such as the demonstration of the bacilli in the blood early in the disease; improved methods of cultivating *B. typhosus* from the blood and dejecta:

(a) Read at the Bombay Medical Congress, 1909.

the isolation of the bacillus from the excretions of healthy persons with no history of enteric, but who had been in contact with enteric cases, or who had lived under conditions where infection was possible.

The knowledge of these new facts served as a sound basis upon which to build up scientific preventive measures, and so prevented waste of useless energy in other directions.

Man alone being susceptible to a virus which is short-lived outside the human body, the disease can only be kept up by being passed on from man to man. The channels by which this transference is accomplished are numerous, but broadly speaking they all resolve themselves into the fact that a susceptible person swallows the causal micro-organism in contaminated hands, flies, and other articles coming in contact with his mouth, food, or drink. A campaign against enteric fever can prove successful only when measures are directed against the sources of infection, *viz.*, the enteric fever patient and the bacilli carrier.

#### THE CAUSAL MICRO-ORGANISMS.

By enteric fever is generally meant an infection caused by the bacillus typhosus of Eberth, but within the past few years the term has come to have a wider meaning, and it is now used to comprehend an infection which may be caused by any one of a group of bacilli more or less allied to each other.

1. *B. typhosus* of Eberth, the causal agent of typhoid fever.

2. *B. paratyphosus* A. (Brien and Kaiser) and *B. paratyphoid* B. (Schettmuller), the causal agents of paratyphoid A. and paratyphoid B. respectively. In addition, a fever, clinically indistinguishable in its later stages from enteric fever may be caused by any one of a group of other bacilli connected with meat-poisoning, and more or less allied to the paratyphoid group. The known bacilli of this group are Gaertner's bacillus, and the enteritidis bacillus. (Flugge Kaensche) : the former of these is identical with the rat pathogenic micro-organism of Dunbar, Danyasz and Isatzcheuke, and the latter with the hog cholera group. A differentiation of the infecting agent can only be arrived at by bacteriological methods of diagnosis. Clinically it is not possible to differentiate between typhoid and paratyphoid infections. In all these infections the infecting agent is found in the blood at some period of the illness, possibly during the whole of the fever period. By far the greater majority of cases of enteric fever are caused by the *B. typhosus* of Eberth, and would therefore come under the heading enteric fever. The proportion of cases of paratyphoid varies according to different observers from 3 per cent. to 10 per cent. At the Central Research Institute, Kasauli, we met with 6 cases of paratyphoid in the investigation of 91 cases of enteric fever in which the causal micro-organism was isolated; of these cases, 4 were caused by *B. paratyphosus* A. and 2 by *B. paratyphosus* B. One of the paratyphoid A. cases was a mixed infection, as the *B. typhosus* of Eberth was also isolated from this case. With the exception of the wider distribution in nature of the paratyphoid micro-organisms, facts applicable to typhoid apply equally to paratyphoid infections.

#### THE RELATION OF THE CAUSAL MICRO-ORGANISM TO INFECTED PERSONS.

*During an attack of the Disease.*—At some period of the fever (probably during the whole of the fever period) the infective agent is found in the blood, and can be cultivated from it in suitable media. The specific virus when swallowed is taken up by the lymphatic tissues of the digestive tract where it commences to multiply; soon it finds its way to the mesenteric lymph glands, where further increase occurs, and from these situations it is passed on to the blood stream, when the disease becomes a bacteraemia. Inflammation of the tonsils and fauces being a common symptom shortly before, or during the early stages of enteric, it is very possible that the virus in some cases gains an entrance *via* the lymphatic tissues

of the tonsils. Through the medium of the blood the bacilli are lodged in the liver, spleen, kidneys, and bone marrow, and form foci of multiplication in these situations. The excretory passages of the bile and urine get their infections from the liver and kidneys respectively. Typhoid and paratyphoid bacilli grow well in bile and urine. From the gall-bladder the bacilli are excreted into the intestinal tract with the bile, and mix with the intestinal contents, where according to Lentz (a), they do not multiply, but are liable to perish.

In 42 samples of bile received at the Central Research Institute, Kasauli, from various parts of India and taken from *post-mortem* cases diagnosed enteric before death, *B. typhosus* was isolated from 27, which gives a percentage of 64.3. Many of the samples received were grossly contaminated with *B. coli* and other micro-organisms which may have killed off the *B. typhosus* in many of the samples during transit. We rarely find Eberth's bacillus in the faeces during the early stages of the disease. When several examinations are made after the 10th day, they have been found in 80 per cent. of cases, but with only one examination the percentage of positive results would not be over 30 per cent., possibly as low as 15 per cent. Early in the disease cultivations from the urine seldom give positive results, but after the 3rd week, the positive results would vary from 25 per cent. to 30 per cent. Wright and Semple (b) in 1895 drew attention to the urine as a potential source of infection in patients suffering from enteric fever. They isolated the bacillus from the urine and rose spots of a series of cases at Netley and Southampton, and utilised the fact of the presence of infection in the kidneys, urine, and rose spots as an argument in favour of the disease being a septicaemia.

The frequency with which the bacilli are found in the blood depends on the stage of the disease when cultivations are made, and on the medium employed. Examinations made during the first and second weeks give a higher percentage of positive results than those made later on. Stuhlern (c) examined 30 cases of enteric fever and made cultivations from the blood every 3 to 4 days during the fever period. He found the bacillus in every case, and in greatest number during the early stages of the fever. As the disease progressed the bacilli became fewer and fewer, and finally disappeared when the temperature reached normal. At the Central Research Institute, Kasauli, cultivations were made from the blood of 49 cases of enteric fever among Europeans, one cultivation from each case. The stages of the disease at which blood was taken varied from the 1st to the end of the 3rd week, but most of the examinations were made during the 2nd week. Typhoid bacilli were found in 32, which gives 65.3 per cent. Of the 17 negative cases, typhoid bacilli were subsequently isolated from the dejecta of 10, and remaining 7 gave a well-marked Widal reaction on *B. typhosus*. In another series of 15 cases of enteric fever among natives, in which the disease was diagnosed bacteriologically, cultivations were made from the blood of 10, one cultivation from each case. The stages of the disease at which blood was taken in those 10 cases varied from 1st to the 3rd week. Typhoid bacilli were found in 5, and *B. paratyphosus* A. in one, which gives 60 per cent.; of the 4 cases in which cultivations from the blood gave negative results, typhoid bacilli were subsequently isolated from the dejecta of 3, and the 4th gave a Widal reaction 1 in 400 on *B. typhosus*. In the remaining 5 cases in which no attempt was made to cultivate from the blood, typhoid bacilli were isolated from the dejecta of all five. The bacilli are sometimes found in the lungs, and may give rise to symptoms of bronchitis or other symptoms. On this account expectoration from an enteric patient may

(b) Wright and Semple, on the presence of typhoid bacilli in the urine of patients suffering from typhoid fever. *Lancet*, July 27th, 1895.

(c) Stuhlern, *Central fur Bakt.*, July 31st, 1906.

convey infection. The bacilli are invariably present in the rose spots. The fact of the disease being a bacteræmia would lead one to expect to find the causal agent at times anywhere in the body. When the infection continues to multiply in the gall-bladder, or urinary passages after convalescence the patient becomes a "bacilli carrier."

*The relation during Convalescence.*—As soon as the acute clinical symptoms subside and the temperature approaches normal, the bacilli disappear from the blood, and convalescence sets in, unless it is interfered with by complications or a relapse. In the great majority of cases, shortly after convalescence has been established, the patient is free from infection. In a certain proportion of cases, however, the result is not quite so satisfactory, for it has now been proved that the infection may continue to cultivate itself in the biliary and the urinary passages during convalescence, and in a smaller proportion of cases it may continue to do so for weeks, months, or years after the convalescent stage has been passed. In these latter cases the patients are known as "bacilli carriers." It is evident from this and also from the fact that post-typhoidal abscesses occur, that recovery from enteric does not necessarily mean destruction of all the bacilli in the body. It is important to remember that during the later stages of the disease and during convalescence, the bacilli may be present in the urine in enormous numbers; as many as 100,000,000 per c.c. have been found in the urine of a case investigated at the Central Research Institute, Kasauli, and several times in this patient and in others the number varied from 1,000,000 to 90,000,000 per c.c. As urine is a suitable medium for *B. typhosus*, these enormous numbers are easily accounted for.

*Bacilli Carriers.*—Bacilli carriers are recruited from two classes of the community.

1. A percentage of persons who have passed through an attack of enteric fever, but who still continue to harbour infection excrete it in their faeces or urine.
2. A proportion of those who have been in close contact with the disease, or who have lived under conditions where infection was possible, but who have not passed through an attack of the disease in a clinically recognisable form.

The Germans make a distinction between acute (or temporary) and chronic carriers.

1. Acute or temporary carriers are those who harbour infection only for a few weeks, and, in the case of convalescence, enteric patients, for a period up to 6 weeks after convalescence has been established.
2. Chronic carriers are those who harbour infection for months, or years, and in the case of enteric convalescents, for periods longer than 6 weeks after convalescence has been established.

In both classes the gall-bladder or the urinary passages are the sources from which the infection is derived. The infection of the biliary and the urinary passages does not depend upon the severity of the disease. The mildest types of enteric fever are just as likely to give rise to bacilli carriers as the severest form of the disease. Absence of any symptoms pointing to their condition, and the intermittent excretion of infection, are the most noteworthy facts about carriers. It is only possible to detect these persons by means of a careful and skilled bacteriological examination of their faeces and urine, but owing to the intermittent excretion of infection this examination may have to be repeated daily for a prolonged period before any definite conclusion can be arrived at. In a number of cases in which the urine and faeces were examined daily at the Central Research Institute, Kasauli, the longest "bacilli free" interval in the faeces was 75 days, and in the urine, 31 days; In several cases the faeces were free from infection for periods varying from a few days up to 2-3 weeks. In others the urine or faeces were infected daily for a week or 10 days without an interval. The bacilli carriers are a potential source

of infection, and have in many instances caused outbreaks of enteric, has been proved beyond a shadow of doubt, and is now an accepted fact; but whether they are a fruitful source of infection or not, depends altogether on the facilities they have for infecting food, milk, or drink supplies, or coming into contact with susceptible persons.

As regards the percentage of enteric convalescents who become bacilli carriers, Klinger mentions 1.7 per cent., and Lentz 4 per cent., other observers think those figures too low. 86 convalescent enteric soldier patients were examined at the Central Research Institute, Kasauli (a), during 1906-7, and ten were found to be excreting infection for periods longer than 6 weeks after convalescence. This gives 11.6 per cent. of cases infectious for longer than 6 weeks after convalescence. Some of these continued to excrete the bacilli in their faeces or urine for months. Two of them were followed up for a year and found to be still infectious, and these two cases may go on for a number of years to come. In a campaign against enteric the detection of bacilli carriers is of the utmost importance, but unfortunately it is as yet a very difficult problem. What is wanted is a quick and accurate method of detecting these cases, and, when they are detected, safe and practical methods of rendering them permanently innocuous. The solution of those two problems will mark the next most important advance in the prevention of enteric fever.

#### BACTERIOLOGICAL METHODS EMPLOYED IN THE DIAGNOSIS OF ENTERIC FEVER.

The methods which have proved of most practical value are cultivations from the blood, and the serum test. Both are easy of application, and may be carried out by any medical man with a knowledge of bacteriological technique. In a few cases it may be necessary to fall back upon examinations of the faeces and urine, and in *post-mortem* cases it is sometimes necessary to prove or disprove a doubtful diagnosis by making a cultivation from the gall-bladder, the spleen, or other internal organs. In the detection of bacilli carriers, cultivations from the dejecta are absolutely necessary.

(a) *Blood Cultures.*—This method is of most value early in the disease, and a positive result may be obtained before Widal's reaction is present. The media employed are numerous and varied. The best results have been obtained by Conradi's (b) medium which is ox bile, plus 10 per cent. glycerine and 10 per cent. peptone. Kayser (c) used ox bile only. Epstein (d) claims to have obtained a higher percentage of positive results with any one of the following media:—

2 per cent. glucose agar; 2 per cent. glucose bouillon; 0.2 per cent. ammonium oxalate solution. The reaction of these media ought to be 0.9 per cent. acid to phenolphthalein. One or other of the media mentioned has gradually displaced plain bouillon which was formerly used.

The special advantages of the bile media are supposed to be their inhibitory action on the coagulation of the blood, and the consequent preventive action of its bactericidal powers, also the influence of the bile salts in retarding the growth of certain other bacteria. My experience has mainly been with Conradi's bile medium. Into a small flask, bottle, or large test tube containing 20 or 30 c.c. of the sterile bile medium, is inoculated a few c.c. of blood drawn off by means of a sterile syringe and under aseptic precautions, from a vein of the arm in front of the elbow, generally the medium basillæ. One c.c., or even a few drops, would probably be sufficient in many cases, but as a routine measure from 2 to 5 c.c. is recommended. Another method which is said to answer very well, is to prick the lobe of the ear, and allow a few drops of blood to fall into a test tube containing whatever medium is

used. The medium containing the blood is then incubated at 37 deg. C. for 16 to 24 hours, and a subculture made on to agar, or Drigalski-Conradi plates, when a pure culture is obtained in the majority of cases yielding positive results. It is difficult to detect or stain the bacilli in a bile glycerine medium, hence the necessity for a subculture. The advantage of subculturing on to Drigalski-Conradi medium is that the colonies of typhoid or paratyphoid have a characteristic appearance on this medium, and can be easily detected for test purposes.

One of the most useful tests at this stage is the serum test. A colony from a Drigalski-Conradi plate, giving the delicate clear bluish transparent appearance of a typhoid or paratyphoid colony, can be easily picked out with a platinum needle, and mixed on a glass slide with a high titre specific serum in a suitable dilution, when an immediate clumping reaction takes place, which may be visible to the naked eye, or can be rendered visible by a hand lens, or under a microscope. At the same time one could test for motility, and stain a specimen. A motile bacillus, not retaining the stain when treated by Gram's method, giving a colony on Drigalski-Conradi medium, presenting the characters above described, and reacting to a specific serum, is sufficient for a quick diagnosis. Cultivations made by numerous observers on the lines above described give from 80 per cent. to over 90 per cent. of positive results during the 1st and 2nd weeks of the fever, and diminishing percentages during the later stages, until the bacilli finally disappear about the time convalescence sets in.

(b) *Widal's Reaction*.—This test requires no special description, as it is well known to most medical men. The reaction is rarely found during the 1st week, and may be absent during the second and third weeks, and in exceptional cases may not be found until convalescence sets in, or possibly not at all. In typhoid infections the serum may also agglutinate paratyphoid bacilli, and *vice versa* (group reactions); but as a rule the serum reacts in higher dilutions on the causal micro-organism. To this rule there are exceptions, and it is in these exceptional cases that a positive blood culture makes clear the nature of the infection. In some cases of jaundice the serum reacts on *B. typhosus*; and, of course, a reaction may be found for a variable period in those who have had an attack of enteric, or who have been inoculated against it. Notwithstanding these pitfalls, and others which might be mentioned, such an unreliable test culture, Widal's reaction properly interpreted is a most valuable aid in diagnosing enteric, especially in later stages of the disease. In blood cultures combined with Widal's reaction we have accurate means of diagnosing enteric in almost every case.

(c) *Cultivations from faeces and urine*.—Samples should be obtained as fresh as possible, and cultivations made without delay. A very good medium to use is the Drigalski-Conradi medium, but several other media have given good results, notably MacConkey's and Endo's. Conradi (a) has recently brought out a new medium for the detection of *B. typhosus* when present in small numbers. It consists of 3 per cent. agar to which is added picric acid and brilliant green crystal extra pure (Hochst). Both are acid dyes. The former is used in a dilution of 1 in 15,000, and the latter in a dilution of 1 in 150,000. The degree of acidity of the agar must be 3 per cent. Conradi states that a combination of these two dyes in the proportions mentioned, when added to agar, furnishes a medium which does not prevent the growth of *B. typhosus*, but at the same time has a strong inhibitory action on the growth of other organisms; after incubation for 24 hours at 37 deg. C. on this medium *B. typhosus* grows in small round colonies with smooth edges and almost flat. It is well to dilute the faeces before plating out. A convenient method of doing this is to emulsify one or two grammes of faecal matter in a conical glass vessel with 10 or 20 c.c. of sterile normal salt solution; when the emulsion has stood for about

one hour, so as to allow the coarser particles to subside, a small quantity of the supernatant fluid is pipetted off for plating. It is necessary to use 3 large Petri dish plates for each case, about 1 c.c. of the fluid emulsion is transferred to plate 1, and carefully spread over the surface with a glass rod spreader bent at right angles. The same spreader, but without being reinfected, is then carefully rubbed in succession over the surface of plates 2 and 3; all three plates are then incubated at a temperature of 37 deg. C. for 24 hours.

The next step is to search for colonies resembling typhoid or paratyphoid, and when any are found apply the usual tests.

The whole process is very easily carried out, but it requires considerable practice before one is able to detect the colonies with accuracy. It is very easy to miss a few typhoid or paratyphoid colonies mixed up with a rich growth of other bacteria found in faeces.

From urine it is only necessary to spread a small quantity of the urine varying from a few drops to 1 c.c. or thereabouts, over the surface of a Drigalski-Conradi plate, and incubate for 24 hours, and apply the usual tests to suspected colonies.

(d) *Cultivations from the gall-bladder or internal organs after death*.—Media similar to those employed in isolating the bacillus from the blood can be used. As regards the bile, it is only necessary to withdraw a little of this fluid from the gall-bladder, and spread it over a Drigalski-Conradi plate. A portion of the spleen, the liver, or the kidneys might be emulsified in normal salt solution and spread over a Drigalski-Conradi plate; or a small portion might first of all be transferred to Conradi's bile medium, and after incubating for 24 hours at 37 deg. C. subcultures could be made as already described in the case of isolating the bacillus from the blood.

(e) *Sources of infection*.—The recognition of the fact that man is the storehouse of infection lies at the root of the ætiology of enteric fever.

Those who harbour infection may be divided into four classes:—

1. Persons suffering from enteric fever diagnosed and treated as such.
2. Persons suffering from enteric fever but not diagnosed or treated as such. This class would include mild attacks in which the true nature of the disease was not suspected; and possibly many cases diagnosed and treated as ordinary diarrhoea or simple continued fever.
3. Convalescent enteric patients who have become "bacilli carriers."
4. Healthy persons who have never so far as we know passed through an attack of the disease, such as attendants on enteric fever cases, or persons who have been subjected to the same opportunities of infection as those who contracted the disease; probably temporary harbourers of infection, infective but not infected in the ordinary sense of the term.

Class 1 is the most dangerous, owing to the fact that the disease has been recognised. The remaining three classes may be looked upon as the real propagators of the disease in India, especially class 3.

(f) *Channels of Infection*.—In epidemics, a common source of food, water, or milk supply are the usual channels by which the infection is conveyed. In endemic cases, contact infection plays the most prominent part, and next in importance comes the contamination of food, milk, and drink supplies. Of these food and drink supplies, milk is perhaps the most important, and water for drinking purposes in India is of secondary importance. The opportunities for spreading infection are numerous in the cases of harbourers of the virus who have anything to do with the preparation or handling of food or dairy supplies. Cooks, bakers or dairy men who happen to be bacilli carriers were perhaps the most dangerous people of all, on account of the opportunities they have of handling media suitable for the dissemination of infection. In crowded camps, and where the disposal of infected excreta and other sanitary measures are difficult to carry out, flies may convey infection, but under ordinary conditions of life it is questionable whether

these agents account for even a small percentage of cases.

(g) *Preventive Measures*.—Any sound methods of prevention must take into account the sources from which the infection is derived, *viz.*, *enteric fever patients*, and *bacilli carriers*. Methods of prevention which fail to take these sources into consideration can end only in failure and disappointment. It is necessary to find out and isolate all those who harbour infection, and with this object in view particular attention should be paid to accurate method of diagnosis; to chronic carriers; and to those who live under conditions where infection may be expected. Before convalescent enteric patients are discharged from hospital or the sick-room, steps should be taken to ascertain whether they are free from infection, and any who are found to be infective should be detained until a definite conclusion has been arrived at as to whether they have become bacilli carriers.

Bacilli carriers should have their conditions explained to them, and they should be warned of the importance of cleanly habits. Disinfection of their excretions should be insisted on. On no account should they be employed in the preparation or handling of food, milk or drink supplies. In a word they should be debarred from any kind of work which gives them opportunities for infecting other people. At present we know of no safe and reliable method by which a bacilli carrier can be freed from infection. As regards hygienic measures, a scientific method of sewage disposal and a pure water-supply are the most important.

(h) *Prophylactic Inoculation*.—Prophylactic inoculation is strongly recommended for Europeans of the susceptible age period. It is especially applicable to young officers (Military and Civilian) and young soldiers on proceeding to India for their first tour of service, and it should be carried out shortly before or immediately on their arrival in the country.

## THE ORIGIN OF INFECTIOUS DISEASES. (a)

BY ALBERT S. ASHMEAD, M.D.,  
New York.

DR. JONES is in error here, for no less an authority than Virchow has said that "syphilis was in Western Europe as early as 1472." The "Maderlienes" (leper burying grounds), eleventh, twelfth, and thirteenth centuries, of France were found by Dr. Raymond, of Paris, to be filled with syphilitic bones. The *chullpas* and *chaukallas* of Huarochiri province, Peru (ancient cavern burial-places) of the Yauyos Indians (pre-Aymaran), show, it is true, many syphilitic skulls, as shown by Tello, who has excavated a majority of their tombs, and exhumed 15,000 crania and mummies, 500 of which skulls were trepanned, and most of them, showing processes of repair—evidences of pre-Columbian syphilis. These evidences were exostoses of frontal, parietal, and occipital bones; gummos lesions of fronto-parietal regions; gummos osteomyelites, osteo-periostites (gummos and diffuse of parietals and occipitals); and extensive corrosive lesions and circumscribed gumma of the frontal bones.

Pruden has found lesions similar to those produced by syphilis in pre-Columbian bones from Kentucky. I myself described a skull, of the Bandelier collection, from Peru, showing operative interference for syphilitic lesion.

Moreno, of Buenos Aires, showed in the Anthropological Society of Paris prehistoric crania from Patagonia, which had syphilitic osteitis. Some of Tello's skulls were dug from a depth of 2 metres. The Aymaran and Incan used the same word for syphilis, *huanthi*, which is undoubtedly Aymaran. Therefore, the Incans probably received the infection from the Aymarans, who had possessed the soil before their conquest. The Yauyos Indians used this same word, an Aymaran one. Anciently the symbol for syphilis was a snake represented eating the penis, as a bug (beetle) on

the chin was the symbol for *uta* (corroding ulcer). There exists a written legend among the Incans where undoubtedly is described a disease like syphilis.

Syphilis had a beginning, as every disease has had. This autochthonous disease in America existed from remote times, according to all proofs—Montejo, Ruiz, Seler, Bloch, etc.—so remote that imagination cannot fix its beginning, and at a determined moment it found favourable soil to perpetuate and establish itself, as identical with the great epidemic in Europe of the fifteenth century. The factors developing this genesis were, doubtless, quality of virus, possibly from an animal originally (which I myself believe was the llama, by unnatural intercourse), alcoholism, traumatism, and lack of specific treatment.

The subject of evolution or involution of disease is very interesting. Allow me a few words thereon from my view-point.

It is a fact that when syphilis appears in a virgin soil it establishes itself violently, epidemic and malignant. It soon becomes milder, as in Japan today, by inherited resistance to the germ. Japan has known the disease 1,300 years, while Western Europe has known it only 500 years. Thus the mild germ from a syphilitic Japanese prostitute produces a most vicious type when inoculated in the European. Besides, there is a difference in contagion. Instead of being transmitted by the coition, it becomes oftener transmitted from mouth to mouth, or intermediately. Originally in America, syphilis is thought by prominent medical Americans, to have been more like sarna, a disease of the llamas; transmitted to man as sarna it has taken on a form similar to syphilis.

Tello thinks the epidemic of syphilis of remote time in Peru gradually assumed the form of the famous epidemics called Mal de Sainte Euphémie, Maladie de Chavanne-Leure, Maladie de Brunn, Maladie de Fiume ou de Scherhévo, La Facaldina, Le Sibbens d'Ecosse, La Radezyge, Mal de la baie de Saint Paul, etc.

According to Dr. Barthelemy, alcohol exasperates diseases of the skin. This law applies to all dermatoses. Syphilis (or sarna of llamas) is no exception to this rule.

The principal element of ancient Peruvian feasts was alcohol (corn wine). The cults of Venus and Bacchus went hand-in-hand. In Peru the pack-drivers all had coition with female llamas on their journeys over the mountains, lying down with them to be warmed by their wool. Thus original infection occurred. Later on, in ancient towns of the Andes Mountains the great Sun feasts produced a change in the disease in man. At these the men dressed in skins of llamas, would publicly copulate with a hundred virgins, set apart for the purpose, or without the skins would drink to excess and lead the dancing girls of nine years outside the house, where their will would be satisfied, and, returning to the house, would go on with the festivities. This was the common practice; not a few, but all, did this. The occurrence of diseases of a corroding nature like *uta*, maranas, espundia, mal de los Andes, all influenced the development of the animal disease sarna into syphilis, as we term it. Constant traumatism of the skulls in ancient Yauyos Indians made likely the occurrence of so many syphilitic lesions, found buried in the *chullpas* and *chaukallas* of old Peru.

Virchow has admitted that the greater part of osseous lesions in syphilis came from contusions. Cornil thought that the determining cause of the osseous lesion and of its site consisted in contusions, repeated in the same spot, or frequent traumatism.

It is supposed that ancient Peruvians used mercurial preparations for the cure of sarna of the llamas, and as well for eruptions of syphilis, as they call all the llamas of the Department of Puno "syphilitic llamas."

Salazar de Villazante (Relacion General de las Poblaciones Espanolas del Peru) speaks of the Indians going to Guayaquil for the cure of *bubas* (Spanish name of syphilis) to drink sarsaparilla and water, "which sweats them double that of water alone," and a hospital was built there for the cure of *bubas* among the Indians. Thus it would appear that the disease had somewhat changed from what it had originally been among Indians. Originally it had been cured by sur-

(a) A Reply to the communication of Dr. W. H. S. Jones on "The Virulence of Infectious Diseases."

gery in many cases. See some of the *huacos* potteries of old Peru, where there is undoubted evidence (from pre-Columbian graves, mind you) that syphilis and uta are represented as one and the same disease, and cured by surgical intervention.

As for the conclusion of Dr. Jones that the Spaniards could not have carried out their conquests if this Continent had been fever-stricken as it now is, how about *tabardillo*, which the Spaniards called tabardete (or typhus), "which always came at time of rains," which goes back to the Aymaran and Incan periods? And how about Oroya fever (first stage of verruga)?

Monardes affirms that the Indians employed "*pieдра bezaar*" in "*fiebras pestilenciales y do hay Tavardele*."

Brother Diego de Morales speaks of "the *llaga* of mosquitos" belonging to the coca and rice low-lands at the time of the floods. What was it? And what was the exanthematic epidemic of the reign of Huayna Capac? It was not small-pox, for that only came to Peru in 1533. See "*Ler enfermedad mortae de Huayna Capac*," *Boletin de la Sociedad Geografica de Lecina*, 1896. How about "*caracha*"? How about "*sarampion*"?

Gonzales Suarez ("*Hist. General de la Republica del Ecuador*") believes that "*paludisim*" killed "*Garcilazo*." So does the author of "*Noticias Cronologicas del Cuzco*." As to "*Huayna Capac*," the Inca and his disease, it is said:—"V en este ticapo sobrevino una enfermedad, y pestilencia muy grande en que murieron innumerable de gente de un sarampion que se habrian todos de una lepra incurable, de la cual murio este senor Huayna Capac."

Dr. Patron deduces from the chroniclers that "the disease was eruptive, and by its being contagious and an epidemic, and by the inefficiency of quinine, 'conoce segaramente desde tiempos muy antiguos' en lo que respecta a la enfermedad del Inca, descartar de esta discusion el paludismo (chucchu) de Garcilazo."

The negro of the Conqueror, Panfilo Narvaez, was the one who, in 1518, brought for the first time small-pox to New Spain. It broke out in Quito, Peru, in 1533.

Tifus exanthematico (*tabardillo*) has existed in ancient Peru "from remote times." Typhus did not come with the negroes first to Panama, as the author of "*Negros y Caballos*" says. For typhus pre-Columbino was already there.

Did the Incan die of syphilis imported from Naples or Spain, that "new epidemic" which down to the return of Columbus had presented in Europe "only a sporadic form," as recognised then, or was covered up by the definition, leprosy? Leprosy and syphilis in Europe, then, had been for several centuries hidden under the one name. What produced the change, so that the two diseases were afterwards separated? Fracaster, the great authority, has depicted the disease "syphilis" very different from what we recognise "syphilis" to be to-day.

Altogether the study opened up by these considerations on the origin and unity of diseases is intensely interesting, and reminds one of the objections raised by the Japanese in 1849 against the introduction of vaccination, that it would prevent the parents handing down to the next generation a measure of resistance to the contagion of small-pox. They cited the fact that for 1,300 years free sexual intercourse, while it had spread syphilis through the families, had also in its own time handed down a splendid measure of resistance to the destructive symptoms of the disease.

Syphilisation of the Japanese race has proved really a benefit. Moreover, while the Spaniards really carried out their conquests in the New World, it was not because this Continent was "not fever-stricken," but in spite of it being so stricken. And that "new disease," malaria, which killed Garcilazo, must have been brought here by the Spaniards, if it was not already here, as they surely did bring small-pox and leprosy, and their own kind of syphilis. Yet there were more than enough vicious fevers already here in the coca and rice fields of the Incan Empire to assure them of sufficient obstacles to their success had they not brought a plenty themselves.

Malaria is the same to-day among those Peruvian Indians and their anopheles mosquitoes as it was before

Pizarro. Call it by its earlier name, and there you have it.

## ALCOHOL AND ITS EFFECTS UPON THE CHILD. (a)

By DR. IMRE DOCZI,

Official Reporter to the Alcohol Commission in Budapest.

THE history of the anti-alcohol movement proves that lasting results in the fight against alcoholism can only be achieved when the rising generation is penetrated with a noble conviction thereon, and makes the question a part of its ideals. Youth belongs to the future, and he who knows how to win youth on the side of his ideals rules the future. The most fruitful of the efforts of the countries, therefore, against alcohol will be those who will impress on the youthful minds the evils of alcohol; on the great necessity of fighting against alcohol, as well as the immense advantages arising from the abstinence from strong drink, and in this manner to work up an enthusiasm for total abstinence.

With this object in view, the Minister of Education has had the following questions drawn up for use in various educational establishments:—

1. Is the pupil abstinent?
2. Does the pupil habitually drink intoxicating drinks, and in what quantities?
3. Does he only drink on exceptional occasions, and if so, when and in what quantities?
4. What influence does alcohol exercise on the conduct of the pupil, and his aptitude for doing his school tasks, and on his moral character?
5. Who first gave him alcohol? His parents, a doctor, or who?

Starting from these data, we seek next to impress upon the Hungarian pupil the evil effects of alcohol, and at the same time in doing this we want to be of assistance to the anti-alcohol movement, so that the various professors and teachers in this country must, whether willingly or unwillingly, force the question of alcoholism on the attention of parents and pupils, and let them see it as a deep-rooted social evil, which has already unfortunately commenced enslaving youth. There is no doubt that the Hungarian school children, whose numbers count more than half a million, have in this way attained knowledge of the evil effects of alcohol, and that through their children the parents have been obliged to learn that the question of alcoholism is followed with interest and attention by their children in the schools, so that the evil effects of alcohol shall not extend themselves to children. It must not be taken from this that teachers themselves do not avail themselves of opportunities to bring before the parents the evil effects of alcoholism.

The best and surest means of anti-alcohol propaganda is through schools, and as soon as the schools rally round the flag of anti-alcoholism the cause of total abstinence will gain a complete victory.

Most carefully prepared statistics, based upon the data obtained by the Hungarian Government as to the drinking habits of all the children under the age of eighteen, in all the schools of all classes, both elementary, private, and public, show that 20 per cent. are total abstainers. It is by no means rare to find schools where pupils are given alcohol daily by their parents. Among the poor Slav population this is given in the form of spirits, distilled from grain, or possibly more commonly from potatoes. In many instances the local cir-

(a) Abstract of Paper read before the International Congress on Alcoholism, London, July, 1909.

cumstances are described with great minuteness, and as the best means against the evil it is demanded that the drinking establishments be closed on Sundays.

A sad feature in connection with our propaganda is the fact that many are not clear as to what is meant by "abstinence." Nevertheless, our schools have rendered great service to the cause, and it is to be expected that these efforts will be crowned with good results.

As regards details it is to be noted that a part of the pupils only take alcohol under exceptional circumstances. Such exceptional circumstances are—Sundays and holidays, baptisms, weddings and funerals; amongst workmen and miners on pay days; in the grape-growing districts at vintage time; in agricultural districts at harvest time. On such occasions greater opportunities of indulging in alcohol are given to the people, and to the children also. These opportunities for indulging in intoxicating liquors have in some cases assumed such dimensions that, according to reports received, pupils in the first and second elementary classes come to the schools in quite an intoxicated condition. Reports have also been received of cases of pupils being too intoxicated to be able to do their lessons.

Equally sad is the reading of the report as to the evil effects of alcohol on the pupils; 36 per cent. of the pupils who indulge in alcoholic drinks were found to be careless and idle; 11 per cent. were found dull of comprehension; 13 per cent. were found quite incapable of any capacity for prolonged attention; in 10 per cent. of the cases it was found, especially in the first hours of the morning (8-9), that the pupils gave confused answers; 18 per cent. were very much behind in special subjects requiring extra mental effort, and 10 per cent. showed no evil effects.

The effects on children who indulge in alcohol are still more marked as regards its influence on the mind and character. 30 per cent. of the children were inattentive, nervous, and restless; 15 per cent. melancholy and abnormally shy; 30 per cent. coarse and without any feeling; 9 per cent. vindictive and given to stealing; 18 per cent. immoral; 6 per cent. particularly disinclined to learn; only 20 per cent. showed no signs of any evil effects. As regards the bodily health of the children who indulge in alcohol, three-fifths were found to be of colourless complexion and pale, with sunken cheeks; one-fifth showed arrested development of the body, in only one-fifth was the disturbing influence of alcohol unnoticed.

The statistics also show that in 97 cases out of 100 alcohol was given to the children by the parents, and only in the cases of the remaining three by the doctor. Children were given bread soaked in spirits, in other instances spirits were given to children to stop them from crying. In consequence of the extraordinary cheapness of brandy, in several communities it is given to the children regularly for breakfast. In consequence of the degenerating influence of the effects of alcohol the birthrate amongst such communities is becoming less and less every year. The prejudicial moral effects of the use of alcohol is also further enhanced, that on holidays the children are taken by the parents into the public houses. An hour spent in this atmosphere is enough to completely undermine the character of the child, and to eradicate any feelings of shame.

The result of the collection of these facts shows the sad certainty that alcoholism is unfortunately more widely distributed amongst children than is generally believed to be the case. This, however,

is only a reason that the fight against alcoholism should in every respect be fought with greater energy, and the first step towards this is to enlighten the people upon the total abstinence question and to win them over to the cause.

## OPERATING THEATRES.

### KING'S COLLEGE HOSPITAL.

REMOVAL OF STONES FROM ONE KIDNEY SOME TIME AFTER REMOVAL OF THE OTHER KIDNEY.—MR. PEYTON BEALE operated on a man, æt. 30, whose history was as follows: About 18 months previously Sir Watson Cheyne had removed his left kidney, which was completely disorganised and converted into a mere sac full of calculi. The patient made an uneventful recovery, but within six months began to complain of pains in the right loin, shooting down the right ureter. These continued off and on, and were sometimes associated with absence of urine, so that it was evident that he had periodical attacks of obstruction of the right ureter, and this obstruction was almost certainly due to calculi in view of his past history. Two days before admission he became unable to pass water, having previously passed some urine containing blood, and on admission he was found to be suffering from uræmia. He had a tumour about the size of a cocoanut in the region of his right kidney, and Mr. Beale assumed from his appearance and symptoms on admission, and knowing his past history, that he was suffering from hydronephrosis due to blocking of the upper end of the ureter by calculi, and that in all probability the kidney was almost entirely destroyed, there remaining only a minimum amount of secreting tissue compatible with life. He thought that an operation would give relief, and so he cut down on the right kidney in the lumbar region in the usual manner. On exploring the surface of the organ with the finger, it was found that at one part there was a mass of calculi immediately beneath the kidney capsule. Here the capsule was incised freely, but the calculi could not be removed until they had been broken up. Fortunately, this could be easily done with a pair of forceps, as the calculi were brittle and fairly soft. About 3 oz. of fragments were removed in this way, and on exploring the cavity from which they came by means of the finger, it was quite clear that there was but little cortical kidney substance remaining. The wound was thoroughly irrigated by hot salt solution, and lightly stuffed with wet gauze.

Mr. Beale said that cases like this were, of course, hopeless, but until the final stage it was really very difficult to decide when to operate. Their progress was generally slow, attacks of suppression of urine coming on at intervals, and being accompanied by severe pain, but after each attack the patient was apparently fairly if not quite well. He had on two occasions been called upon to operate upon cases in which one of the kidneys had been previously removed for extensive tuberculous disease and sepsis, but in these cases there was, as a rule, a marked difference, for the patient frequently appeared to be in very good health for five or six years after the removal of the one kidney, and, as a rule, these patients complained of little or nothing until suddenly one day they found themselves unable to pass any urine; they then died from uræmia in the course of a few hours. One of these cases Mr. Beale reported in THE MEDICAL PRESS ("Operating Theatres"), which was complicated by a small calculus impacted in the ureter, but the rapidity of the symptoms may be gathered from the fact that on one morning the patient walked some miles to her work, she was taken suddenly ill at 1 o'clock, and died of uræmia and collapse on the next day.

The present patient was still living seven days after operation, but died on the ninth day from uræmia.

PERINEAL ABSCESS.—The same surgeon operated on a man, æt. about 40, who was admitted with what appeared to be a simple ischio-rectal abscess on the right side. As regards his previous history, the only point of interest was that when he was a child he

had suffered from a perineal abscess which had been opened, it had healed rapidly, and had remained sound. There was a scar in the middle line of the perineum immediately in front of the anus showing where the operation had been performed. The ischio-rectal abscess was opened in the ordinary way, but it was immediately noted that the pus was not like that of an ordinary ischio-rectal abscess, for it was of a light grey colour. On exploring the cavity with the finger, it was found to extend upwards towards the middle line—i.e., into the perineum. On making a counter-opening here, a long probe was found to pass upwards and to the left in front of and some way above the body of the left pubic bone. There was no probe long enough to reach the end of the track, but it was pretty clear that it extended up the sheath of the left psoas muscle. Mr. Beale said that it was not advisable to explore further at that time, but he was pretty sure that there would be a sinus remaining, and later on he proposed to explore higher up and try to reach the origin of the trouble. He had seen pus from an empyæma find its way down the psoas as far as the groin, and he had seen an appendix abscess and a sub-phrenic abscess resulting from a gastric ulcer reach the perineum, but he did not remember ever meeting with a case in which pus passing down the sheath of the left psoas muscle had been found pointing in the right ischio-rectal fossa.

## CORRESPONDENCE.

### FROM OUR SPECIAL CORRESPONDENTS ABROAD.

#### FRANCE.

Paris, August 15th, 1909.

#### TREATMENT OF INSOMNIA.

INSOMNIA can result from very many causes. It is the duty of the practitioner not only to determine the special cause, but also to try simple treatment before prescribing hypnotics, which are sometimes dangerous.

This is particularly the case in acute infectious maladies where any hypnotic preparation paralyzes resistance.

In such cases, baths are more especially indicated. According to the condition of the patients, warm baths or the wet sheet may be utilised. A quiet sleep is thus obtained without injury to the patient.

In diphtheria, although the throat is apparently cured, if the child is agitated, with leaden facies and loss of appetite, grave intoxication may be suspected, and large doses of anti-diphtheritic serum should be injected.

The insomnia of phthisical patients may depend on different factors: cough, painful phenomena, gastric trouble, etc.; all these causes should be treated by appropriate means.

Intoxications enter for a large part into the causes of insomnia: tea or coffee are not supported by many persons, while alcohol provokes a heavy slumber, agitated by numerous nightmares; total suppression is frequently sufficient to bring back normal sleep.

Delirium tremens is often the consequence of alcoholic excesses; insomnia is complete while agitation is well marked and dangerous. Subcutaneous injections of strychnine (1-64 gr. two or three times a day), cold applications to the head, warm baths (95°) for two hours, morning and evening, and the milk diet suffice to bring back sleep. If, however, the insomnia resists this treatment, opium, chloral or bromide of potassium might be given until the desired effect.

Among chronic affections, uræmia is frequently accompanied by sleeplessness. Here milk diet should be prescribed and theobromin.

Where insomnia is produced by pain, analgesics might be given either alone or associated.

Exalgin, 2 gr.  
Phenacetin, 4 gr.  
Antipyrin, 8 gr.

For one wafer; two to be given at an hour's interval.

Pyramidon, 4 gr.  
Phenacetin, 4 gr.  
Hydrobr. of quinine, 2 gr.

For one wafer; two or three a day.

Trional, 10 gr.  
Phenacetin, 4 gr.

For one wafer to be taken at bedtime.

In diseases of the heart, intoxication of renal origin, dilatation of the heart, certain neurasthenic conditions, are the exciting cause. Hydric diet, milk regimen, and small doses of digitalis will generally act well; otherwise valerian, bromides, or small doses of morphia, with absolute rest will be prescribed.

In such patients, however, hypnotics should be used sparingly and with prudence, as cardiac paralysis may result from frequent doses.

In asthmatic attacks, morphia is indicated, and when relief has been obtained, the patient will be given iodide of potassium, alternating with belladonna and arsenic.

For persons suffering from neurasthenic or mental strain, worry, etc., the treatment of insomnia is somewhat delicate. In young men fatigued from intellectual strain at the period of examinations, hypnotics should not be used, they paralyse the cerebral activity. The practitioner should rather prescribe rest, quietness, warm baths and moderate exercise.

A hot bath three hours after the evening meal is frequently useful, or even, as advised by Dr. Huchard, an alternating hot and cold foot bath.

The feet are placed in hot water at 104° for three minutes, and then plunged for half-a-minute into water at a temperature of 68°; this is repeated three times in succession.

The hands might also be plunged into hot water (104°) for half-an-hour.

In persons suffering from moral depression due to money losses, private chagrin, moral fears, hypnotics must be given:

Valerianate of ammonia,  $\frac{1}{2}$  dr.  
Tincture of valerian, 2 dr.  
Peppermint water, 3 oz.

A teaspoonful at bedtime in a little water.

Bromides should not be given indefinitely, while sulphonal, trional, veronal, should be used with precaution, as in large doses they depress the nervous system.

*Simple insomnia*:—A warm bath (95°) before dinner for half-an-hour. Light meals without wine, beer, or coffee. A tablespoonful at bedtime of:

Hydrate of chloral, 2 dr.  
Bromide of potassium, 1 dr.  
Cherry laurel water, 2 dr.  
Syrup of poppy, 2 dr.  
Water, 4 oz.

*Cardiac insomnia*:—A wafer of caffein (5 gr.) at eight in the morning and at four in the afternoon. At bedtime a wafer of:

Pyramidon, 4 gr.  
Valerianate of quinine, 5 gr.  
Bromide of potassium, 8 gr.

*Insomnia of neuropathic patients*:—A warm bath before dinner. At bedtime a large piece of warm cotton wool on the chest and stomach. If hypnotics must be given:

Veronal, 6 gr.  
or  
Hypnal, 15 gr.

*Insomnia of convalescence*:—  
Hydrate of chloral, 2 dr.  
Syrup of poppy, 2 dr.  
Syrup of orange, 1 oz.  
Water, 3 oz.

A tablespoonful at night.

*Insomnia of children*:—Seek the cause (over-feeding, constipation). If it is due only to nervous conditions, bromide of potassium (15 gr.) or:  
Urethane, 10 gr.  
Syrup of orange, 1 oz.  
Water, 1 oz.

Baths at evening and lotions in the morning are very useful.

## GERMANY.

Berlin, August 15th, 1909.

## A NEW REMEDY FOR CATARRHAL AND TUBERCULOUS DISEASES OF THE LUNGS.

WITH the remedies in use so far, for affections of the air passages generally, one is only too forcibly impressed with the scanty results obtained from their employment. This and that new remedy has been vaunted and so highly praised that the physician, however sceptical he may be and distrustful of everything, new or old, is tempted to give it a trial, but with only the faintest hopes of any tangible good effect. With all of them, so far, on giving them a trial it may be truly said that his expectations suffer less disappointment than his hopes, for where you anticipate but little your disappointment will be correspondent. Things being as they are with all known remedies, it need excite little wonder when still fresh and new remedies are brought before our notice. Amongst the latest of these is a tar product, to which the elegant and suggestive name of "Sputan" has been given. Let us hope that in effect it will prove "better than likely," to use a pithy expression of some rural districts.

Sanitätsrat Herr Dr. Dorn (*Deutsche Med. Zeitung*, '09, No. 61), who is Arzt für innere Krankheiten, has had this new remedy in his hands for the last four years, and during this period has submitted it to numerous tests. Sputan, he says, is a slightly alcoholic, aqueous, aromatic, product of tar, which contains in addition to the tar 0.05 per cent. of salicylic acid. He commenced the use of the sputan, he tells us, with all the scepticism the treatment of phthisis is likely to be the parent of, but still hoping that it might do some trifling service in alleviating the condition, and with still slighter hopes that it might—that it might—somewhat retard the devastating progress of the disease, anything further than this, let alone complete cure of the disease, being beyond his power. Stimulated, however, by some striking improvements that some others had obtained by the use of sputan, he gave a renewed attention to the preparation, and placed the cases treated under strict control.

He gives his experiences in 50 cases in which sputan was systematically used, dividing them into three groups, according to the nature, development, and severity of the disease.

The first group comprised the cases of catarrh, in which, however, no morbid change was demonstrable in the lungs. The second took in the suspected cases in which there was a hereditary tendency, the third those who were actually tuberculous, i.e., in which tubercle bacilli were found in the sputum.

With the idea of prophylaxis in mind, he gave the medicine in tablespoonful doses to all cases night and morning. This dose was raised systematically, week by week, so that by the end of four weeks four table-spoonsful were taken at once. This maximum dose was continued until some visible improvement set in, when the quantity was gradually reduced.

In the catarrhal cases, frequently following influenza, the duration of treatment was from three to ten weeks. These cases were of interest, as demonstrating that the new remedy was an enrichment of our anti-catarrhal armamentarium. In the second class of cases the treatment was more intensive, more prolonged, lasting from two to six months. Here out of ten cases nine recovered so far that they were able to take up their work again. The remaining patient was admitted into a sanatorium, and was not heard from further. The observations on the third class of cases, that in which tubercle bacilli were proved to be present in the sputum, in which, therefore, there could be no doubt as to the correctness of the diagnosis, were given more in detail. The cases were twelve in number, a number of whom the writer says were temporarily cured, and were able to resume their occupations. Case XI. was of special interest. It was that of Hilda Z., who was under treatment for three months and a half. The improvement was remarkable; on the last occasion on which the sputum was examined there were scarcely any traces of tubercle bacilli to be found. The in-

crease in weight was a lasting one. From the latest information concerning her, a happy termination to her illness might be justifiably anticipated.

In his opinion, sputan is scarcely ever contra-indicated. Even in the larger doses, it was well borne, with a few exceptions. Frequently an increase of appetite was noticed whilst it was being used. Night sweats were relieved, and increase of weight took place. The improvement of the general condition in a short time was quite noticeable. Here it must be observed, however, that most of the cases treated were of the poorer classes, so that the improved diet they received, and generally improved surroundings were, perhaps, accountable for some of the general improvement. The writer does not claim that his observations justify a definite conclusion, but they lend encouragement to further trials of the drug. He would enter a protest against the practice of limiting the treatment of tuberculous cases in sanatoria to hygienic and dietetic means, and would combine this with the best medicinal treatment available.

## AUSTRIA.

Vienna, August 15th, 1909.

## TRICHOCEPHALUS DISPAR.

At the Gesellschaft für Innere Medizin, Gaustalla presented a male patient, æt. 40, who suffered from "flagellate enteritis" from the trichocephalus dispar. Trichocephalus abounds in the caput cæcum, and was first noticed by Morgagni about 1760 or 1761. The story goes that a student of Göttingen was dissecting a girl, æt. 5, when he accidentally opened the caput cæcum and a few of these worms crawled out. Wrisberg and other students considered them new entozoa, while the demonstrator of anatomy at the time assured them that they were ascaris, or another form of oxyuris. A dispute arose, and the parasite got a new name for the time being as trichinalis or hair tail. About this time an epidemic raged in the French army stationed at Göttingen, and the disease was described as morbus mucosus, and this entozoon was frequently found in the bodies of the soldiers that died.

Later investigation, however, proved that this new name, trichinalis, or hair tail, was not appropriate, as the long hair formation was the head, and not the tail; hence trichocephalus dispar had to be adopted, the Germans calling it "peitch wurm," or whip worm.

Now, from this whip worm we get the disease flagellate enteritis. The worm does not seem to be common in England, although Cobbold accused the pathologist in his time for negligence in not discovering it, but the vigilance of the pathologist since that time has not yet added to our knowledge of the disease. Gaustalla tells us his patient had suffered for the last 40 years from sudden attacks of diarrhoea, with fever and severe pain in the abdomen. On admission for this diarrhoea he had well-marked petechiæ on the extremities, dyspnoea, enlargement of the spleen and liver, with pain over abdomen and many of the bones on the slightest pressure. The number of red blood corpuscles were 2,800,000; hæmoglobin, according to Fleische, 20; increased mononuclear leucocytes, and 9 per cent. of eosinophile cells. The hydrochloric acid in the stomach was greatly reduced, the stools fluid and containing the entozoon trichocephalus and alkaline in reaction. A large number of flagellatæ resembling circa monads, with the peculiar ova of the trichocephalus dispar, proved the cause of the disorder.

## ACUTE ENCEPHALITIS.

Strumpell presented a female with an obscure form of encephalitis. She had a somewhat unsteady gait and a very sensitive patellar reflex, as well as active abdominal reflex, well-marked nystagmus, but no disturbance in the sensory nerves.

About two months ago, according to her history, she suddenly took headache, with vomiting, vertigo, ataxia, nystagmus, and bulbar disturbance in speech, with abducent paresis in both eyes. From these symptoms Strumpell thought the encephalitis was confined to the region of the pons, whatever the origin might be.

He also presented a severe case of multiple sclerosis and a man with hysteria. The latter had a peculiar saltatory reflex cramp, which had set in suddenly after a fall. His left side was anæsthetic, and he had imperfect smell and taste.

Schlesinger said he had also seen the patient some time ago, and had seen the cramp disappear quite suddenly. The spasm was more like a sailor's dance, and, as the patient belonged to that profession, he thought more like an uncontrollable imitation of the Matroser dance.

#### CURE FOR MORPHIA MANIA.

Schlesinger read a few notes on his experiment with "skopolamin-dionin" in cases of confirmed morphia mania. His mode of treatment was to prepare a mixture of morphia, 0.2 gramme; skopolamin, 0.00025 gramme; dionin, 0.3 gramme; and water, 10 grammes. This was injected twice to four times a day at the beginning. The next day the injections were the same, but the amount of morphia was diminished. The morphia is gradually reduced every succeeding day till the eighth or fourteenth, when it is withdrawn altogether. After this the reduction of the skopolamin-dionin commences till the whole is withdrawn. The danger connected with this treatment is almost *nil*, and is usually effective in curing the habit. An important feature in treatment is the freshness of the preparation, as anything three days' old should not be used.

Noorden agreed with Schlesinger in the treatment, but was doubtful about the permanency of the cure, as he found patients were easily led back into the old habit.

#### HÆMOLYSIS OF IRON AND ARSENIC.

Strasser and Neumann supplemented their former experiment with iron and arsenic in different diseases. The hæmolysis is conducted in what they call a hypotonic solution of salt, whose concentration is measured, and the time for the solution is fixed at 15 minutes. The following concentrations or isotonic index in the different diseases were required:—Normal blood required 0.39 per cent.; polycythæmia rubra, 0.38 per cent.; icterus, 0.33 per cent.; leukæmia, 0.44 per cent.; chlorosis, 0.29 per cent.; secondary anæmia, 0.34 per cent. to 0.38 per cent.; anæmia, 0.39 per cent.; tuberculosis with anæmia, 0.39 per cent. In chlorosis, when iron was given, the isotonic index was 0.28 per cent., while the hæmoglobin was 28 per cent. On the other hand, it was 0.39 per cent. when the hæmoglobin was 70 per cent. In arterio-sclerosis, with injections of natrium kakodylicum, the index was 0.41 per cent., but after several months' treatment it fell to 0.31 per cent. In myelogenic leukæmia it fell from 0.44 to 0.38 per cent. These isotonic indices constantly sink when the hæmoglobin index rises.

#### HUNGARY.

Budapest, August 15th, 1909.

#### THE MOLECULAR AND CHEMICAL RELATIONSHIP OF TRANSUDATES AND EXUDATES.

At the recent meeting of the Kolozsvár Medical Society, Dr. Purjesz read a paper on the above subject. He conducted extensive researches in this field, with the following results: The molecular concentration phenomena of transudates and exudates are substantially the same. The osmotic concentration and the concentration of electrolytes in both exudates and transudates are approximately the same as those of normal blood serum. Just as in the latter, so in the former, the concentration of the electrolytes presents slighter variations than the total concentration. It seems that the human serosa in both exudative and transudative processes always allow the inorganic salts to pass through in the same concentration, while the organic substances, according to the nature of the disease, are more or less held back. The content in ash is no reliable index of the content in electrolytes. From the standpoint of the No-ions, transudates and exudates are neutral, like blood serum, although, like the latter, they both contain tritratable alkali. The lecturer has not been able to discover any relation between the content in albumin and dry substance, on the one hand, and specific gravity on the other. There

are no particular differences between the two groups of fluids as regards total proteids, serum-albumin, serum globulins, ash and chlorides.

#### THE ACTION OF IODIDES IN ARTERIO-SCLEROSIS.

Dr. Veress said that, although the use of this drug in the treatment of this condition is very extensive, yet but little is known of its mode of action. He presented the results of a series of observations in young men, otherwise healthy, to whom potassium iodide was administered in daily doses of from 0.3 to 0.5 gr., for periods of ten to fourteen days. It has been claimed that this drug has no vaso-dilating action. Examination of the blood from the experimental subjects showed that there was a marked loss of viscosity, sometimes as much as 10 per cent. This apparently explains most of the therapeutic effects of the drug, as its action in increasing the fluid character of the blood is equivalent to dilatation of the vessels, for the reason that the stream flows more rapidly. This also shows that the drug must be continued for long periods in order to produce any effects. The serum does not become fluid to the same degree as the blood *en masse*, and sometimes is even increased in density, so that the change appears to be governed by the behaviour of the cellular elements of the blood alone.

#### RARER FORMS OF RHEUMATISM.

Dr. Kanitz made some interesting comments on this subject. He believes that a sharp line must be drawn between muscular and joint rheumatism. To secure uniformity and to avoid confusion, the term muscular rheumatism ought to be dropped, and the word rheumatism applied to that inflammatory condition of the various locomotive organs and their appendages which results from sudden changes of temperature. Persons inclined to rheumatism need not therefore fear intense, uniform cold, but rather overheating, specially that brought about by muscular exertion, followed by sudden rest and cooling. The quickest and most reliable remedy in cases of fresh or acute rheumatism is exercise. The patient may safely indulge in all those movements which cause pain, but care should be taken to exclude joint rheumatism. Chronic rheumatism can only be cured by mechanotherapy, in which active and passive movements play an important part. Among the rarer sites for rheumatism which are little mentioned in the literature are the following. A rheumatic process in the periosteum of the ribs, the sternum, and the long bones, rheumatism of the diaphragm, isolated rheumatism of the coccyx and the pelvic outlet, and localised rheumatism of the muscles of mastication. Instances of these are described where good results were secured in all but that of the diaphragm by forcible massage. For rheumatism of the diaphragm the Faradic current gave some relief.

## LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

#### THE DECLINING BIRTH-RATE.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—Like your correspondent, "A Student of Sociology," I have from time to time trespassed on your valuable space with regard to this momentous problem, but have no intention on the present occasion of repeating myself in replying to his letter in your last issue.

It is scarcely necessary to remind him that there exists no striking analogy between a country like France with a declining birth-rate and *diminishing* population, and England with a declining birth-rate and an *increasing* population—I believe an increase of about 500,000 yearly. What to do with this surplus we are at our own wits' end to know. At any rate, I cannot recall any prominent politician, of whatever shade of political thought, who has had the boldness to ask for more.

Your correspondent, knowing as he must these facts, reduces the problem to very simple proportions by suggesting that we should deport our superfluity over-

seas, so as to populate our Colonies and feed our Empire with English blood. Now, Sir, viewing his suggestion under the most favourable circumstances, and even assuming, for argument's sake, that our surplus population comprises for the most part the sturdy and those best adapted for agricultural pursuits, how does the question stand? Our Colonies require us to assist in the cultivation of their land, but this by the very class of emigrant it is to our interest to keep at home to till our own soil, in order to enable us to maintain a much larger population than possible under present conditions. Assuming, however, that your correspondent's suggestions are practical, the fatal and inevitable result of his system would be, that the export of our best blood and the retention in our own country of the inferior (our Colonies selecting the healthy only), including the importation of the wretched class of aliens who of late years have favoured us with their patronage, must necessarily spell national decadence.

As a last word, let me ask your correspondent whether he feels such security in the future (*tempus omnia revelat*), that when our Colonies, with their vast expanses of land, become cultivated, with their corresponding numerous populations, and possess, as no doubt they will, armies and navies of their own, we shall still hold all or any of these colonial possessions as an integral part of the British Empire to which we can send our surplus population? In our efforts to ameliorate present conditions, we must not overlook future possibilities. We should, I think, strive earnestly to retain our best blood by making practical the oft-repeated dictum, "back to the land," for the fuller and more profitable cultivation of its resources, rather than offer encouragement to the thriftless propagation of the weakling.

I am, Sir, yours truly,

CLEMENT H. SERS, M.R.C.S.

Brighton, August 12th, 1909.

#### THE NORMYL TREATMENT.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—This is the last letter with which I shall, for the present, trouble you on this subject. The space you have kindly afforded for the correspondence has, I think, not been wasted. The letters have once more brought to the front the fact that educated and cultivated men, holding distinguished positions in learned professions other than scientific, are very commonly devoid of knowledge of scientific methods, unaware of the meaning of scientific fact, and unappreciative of the character of scientific demonstration. In no direction is application of the most rigorous scientific methods more necessary than in therapeutics, in no direction is scientific scepticism so strongly called for as in regard to the claims of quack remedies. To the unscientific mind, the *post hoc, propter hoc* line of reasoning suffices; whilst the ignorant and credulous public are mostly inclined to accept a blatant statement because it is impossible. Prove to them that Dr. Bogus's pills contain nothing but jalap, and Dr. Swindle's ointment nothing but coloured fat, and they will still urge that they don't care for scientific reasoning, having known cases in which these remedies had cured the worst cases of kidney disease, and the most hopeless cases of cancer, as remedies for which they were advertised. They are like the people described by George Eliot, who will reluctantly admit that, as a rule, two sides of a triangle are together greater than the third side, but will qualify this admission by the statement that, after all, we must be careful, as it is so easy to carry mathematical reasoning too far. That portion of the people whose intellectual calibre is too narrow to enable them to grasp the rudimentary principles of science can only be helped by their leaders; that such leaders are so few in these islands is due to the fact that a great part of our higher classes have a lofty scorn of science; they are not taught to respect it at school, and it is generally ignored in every scheme of education in which a practical knowledge of it is not essential.

I am, Sir, yours truly,

MEDICAL TEMPERANCE REFORMER.

August 13th, 1909.

## OBITUARY.

THEODORE DAVIS, M.D.LOND., F.R.C.S.

By the death of Dr. Theodore Davis, F.R.C.S., the town of Clevedon, Somerset, loses its oldest doctor. Born in 1834, Dr. Davis studied for a time at Queen's College, Birmingham, and afterwards proceeded to London, where he entered St. Bartholomew's Hospital as a student. He passed the required examination for the Fellowship of the Royal College of Surgeons in 1859, and two years later obtained the M.D. degree of London University. Dr. Davis succeeded to his father's practice at Clevedon, and father and son completed eighty years' continuous medical practice in the town.

## SPECIAL ARTICLES.

### THE HEALTH OF DUBLIN.

THE Report on the Public Health of Dublin for the year 1908, by the Medical Officer of Health, Sir Charles Cameron, is a bulky volume of nearly 200 pages, handsomely printed. A great deal of space is taken up with somewhat extraneous matter—extracts from the Registrar-General's Returns, meteorological statistics reported by Sir John Moore, and desultory remarks of one sort or another. A list of the officials and employees of the Public Health Department, from the Lord Mayor to the van drivers, is not impressive, when we notice that the Medical Officer of Health, who is not a whole time official, is left without the help of any medical assistant, or of anyone skilled in public health work, or, as far as we can judge, in bacteriology. It is true that the city dispensary medical officers are supposed to supervise the public health of their respective districts, but it can hardly be supposed that serious duties are expected in return for the nominal salaries given. That some of them do work far in excess of what is expected of them is no defence of the present impossible system.

The birth-rate in Dublin is remarkably high—32 per 1,000 of the estimated population, and shows an increase of 0.7 on the previous year. In London, Glasgow, and other British cities, on the other hand, the birth-rate shows a steady decrease. The excess of births over deaths was 2,739—not, as the Report states, 2,739 "per 1,000 persons living." The deaths in the Dublin registration area were 9,070 in number, of which no less than 3,884, or 42.8 per cent., occurred in workhouses, hospitals, lunatic asylums, and prisons. In the large English towns only about 18 per cent. of the deaths take place in such institutions. The corrected death-rate for Dublin for the year was 23.4 per 1,000 persons living.

Of 7,094 deaths which occurred in the city, 576 were caused by zymotic diseases. The most lethal of these diseases were measles, with 130 deaths; diarrhoeal diseases, with 275; whooping-cough, with 75; and typhoid, with 47. The deaths from diarrhoeal diseases fluctuate from year to year, a hot summer apparently leading to a high mortality. The number of deaths from typhoid shows a considerable increase on the numbers of the immediately precedent years—40, 42, 32, in 1905, 1906, 1907 respectively. This is the more to be regretted as typhoid had declined so much in the past ten years we had begun to hope it might soon disappear. In 1893—a year of great drought, when the Dublin water supply ran short and the citizens were put to straits to get water—the number of deaths from typhoid fever was 218. The following year it was 104, rising in 1898 to 135. From 1899 down to 1907 there was a fairly steady fall, but the number for 1908 is the highest since 1904; 956 deaths from phthisis were registered in 1908. Sir Charles Cameron relates the formation of a Joint Hospital Board representing various bodies in the County Dublin, and the purchase of a site for a sanatorium. What is being done in this matter?

The death-rate for Dublin was 23.4 per 1,000 living, the mean rate for the 20 largest Irish towns being 20.2, and for the 76 largest English towns 14.9. Sir Charles

Cameron appears to suggest that this appalling difference is due to greater poverty in Irish towns. It may be true that poverty is more widespread in Ireland than in England, but it certainly is not true that it is so extreme anywhere in Ireland as in London and certain other of the great English cities. The real difference is, that in England there is some attempt at efficiency of sanitary administration, while in Ireland sanitary administration would be a farce but that it is so fatal in its results. As far as we can learn, in the whole of Ireland there is only one Medical Officer of Health who is paid to give his whole time to his sanitary duties. When one compares the Dublin death-rate with that of some English towns of about the size of Dublin, the comparison is startling. Of approximately equal population to Dublin are West Ham, Nottingham, Bradford, Hull, and Newcastle-on-Tyne. The death-rate in these towns is 13.9, 15.2, 15.5, 16.2, and 16 respectively. In Dublin it is, as we said, 23.4. Again, comparing the mortality in Dublin with that of approximately equal proportions in the London boroughs, we find that Islington, Stepney, Lambeth, Wandsworth, and Camberwell have respectively death-rates of 13.9, 17.1, 12.5, 11.5, and 12.4. Moreover, not a single one of the 76 largest English towns, nor of the London metropolitan boroughs, has a mortality rate above 20 per 1,000.

On looking at the subject of infant mortality, we find that here, too, Dublin has a pre-eminence. In London the infant mortality under one year is 113 among every 1,000 births. In the 75 next largest English towns it is 134. In Dublin it is 146. Moreover, we may add that in Dublin there are comparatively few married women employed in industrial work.

Sir Charles Cameron gives some general notes on tenement dwellings which illustrate the extreme poverty of many of the inhabitants. Forty-four houses were closed during the year as unfit for human habitation.

In the section of the Report dealing with the public baths, we meet with an alarming reference to "three men employed in the baths having died from consumption within a period of 12 months." In view of this, we cannot wonder that the Constabulary authorities ceased for a time to send their men to the baths, giving as a reason the prevalence of sickness amongst "the young policemen attending the swimming lessons."

The expenditure of the Public Health Department for the year ending March 31st, 1908, was £18,190 10s. 11d.

## SPECIAL REPORTS.

### THE SEVENTY-SEVENTH ANNUAL MEETING OF THE BRITISH MEDICAL ASSOCIATION AT BELFAST.

[FROM OUR SPECIAL CORRESPONDENT.]

#### EXHIBITION OF DRUGS, FOODS, INSTRUMENTS, ETC.—(CONCLUDING NOTICE.)

THE exhibits this year were in excess of the usual number, but it cannot be said that there were many novelties, so that our report, brief as we have tried to make it, becomes little else than a repetition of previous essays.

The Miol Manufacturing Co. showed samples of their new preparation, and gave full particulars of the way in which iodine is naturally combined with it, so that no depression is caused by its administration. This nutriment has met with considerable favour by the profession in Ireland, having been found most useful in the early stages of phthisis.

Messrs. Nestlé and Co.'s Swiss Milk and Milo Food are well known, and not less so is Peter's Milk Chocolate, shown by the same firm. We think it somewhat unfortunate that the foregoing preparation (Miol) and Messrs. Nestlé's excellent food for infants (Milo) should have names given them so much alike, the same letters with merely a transposition; this we fear is likely to lead to mistakes and unnecessary confusion.

Messrs. George Mitchell, Ltd., of Dublin and Belfast, showed samples of their smoking mixtures, cigars and cigarettes, already well and favourably known among Irish medical men.

Messrs. J. Morgan, Richards and Sons showed lactopeptine in its various forms, to which fresh additions are constantly being made.

The Saccharin Corporation, Ltd., have in "Novocain" a keen competitor with cocaine for popular favour, and its merits and uses were explained at their stand, which attracted universal attention.

The Angier Chemical Co. showed their popular emulsion of petroleum, and their recently introduced throat tablets of purified petroleum, combined with pure elm bark.

Messrs. Zimmer and Co. showed a number of modern synthetic preparations, some already well known, and others recently introduced, such as validol, euquinine, urosine, and allosan.

Messrs. Ingram and Royle, Ltd., had a wonderful exhibit of natural mineral waters, including about fifty different varieties, some familiar and some which were certainly new to most visitors.

Friedrichshall Water had a stand of its own, showing an array of testimonials which certainly entitled it to its pre-eminence.

The Anglo-American Pharmaceutical Co. showed Huxley's preparations, foremost of which were the various glycerophosphates, combined with pepsin, red bone marrow, hæmoglobin, etc. The Pasteur Vaccine Co.'s biological products were also shown, including their new "Fermentactyl." This firm were in a peculiarly unfortunate position, as only a day or so before the exhibition opened, their extensive laboratories at Croydon were burned to the ground, rendering it almost impossible to keep their stand fully supplied for this meeting.

Messrs. H. and F. Kirby showed Purgen, their "ideal purgative," in its different strengths, and their "Ideal Valve" feeder, in which the valve is of solid glass, and cannot leak or fall out.

Liebig's Extract of Meat Co. showed their familiar Lemco and Oxo and several newer preparations for household use, such as Fray Bentos ox tongues, corned beef, etc., and "Bifti," a penny pure beef tablet for making gravy or soup.

At Stand No. 76, A. Wander, Ph.D., exhibited some preparations, which appeared to be novelties to many present, if one might judge of the interest that seemed to be centred in the display. It is claimed for "Ovaltine" that it is a complete food, containing every dietetic element required by the human organism, prepared in the form of a granular powder. This manufacturer also showed his new preparation of dry extract of malt, and of "Formitrol," a safe and pleasant form for the administration of formaldehyde in chronic and acute pharyngitis.

A new exhibitor at these annual meetings occupied Stand No. 18 with an imposing display of special medicinal waters. Messrs. Findlater and Co. are now the special agents for many Continental waters hitherto little known in this country, but which are now being brought to the front. Carabana, an aperient of considerable strength; Wildungen, the favourite water in Germany for kidney and bladder troubles, and Royal Ems, a favourite in catarrhal affections of the mucous membranes, etc.

## MEDICAL NEWS IN BRIEF.

### The Forthcoming International Medical Congress.

THE preliminaries of the Sixteenth International Medical Congress to be held at Buda Pesth on August 29th are practically arranged, and the executive committee is engaged in preparing a detailed programme of the various functions and fêtes. Particular care has been taken with regard to the accommodation of the congressionists, and a great number of hotel rooms and others have been reserved by the Central Travelling Ticket Office (V. Vigadó-ter, 1 Buda Pesth) on behalf of those who have not yet sent in their

adhesions and subscriptions. At the same time it will be well for all intending visitors to write in advance in order to profit by the railway and steamboat companies' reduced fares and other advantages offered to members of the assembly. Any further information may be obtained (up to August 19th) from the Secretary-General of the Congress: VIII. Eszterházy-utca, 7, Buda Pesth; and after that date: VIII. Muzeum-körút, 6/8, Buda Pesth.

#### The Success of Sanatorium Treatment.

At the annual meeting of the governors of the West Wales Sanatorium, held at Carmarthen a few days since, the Medical Superintendent (Dr. Adams) submitted his report for the past six months, in the course of which he said with regard to the 30 patients who had been discharged during the period, the results were more than satisfactory. They were infinitely better than he in his most sanguine mood ever anticipated. Half of them were back at the work they were doing before they broke down in health; eight, acting on his advice, had changed their occupation, whilst three who were quite fit for work but were not obliged to do so. One died of a complication after leaving the Sanatorium, and the other three were discharged as unsuitable cases, and were now practising the treatment they learnt at the institution at home. The letters he had received from the discharged patients were most gratifying. He was glad to report that not nearly so many hopeless cases were being recommended for treatment. It seemed as if medical men were realising the importance of only sending early cases.

#### Guardians and Medical Officers.

A PROPOSAL of the Chorlton Board of Guardians that representations should be made to the Local Government Board in favour of allowing all medical men to act as district medical officers and public vaccinators, and to be paid at a scale to be fixed by the Guardians, was brought before the meeting of the Finance and General Purposes Committee of the Salford Guardians.

On Friday last Mr. Dobson said that such a system was in operation in Scotland, and suggested that further information should be obtained.

Mr. Bescoby, who said that the resolution of the Chorlton Union was brought forward by the Socialist section, moved that no action should be taken. Such a system, he thought, would open the door to a good deal of corruption.

The motion to take no action was adopted.

The question of payment to the Poor-law Relieving Officers for the additional work entailed by the inquiries under the Old Age Pension Act was deferred.

#### Hospital Treatment Experiment at Coventry.

A SCHEME of continued hospital treatment, which appears to have much to commend it, is being tried as an experiment at Coventry. The hospital authorities are sending their convalescent patients to farmhouses to recuperate, and so far the results have been eminently satisfactory. In most small towns no recognised system exists for dealing with patients after they are able to dispense with the regular attention of a medical man; and Birmingham itself was not much better off until the establishment and development of the work of the Hospital Saturday Fund. The obvious advantage of the Coventry plan is that the individual effort of the poor is assisted, and that the convalescent patient is kept under medical supervision, and adequately and properly provided for in the way of food. It is not within the power of many towns to possess, as their own property, homes of rest at the seaside, so that the country farm-house hiring system would appear to be the next best thing, as it achieves beneficent results without incurring a big financial responsibility.

#### Drunk or Dying.

An inquest was held at Camberwell, on August 13th, respecting the death of Annie Labrun, wife of an engineer living in Warner Road. Late on the night of Bank Holiday, it was stated, Labrun and his wife

were returning home, when the woman fell in a faint. As the husband was assisting his wife into a cab, two constables arrived, and, accusing him of being drunk, took him to the station. Labrun, in his evidence, stated that he was ill-treated. When his wife was brought in on an ambulance he protested that she was ill. He was thereupon seized and placed in a cell for the night. Next day he was fined at the police court. Police-Constable Baker described the arrest of Labrun, and said the deceased was drunk. The Coroner: How did you find that out? Witness: She smelt strongly. The Coroner: That is no proof. Witness sent for the ambulance, and took deceased to the station, where she was charged. The Coroner: Was a doctor sent for?—Witness: No. Why?—She did not ask for one. Police-Sergeant Curtis said that he visited deceased several times during the night. At twenty minutes past seven o'clock he thought she was not making so much progress as "drunks" ought to, and he sent for the divisional surgeon. At ten o'clock she was worse, and the doctor ordered her to the infirmary. Dr. J. C. Keats, Medical Officer at Camberwell Infirmary, said that he received deceased and found her in a dying state. She died last Tuesday as the result of a fractured skull. The Coroner: I can see how it happened. Deceased fell, a police constable comes up and says she is drunk, the husband denies it, gets excited, etc.

The jury returned a verdict of "Accidental Death," and added that there was no proof that deceased was intoxicated at the time. They were also of opinion that a doctor should be called in in all cases of this kind.

#### Spring Water and Typhoid Fever.

THE Oldham Medical Officer of Health (Dr. Wilkinson) has issued a warning to the Health Committee on the danger of holiday-makers drinking water from country springs. He said it was a common thing for people when they found what looked like a clear spring to take a drink. During the past week two cases of typhoid fever had been reported, which were probably due to drinking water from a spring in the Saddleworth district.

#### Questions in Parliament.

Sir William Collins asked the Home Secretary whether he was aware of the extensive use of tetra-chloride of carbon as a hair-wash; whether his attention had been called to a recent death of a young lady while her hair was being shampooed with this compound; whether his attention had been directed to the poisonous properties of carbon tetra-chloride; whether any restrictions upon the sale or use of this compound at present exist; and whether he proposed to take any steps in the matter.

Mr. Gladstone replied:—My attention has been called to the use of tetra-chloride of carbon as a hair-wash, to the very great danger involved, and to the death referred to by my honourable friend. I am informed by the Privy Council that tetra-chloride of carbon is not a poison within the meaning of the Pharmacy Acts, and there are, therefore, no restrictions as to its sale. As regards the steps to be taken in the matter, I can only say that the Director of Public Prosecutions has the question of a prosecution now under his consideration.

#### Death After Chloroform.

At Holborn, on August 13th, Mr. Schroder held an inquest on the body of Eric Sidney Rolfe, the 18 months' old son of a stationer's assistant living at Bushey.

The child was admitted to the Hospital for Sick Children, Great Ormond Street, on Monday, to undergo an operation, which was performed on the following day, the patient being anaesthetised with chloroform. The child recovered quite normally, said Dr. Mills, the House Surgeon, and went on well until Wednesday afternoon, when symptoms strongly suggesting the after effects of chloroform developed. Death took place on Wednesday night, and the post-mortem examination showed that it was due to heart failure resulting from delayed chloroform poisoning.

Nothing further could have been done to guard against it.

The jury returned a verdict of "Death from misadventure."

The Coroner observed that these cases of chloroform poisoning were very rare, about one in two years coming under his notice out of many thousands of operations.

#### Mortality from Measles.

At a meeting of Darlaston Urban Council, on August 10th, the Medical Officer of Health (Dr. S. Partridge) reported the high death-rate of 27 per 1,000, and stated that out of 33 deaths 20 were due to measles and one to scarlet fever. The latter disease had now practically subsided, but there had been a considerable increase in measles, the chief obstacles in combating which were the difficulty of distinguishing the initial stages from an ordinary cold, the impossibility of obtaining adequate isolation in a working-class population, and the indifference of parents. The summer school vacation would, it was hoped, assist in stamping out the disease.

#### Tuberculosis in Paris.

In an official report addressed to the Préfet of the Seine, M. Juillerat, Head of the Administrative Bureau of the Sanitary Service of the City of Paris, notes that the number of deaths from pulmonary tuberculosis which occurred in Paris last year was 10,263. These figures are the same as for 1907. As the population has slightly increased, it may be concluded that consumption has decreased somewhat.

M. Juillerat states further that during the two and a half years he has been studying the question whether cancer is contagious or not he has noticed that it has a marked tendency to return to houses already visited by it.

#### The King's "Cure."

THE King, with the members of his suite, arrived at Marienbad on August 11th. The season is now at its height, and the town is crowded with visitors of all nationalities, including many British and Americans. This is the King's ninth visit to Marienbad.

In view of the heat, the King left the train at Eger and motored to Marienbad. In the large hall of the Hotel Weimar, to welcome His Majesty, were assembled Sir Fairfax Cartwright, British Ambassador in Vienna; the Hon. T. Russell, Bezirkshauptmann Prince Liechtenstein, Praelat Helmer Abbot of Tepl, Burgomaster Dr. Heinrich Reiniger, Captain Frankl, of the Austrian Navy; and other municipal authorities. Dr. Ott certifies the King to be in excellent health.

#### Gresham College.

THE City Corporation of London have decided to close Gresham College. The site will be advertised for sale, and the proceeds devoted to the establishment of scholarships and the delivery of lectures. The Gresham Trust was founded by Sir Thomas Gresham, the creator of the first Royal Exchange, which was opened in 1568. A scheme has lately been under discussion for the remodelling of Gresham College, but this has been abandoned. The site of the college is valued at over £50,000.

#### University of London.

THE following candidates have passed the First Examination for Medical Degrees (alphabetically arranged):—

D. R. Alexander, Elizabeth L. Ashby, F. M. Barnes, Irene Bastow, W. R. Blore, J. Bostock, G. K. Bowes, Alice D. Brooks, F. C. S. Broome, O. D. Brownfield, Isabel F. Buckle, W. Burt, F. W. Chamberlain, H. G. Chaplin, J. E. Cheesman, H. A. De Morgan, A. R. C. Doorly, C. H. Edwards, A. F. El-Hakim, R. Ellis, P. O. Ellison, H. J. O. Ewing, C. H. Gould, D. W. Griffith, Mary E. Harding, J. R. Harris, C. C. Harrison, H. W. Hay, H. L. Hitchings, A. G. Holman, H. J. Hoyte, C. E. Jenkins, K. W. Lewis, O. C. Link, I. H. Lloyd-Williams, R. J. McN. Love, N. P. L. Lumb, W. F. MacAlevey, J. N. Mehta, J. Y. Moore, A. D. Morris, P. T. Patel, T. B. Paul, I. H. Pearse, J. L. Priston, C. E. Procter, F. T. Rees, R. E. Roberts, J. A. Robinson, W. E. R.

Saunders, H. R. Sheppard, R. H. Simpson, J. S. Sloper, E. S. Sowerby, C. W. Sparks, J. E. Stacey, G. Stapleton, J. Stephenson, W. E. Taylor, N. Tribe, H. P. Whitworth, G. R. C. Wilson, A. G. Winter, H. G. Winter.

The following students, who took a portion of the Examination under old regulations, have now completed it:—

W. C. P. Barrett, T. D. C. Barry, F. V. Bevan-Brown, Ursula P. Blackwell, P. Butler, Y.-J. Cieh, A. S. Cohen, Dora C. Colebrook, M. B. Cooper, S. A. Cornelius, J. K. Davies, C. F. Hacker, S. S. B. Harrison, L. Kingdon, R. W. Little, D. M. MacManus, G. Matthews, A. N. Minns, J. E. Pearce, S. H. Robinson, G. W. R. Rudkin, E. A. Scott, G. D. Shann, M. U. Wilson, S. Y. Wong.

The following have passed the Second Examination for Medical Degrees, Part I:—

B. W. Armstrong, J. R. Barrow-Clough, R. M. Beath, K. Biggs, P. Butler, G. M. Campbell, A. H. Christie, J. A. Cowan, M. J. Cronin, F. E. Daunt, H. W. Davies, H. F. Davies, J. Y. Dent, G. D. Eccles, H. T. Evans, W. S. Evans, F. R. Fletcher, W. B. Foley, K. M. L. Gamgee, G. A. Gassmann, F. A. M. J. Goldie, U. Griffin, R. L. Horton, R. O. H. Jones, M. A. Jukes, R. M. Kharegat, W. J. T. Kimber, E. P. Langley, E. A. C. Langton, C. Leatham, W. Leslie, E. D. Lindow, M. A. Lloyd, H. R. Lowenfeld, A. G. Maitland-Jones, R. Mallet, L. A. Martin, G. S. Miller, W. E. Milligan, D. E. Morley, Edith M. N. Moss, C. E. Petley, J. A. Poole, Edna M. Powell, R. A. Preston, J. B. Randall, Winifred M. Ray, L. N. Reece, F. C. Robbs, C. S. L. Roberts, G. H. Roberts, H. C. Rook, J. A. Ryle, E. D. Scott, C. Sherris, A. J. E. Smith, H. E. Smith, M. E. E. Smith, S. Smith, W. H. D. Smith, W. C. Spackman, C. K. Sylvester, H. Taylor, J. R. K. Thomson, T. B. Vaile, Mary A. Van Ingen, H. C. Viehoff, E. W. Wade, A. S. Wakely, J. R. M. Whigham, J. D. Wilkinson, J. D. Wilkinson, A. Wills, A. Wilson, O. R. L. Wilson, A. W. Woo.

#### Royal College of Physicians of London.

THE following candidates, having passed the required examinations, have been admitted members of the College:—Edwin Greaves Fearnside, M.A., M.B. Cantab, London Hospital; William Errington Hume, M.B. Cantab, London Hospital, and Berlin; James Lindsay, M.D., Edinburgh University; Henry MacCormac, M.B., Edinburgh University; Walter Malden, M.A., M.D. Cantab, M.R.C.S., St. Bartholomew's Hospital; Arthur Hallows Miller, M.A., M.B. Cantab., Guy's Hospital; Patrick Thomas O'Sullivan, M.D., Royal University of Ireland, Queen's College, Cork; Leonard Gregory Parsons, M.D. Lond., L.R.C.P., M.R.C.S., Birmingham University.

#### Royal Army Medical Corps.

THE following is a list of successful candidates, arranged in the order of merit, for Commissions in the Royal Army Medical Corps at the recent examination in London, when 54 candidates entered:—

G. H. Dive, St. Bart's Hosp., M.R.C.S., L.R.C.P.; L. C. Hayes, Birmingham Univ., L.R.C.P. Lond., M.B. Birm.; B. G. Goodwin, Birmingham Univ., M.R.C.S., L.R.C.P.; A. S. Cane, Camb. and St. Bart's, M.R.C.S., L.R.C.P., B.A. Camb.; T. H. Dickson, Edin. Univ., M.B., B.Ch. Edin.; K. Comyn, Camb. and K. Coll. Hosp., M.R.C.S., L.R.C.P., B.C., B.A. Camb.; F. R. Laing, Edin. Univ., M.B., B.Ch. Edin.; A. G. Jones, Guy's Hosp., M.R.C.S., L.R.C.P., M.B., B.S. Lond.; J. M. Weddell, Camb. Univ., M.R.C.S., L.R.C.P., B.A. Camb.; P. C. Field, Bristol and Guy's Hosp., M.R.C.S., L.R.C.P.; V. P. Hutchinson, Guy's Hosp., M.R.C.S., L.R.C.P.; T. W. Stallybrass, Newcastle-on-Tyne, M.B., B.S. Durh.; H. G. ## SUMMARY OF RECENT MEDICAL LITERATURE, ENGLISH AND FOREIGN.

*Specially compiled for THE MEDICAL PRESS AND CIRCULAR.*

**A Case of Bilateral Pelvic Abscess during Pregnancy.**—Donald (*Journ. Obst. and Gyn. Brit. Emp.*, XVI., 1).—The patient was seven months pregnant and for some weeks had looked and felt ill, for a few days she had suffered from severe pain in the lower part of the abdomen with considerable distension and a temperature running up to 103 deg. She was confined of a premature child and improved, but the temperature was still erratic, sometimes over 103 deg. Examined a few days after confinement nothing could be found in the pelvis to account for the symptoms. Three weeks later two rounded swellings, each about the size of a small orange, could be felt at either side of the uterus, giving a feeling of fluctuation. These were subsequently opened through the anterior fornix and a free discharge of pus obtained. The patient improved considerably, but still the temperature kept up, although not so high as it had been. The local discharge soon ceased and the local condition seemed good. A month after operation the patient had a sudden abdominal attack. The abdomen was opened and some free pus found which had evidently come from the right tube which was perforated and very friable. The pelvis was drained and the patient made a good recovery. It is difficult to understand the co-existence of pregnancy with an abscess in the appendages of each side, and the question arises whether there existed a salpingitis before pregnancy or whether there was an infection during the early months of gestation. The history did not throw any light on this problem.

F.

**Primary Chorionepithelioma of the Ovary.**—Fairburn (*Journ. Obst. and Gyn. Brit. Emp.*, XVI., 1).—The patient, æt. 25, was married five years, and had three children and one miscarriage between the first and second child. The placenta had to be removed by hand at the confinement and three weeks afterwards she developed white leg. The child was nursed for 12 months and after weaning menstruation recommenced. The first period was normal, the next followed in three weeks, and from then there was continuous slight loss nearly every day, at no time was this loss excessive or such as to suggest that there had been a miscarriage. This state of affairs continued for nine months when she had an attack of influenza. When she began to get about pain developed in the left side and lower part of the abdomen. About one month later a tender lump was noticed on the left side. On opening the abdomen the tumour was seen covered with a white capsule, it was very adherent, especially about the level of the pelvic brim and burst during its separation allowing the escape of material so like blood clot that it at once suggested ectopic gestation. When isolated it was found to be a growth of the left ovary. Microscopically the greater part of the growth was found to be made up of blood clot fibrin and necrotic tissue. The chorionepitheliomatous structure is seen best in portions taken from just under the capsule. Although the patient had been pregnant four times there is no history to indicate anything of the nature of cystic mole or of chorionepithelioma elsewhere. The uterus and vagina were apparently free, and the fact that no other growths have occurred, though over two years have elapsed since operation, seems to be proof that the growth was solely and primarily one affecting the left ovary. The writer compares his case with two others reported by Assmuth from Tübingen, and by Iwase from Munich Frauenklinik. He would accept Pick's view as to the possible origin from the transportation of villi from a normal placenta,

as his case and the two referred to were multiparæ, and in two of them manual removal of the placenta had to be practised in the labours immediately preceding the commencement of symptoms.

F.

**A Short Experience of Scopolamine Morphine Narcosis in Labour.**—Croom (*Journ. Obst. and Gyn. Brit. Emp.*, XVI., 1).—The experience extends over 62 cases. As to the dosage, at first 1/400 of a grain of scopolamine and 1/6 grain morphine was given, but these cases were found to be unsatisfactory, the patients all complained of excessive thirst. The effect upon the child was absolutely nil. Then doses of 1/200 scopolamine and 1/6 morphine were tried. The result was a greater diminution in the painfulness of the contractions, and the patients slept in the intervals between the pains, the children were in all cases born vigorous. Afterwards the dose was increased to 1/100 of a grain with 1/6 and the results were much more satisfactory. The painfulness of the contractions was markedly diminished, in some cases abolished, the patients slept soundly in the intervals between the pains and in most cases for one or two hours after the completion of labour. 70 per cent. of the children in these cases were born vigorous, 27 per cent. required slight reviving and 3 per cent. required thorough resuscitation. No children were lost. With the doses of 1/200 or 1/100 there were no complaints of thirst as with the 1/400 dosage. In 37 cases, one injection of the drugs was sufficient. In the other 25 cases one or other or both drugs were repeated in doses varying in the case of scopolamine from 1/400 to 1/100. The repetition of the scopolamine prolonged and slightly deepened the effects upon the mother and child, but the repetition of the morphia caused a much more distinct increase in the effects, particularly on the child, so much so, that latterly the repetition of morphia was entirely given up. The drug was mainly given in the second stage of labour and had a three-fold result, it acted as a soporific, it produced narcosis and in some cases complete anæsthesia, it abolished remembrance of the suffering during labour. In two cases with two injections of scopolamine forceps were applied and the patients delivered without any suffering. In the 63 cases chloroform was administered in 10, of these 4 were forceps cases, two required repair of the perinæum, one was for version, one was a rickety flat pelvis with a breech, and one required chloroform, on account of the patient becoming very noisy, another on account of extreme pain towards the end of the second stage. The only untoward effect was that the child was often born sleepy and almost comatose and remains so for some time after birth. The child is not actually still-born, but it breathes only slowly, does not cry, and has all the appearance of being under narcotic influence. There may, perhaps, be a slight tendency to post-partum hæmorrhage. In three cases that was noticeable, though not to any dangerous extent. None of the cases were totally insusceptible to the drug. Except in cases which responded markedly to the drug, it was distinctly desirable to give chloroform if anything in the nature of operative interference is necessary. As regards the effect on labour the drug did not seem to hasten or delay its progress. In patients who are physically weakened and unfit, the method may be accompanied by some risk, and such cases require to be carefully watched all through. For an ordinary case the best dose was 1/200 scopolamine plus 1/6 morphine, and the scopolamine may require to be repeated in one and a half or two hours in 1/200 of a grain dose.

## NOTICES TO CORRESPONDENTS, &c.

Correspondents requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

### SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12. Messrs. Dawson and Sons are our special agents for Canada.

### ADVERTISEMENTS.

For ONE INSERTION:—Whole Page, 25; Half Page, 23 10s.; Quarter Page, 21 5s.; One-eighth, 13s. 6d. The following reductions are made for a series:—Whole Page, 13 insertions, at 23 10s.; 26 at 23 3s.; 53 insertions at 23, and pro rata for smaller spaces. Small announcements of Practices, Assistances, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

ORIGINAL ARTICLES or LETTERS intended for publication should be written on one side of the paper only and must be authenticated with the name and address of the writer, not necessarily for publication but as evidence of identity.

CONTRIBUTORS are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland to the Dublin office, in order to save time in reforwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

A. K. C.—(1) Thank you for note and compliment. (2) There are about 25,000 deaf mutes in England. Under modern methods of education it is possible to train these persons to a high intelligent pitch, and to enable them to apprehend and to express complicated abstract ideas in a most astonishing way. You had better apply to the Secretary of the British Deaf and Dumb Association.

### A PAUPER OBJECTION TO COLOUR.

A LEICESTERSHIRE PRACTITIONER.—We have perused the remarkable protest signed by fifteen pauper patients of the Lutterworth Union and presented to the Local Government Board. It protests against the action of the local guardians in appointing Dr. J. C. Bhukerchagi, a native of India, as Medical Officer to certain districts within their Union. We are glad to see that since your letter reached us, the guardians, having had an opportunity of seeing the petition in question, replied by a unanimous vote of confidence in their officer. Any other course would be, in our opinion, not only impolitic, but unjust to the last degree. At the same time it is obvious that anyone starting practice under peculiar conditions of the kind in point, must be prepared for various rebuffs, especially from ignorant and prejudiced persons.

R. S. MCGUBBIN.—The case is indeed a good one. It would be well to apply to the various charitable agencies, founded for the benefit of the families of deceased medical men. Every married practitioner in the metropolis should certainly join the Royal Medical Benevolent Fund.

### CORONERS AND DEATHS FROM ANÆSTHETICS.

A SHORT interim report has been issued by the Departmental Committee, appointed to inquire into the law relating to coroners and inquests and the practice of their courts. The report presents the evidence so far given with regard to deaths in connection with anæsthetics and from the use of flannellette clothing. The important question of deaths under anæsthetics will be further investigated, and some time will probably elapse before any definite conclusions are arrived at.

MR. J. W. (Bradford-on-Avon).—Your communication contains such absurd statements founded on wrong premises, that it would be an insult to our readers to insert it.

DR. K. G. W. is thanked for the card of invitation, which we hope to be able to accept. In the present holiday season, however, it is not always feasible to send a responsible representative.

### KISSING THE BOOK VERSUS THE SCOTCH LAW.

A LIVERPOOL correspondent writes us that a change in the method of taking the oath in Courts of Law appears to be making progress. It may be recollected that some time ago the members of the Liverpool Medical Institution, on the initiative of Dr. Fred Lowndes, passed a resolution condemnatory of the "kissing the Book," and in many cases dangerous custom of "kissing the Book." This resolution was carried into practice at the recent assize, when in one of the cases tried before Judge Hamilton, in which medical evidence was required, three medical men requested to have the oath administered in the Scotch way. The change is a very desirable one, and if the medical men themselves practice what they preach, the thinking portion of the community will not be long in following their example.

W. B. PHILLIPS (Croydon).—Last week a Bill was introduced into the House of Commons by Mr. Peel with the view of enabling the Metropolitan Asylums Board, in conjunction with the Commissioner of Police of the Metropolis, to establish an ambulance service for the County of London.

## Appointments.

IRELAND, ARCHIBALD EDWARD, M.R.C.S., L.R.C.P.Lond., D.P.H. Oxon., Medical Officer of Health and Government Bacteriologist, Suva, Fiji.  
LLOYD, BRIMLEY R., M.B., B.S.Lond., D.P.H., Medical Inspector of Schools at Sheffield.  
NASH, E. H. T., M.R.C.S., L.R.C.P.Lond., Medical Officer of Health of Wimbledon.  
RUSSELL, R. F., M.B., B.S.Aberd., Certifying Surgeon under the Factory and Workshop Act for the Ollaberry District of the county of Zetland.  
EMRYS-JONES, F., B.A.Oxon., L.M., has been appointed conjoint Medical Officer in charge of the X-Ray and Light Departments of the General and Queen's Hospitals, Birmingham, and Honorary Radiographer to the Guest Hospital, Dudley.

## Vacancies.

City of Leeds Infectious Diseases Hospitals and Sanatorium.—Resident Medical Officer. Salary £120 per annum, with board, lodging, and washing. Applications to the Medical Superintendent, City Hospitals, Seacroft, Leeds.  
Sunderland and Durham County Eye Infirmary, Sunderland.—House Surgeon. Salary £210 per annum. Applications to J. F. Potts, Secretary, Sunderland and Durham County Eye Infirmary, Stockton Road, Sunderland.  
Dorset County Hospital, Dorchester.—House Surgeon. Salary £100 per annum, with board and residence. Applications to W. E. Groves, Valetta, Icenway, Dorchester.  
Brenty Certified Inebriate Reformatory, Westbury-on-Trym, Bristol.—Superintendent. Salary £300 per annum, with board and quarters. Applications to the Hon. Secretary, 34 Westbourne Gardens, London, W.  
Southwark Union, London.—Assistant Medical Officer. Salary £100 per annum, with board, lodging and washing. Applications to Sydney Wood, Clerk, Union Offices, John Street West, Blackfriars Road, S.E.  
Jaffray Branch of the General Hospital, Gravely Hill, near Birmingham.—Resident Medical and Surgical Officer. Salary £150 per annum, with board, residence, and washing. Applications to the House Governor, General Hospital, Birmingham.  
University of Birmingham (Faculty of Medicine).—Professor of Anatomy. Salary £800 per annum. Applications to Geo. H. Morley, Secretary.  
Nottingham General Dispensary (Branch).—Assistant Resident Surgeon. Salary £160 per annum, with apartments, attendance, light and fuel. Applications to C. Cheesman, Secretary, 12, Low Pavement, Nottingham.  
Hamlet of Mile End Old Town.—Assistant Medical Officer. Salary £150 per annum, with board, lodging, and washing. Applications to Benjamin Catmur, Clerk to the Guardians, Guardians Offices, Bancroft Road, Mile End, E.

## Births.

BOXALL.—On Aug. 13th, at Rudgwick, Sussex, the wife of Frank Boxall, M.R.C.S., L.R.C.P., of a daughter.  
PRINS.—On August 4th, at the Hospital Bungalow, Galle, Ceylon, to Dr. and Mrs. Lorenz Prins—a daughter.  
ROBERTSON.—On August 10th, at Grand Turk, Turks Islands, B.W.I., the wife of T. R. Robertson, M.B., Ch.B., of a son. (By cable.)  
SEALY.—On August 1st, at Loralai, Beleuchistan, the wife of Major Sealy, I.M.S., of a son.  
STONE.—On Aug. 18th, at 30 Nevcrn Square, London, the wife of Major C. A. Stone, R.A.M.C., of a daughter.  
WOLSELEY-LEWIS.—On Aug. 13th, at The Asylum, Maldstone the wife of Dr. Wolesley-Lewis, F.R.C.S., of a daughter.

## Marriages.

ALCOCK-BEARDMORE.—On Aug. 11th, at the Parish Church of Ripple, Kent, Frank Alcock, of Lincoln, M.D., son of the late John Alcock, M.R.C.S., J.P., Staffs., and of Mrs. Alcock, May Bank, Stoke-on-Trent, to Gladys Leslie, only daughter of Rev. Henry Leslie Beardmore, M.A., Rector of Ripple.  
KIDD-BURTON.—On Aug. 12th, at St. Cuthbert's, Philbeach Gardens, London, Archibald William Lyle Kidd, only son of the late Archibald Napier Kidd, M.R.C.S.I., Armagh, Ireland, to Francis Sophia, only daughter of the late Joseph Stewart Burton, M.R.C.S., L.S.A., of Blackheath and Reigate.  
STEWART-HULME.—On Aug. 11th, at All Saints' Church, Marple, George Irvine Thompson Stewart, M.B., F.R.C.S.Eng., youngest son of Sir David and Lady Stewart, Banchory Deuinick, Kincardineshire, to Gertrude, third daughter of the late James Hulme, Esq., of Brabyns House, Marple, Cheshire.  
TEICHMANN-HARBORD.—On Aug. 11th, very quietly, at St. Margaret's, Westminster, Oscar Teichmann, M.A., M.R.C.S., L.R.C.P., son of Emil Teichmann, of Sitka, Chislehurst, Kent, to Edith Henrietta, daughter of the late William Harbord, of Liverpool.

## Deaths.

DAVIS.—On Aug. 11th, at his residence, at Walton-in-Gordano, Clevedon, Somerset, Theodore Davis, M.D.Lond., F.R.C.S. Eng., aged 75 years, son of the late Dr. Theodore Davis, of Clevedon.

No. 8.

## NOTES AND COMMENTS.

### Vaccination and Compensation.

AN anti-vaccinationist correspondent sends us some information of a case which shows an interesting anomaly in the laws which govern the land. It seems that a milkmaid acquired cow-pox in the pre-Jennerian fashion namely, by milking cows. Against the farmer she claimed damages for the injury inflicted on her, with the result that she was awarded £20. In the absence of precise details as to the exact nature of the disease and of the legal process involved, we take the facts as stated, and it cannot but be admitted that it is an odd state of things that, whereas the law lays down that it is the duty of every person to be vaccinated, it should be considered an actionable wrong for a person to become accidentally vaccinated by contact with a man's cows. The logical reasoning would seem to be that if the milkmaid suffered any loss of employment through the inoculation of the hand, that would be set off by the advantage she gained by being rendered immune to small-pox infection for a term of years. If this action became a precedent, perhaps we shall one day see infants suing the public vaccinator by their "next friend" for causing them needless annoyance and suffering in the pursuit of their legitimate occupations of sleeping and feeding.

### Welsh Bone-setter.

IN a case reported from Wales last week there is much food for reflection in connection with unqualified practice. A farm servant was knocked down by a horse and sustained a compound fracture of the thigh. A medical man was sent for, but the messenger was stopped when it was thought the thigh was fractured, and a bone-setter was summoned instead. A few days later the medical man was asked to attend as the man was not going on well, and on arrival he found the patient at the point of death. At the inquest which ensued he gave evidence, saying that the thigh was tightly bandaged, the parts above being blue and swollen, while the leg below was swollen, cold, and pulseless. Underneath the bandage were three pieces of cardboard "embedded in the skin" and a piece of wood. There was also a discharging wound. Death ensued shortly afterwards of acute blood-poisoning following compound fracture of the thigh. After the bone-setter had given evidence, in which he said that he had treated hundreds of broken limbs, but never one like this, the Coroner, in his summing-up, said that if a person, qualified or unqualified, undertook to look after a case, he was bound to exercise a proper amount of diligence, and if the jury thought the bone-setter had been guilty of gross ignorance and neglect they should return a

verdict of manslaughter. After retiring, the foreman said they were unanimously of opinion that no blame whatever attached to the bone-setter. On these circumstances we can only say that if a jury is unanimously of opinion that no blame whatever attaches to a person who undertakes a case like this and treats it in the manner described, no powers the legislature might give would secure the suppression of unqualified practice.

### Insurance and Health.

A REMARKABLE departure from the ordinary routine of life insurance is reported from New York. "A big insurance company"—the name is not stated—has, it is said, decided to establish a health bureau, including free medical examinations, with the idea of prolonging the lives of policy-holders, and to develop original research into the prevention of disease and the discovery of threatened disease in time to effect cure. Medical men have been engaged to serve on the staff, and a circular letter is being sent round emphasising general rules for retaining good health and improving bad. Further, we are told, other companies are likely to follow suit, "when it is shown that both insured and insurer are benefiting by the health bureau." Pessimistic it may sound to dwell with too much stress on the word "when," and if the scheme is really started we shall watch the experiment with great interest. We do not understand how it will work without conflicting with the interests of the general practitioners, who are hardly likely to be pleased if they are deserted by their patients in favour of the bureau doctors. Nor, unless we are to understand that the latter are specially endowed, are they likely to be able to do much more to nip disease in the bud than their fellows.

### Preventing Disease.

IT is hardly probable that healthy people who have insured their lives will submit to periodical medical examinations on the chance of something being found wrong with them which may be alleviated by early treatment; human nature being what it is, most men would rather not be aware that their urine contained a trace of albumin, let us say, than that constant search should be made to discover it. Moreover, a person constantly under medical supervision would have less chance of taking out a further policy than a person not so supervised, for any defect discovered, even if cured, would tell against him. It is not our business to criticise the business side of such an insurance development, but we candidly do not see how the office is ever to see its money back. Regularly to examine all policy-holders and to advise them would need a large and expensive staff throughout the States, and it is to be feared that,

most of the interviews being routine formalities, there would be a great tendency for the examinations to become perfunctory. Still, there is no necessity, in our view, to contemplate the minor disadvantages, as it is expecting too much even of the neurotic American to think that he will run his course under the watchful eye of a doctor not even chosen by himself.

#### An Enemy of the People.

READERS of Ibsen will remember how Dr. Thomas Stockmann, medical officer of the baths of his native town, made the discovery that the water of the baths was being poisoned by sewage contamination. Like an honest man he set himself to remedy the matter, but to his intense surprise found himself hampered by the reluctance of the Burgomaster and other prominent citizens to permit any knowledge of the facts to become public, since the welfare of the town was dependent on the reputation of her baths. The town rose against him, and he was denounced as "an enemy of the people." A similar series of events occurred not long ago in San Francisco when medical men, who ventured to diagnose cases of plague correctly, were denounced and driven from their employment. In somewhat similar fashion the exertions of the Countess of Aberdeen and those working with her to stay the progress of tuberculosis in Ireland have roused violent opposition in several quarters. It is asserted that, owing to the publicity given to the condition of the country by Lady Aberdeen's exertions, tourists are afraid to come to the country, that hotels are consequently losing heavily and that Irish servants are unable to obtain employment in England. We have no reason to believe that there is any truth in these loud complaints, but even if there were it would be a small price to pay for freedom from tuberculosis. There is good reason to believe that even already the exertions of the last two years have borne fruit in the saving of life, the Registrar-General's returns for last year showing a decided improvement on those for recent years. It is not to be forgotten, however, that the rate of mortality is still one of the highest in Europe.

## LEADING ARTICLES.

### "CHRISTIAN SCIENCE" AND MRS. EDDY'S MONEY.

THE growth of science of any kind appears fated by some immutable law of life, to be haunted by the untiring shadow of charlatanism. Of all the astonishing pseudo-sciences that thrive at the expense of the community, there is none more fatuous and amazing than the grotesque gospel known as Christian Science. Its foundress, Mrs. Eddy, apparently chose that name on the principle of *lucus a non lucendo*, inasmuch as it would be impossible by any process of correct, that is to say, of logical, thinking to demonstrate its doctrine as being either Christian or scientific. So far as Christianity is concerned, we believe it is admitted by the sect that their "bible"—to wit, Mrs. Eddy's book, "Science and Health," sold at prices varying from 12s. 6d. to 25s.—is not permitted to be translated into foreign languages. In other

words, a large proportion of the inhabitants of the world—assuming that such a limitation exists—are deprived of the opportunity of becoming acquainted with the doctrines of a creed which believes the book in question to be essential to the present welfare, if not to the future salvation of mankind individually. That sort of selfishness certainly does not coincide with the spirit of universal charity and goodwill to all men that forms one of the most attractive features of christianity. Not only were the early Christians instructed to sell all they had and give to the poor, but they were taught that to preach the gospel was a first duty. There is hardly any more remarkable fact in human history than the way in which christian doctrines and christian literature have reached every clime under the sun. We are not for the present concerned with the truth or otherwise of the doctrines of christianity, but we claim the right to ask on what grounds any particular sect should assume a title that has become sacred to a great portion of the world. So far as we can gauge the question, the assumption of the name "Christian" by Mrs. Eddy and her followers is indefensible, if only because of the high price and limitation of the literature setting forth the tenets of their creed. Indeed, there appears to be no essential difference between this mis-called science and any other form of false medical practice worked on any ordinary money-making basis. Like the proprietors of any familiar "cure all" nostrum, Mrs. Eddy and her followers profess to cure all human diseases by some mystic process compounded of prayer and faith, applied with some sort of anointing or laying-on of hands, or other rites that, in our opinion, amount to little short of blasphemy. In one case that came before the law courts a few months ago an army officer was allowed to die of an abscess, from which under ordinary medical treatment he would, humanly speaking, have certainly recovered. The moral responsibility for that death, as for all deaths occurring under analogous circumstances, we regard as resting with the administrators of the pseudo-science that has been substituted for orthodox medical treatment. In its essence, Christian Science is simply a form of irregular and therefore illegitimate, medical practice. Those who practise it are paid fees for their services, but in the anomalous state of the British law as regards quack practice, it is difficult to suppress, or even to check, its grotesque rites. From the commercial point of view, there seems to be as much money in this as in other forms of false medical practice. At a recent trial, it was stated that Mrs. Eddy's fortune amounted to some £250,000, of which £200,000 had been given to one charitable institution alone. Unfortunately, the precise sum and nature of the organisation concerned is not known to us, but it would be interesting to learn what form of practical charity coincides with the donor's particular views. Nor is the so-called science of the sect any sounder than its Christianity. All accidents and diseases come under the scope of orthodox medical science, which endeavours to place sufferers from any bodily abnormality under conditions that will restore them, as far as possible, to a normal condition. Mrs. Eddy and her followers however, grasping the bull by the horns,

boldly eliminate surgical conditions, as, for instance, a broken leg, from their field of labour, and reserve to themselves the infinitely more difficult and intricate problems of pure medicine. Needless to say, the chances of recovery of persons suffering from serious but curable complaints, who do not receive skilled medical treatment, are thereby immeasurably reduced. We have spoken out on this matter, as we regard the pretensions of Christian Science as a standing menace to the welfare of society. A few police prosecutions would do much to open the eyes of the people as to the real nature of the cult, and would help to protect persons whose intellectual equipment is not sufficiently strong to enable them to judge aright when faced with the wiles of specious, but wholly foolish and dangerous charlatanism, parading under a thin guise of morality.

#### LUNACY LAW REFORM.

THE Report of the Commissioners in Lunacy for the year, just issued, constitutes the sixty-third of the series presented to the Lord Chancellor. Apart from the usual features of interest and the informing statistical tables, the special feature of this report consists in certain criticisms and suggestions made by the Commissioners on the Report of the Royal Commission on the Feeble-Minded. To adopt, even if it were well to adopt, the recommendations of that Commission *in globo* would entail the passage of a considerable Bill through Parliament, and one which would deservedly give rise to much discussion. In the present state of legislative congestion, such a measure will, we fear, have to wait a considerable time before it sees the light, or, at least, before it has any chance of passing, even under the reformed procedure now adopted. It is a significant comment on our parliamentary system that these pressing matters of social reform should excite so little practical energy and enthusiasm in the breasts of the people, that their parliamentary representatives prefer to waste hours and weeks of precious time by blocking and obstructing, by what are regarded as "legitimate" methods, measures which they object to, but which are destined to pass by the mere weight of a Government majority, if by nothing else, to the exclusion of so many questions tending to the higher civilisation of the country. Foreseeing the unlikelihood of a big and comprehensive scheme passing for some time yet, the Commissioners recommend that some of the more serious anomalies of the present position should be dealt with by short amendments to the existing Acts. The first important matter they would like to see dealt with is the segregation or restraint of some classes of the feeble-minded. Defective women and girls need special care, so that they may be prevented from becoming mothers. To those who have the real interests of the community, present and future, at heart, surely there can be nothing which should evoke more general interest and sympathy. The cruelty to these wretched creatures involved in their violation by unheeding men and boys, and the still greater barbarity of permitting the birth of children tainted with mental defect, should hardly require demonstration, and we need hardly say that we cordially endorse this proposal

of the Commissioners. The next matter is the restraint of the feeble-minded criminal, that is, of the feeble-minded person who turns naturally to theft as a means of sustenance, and whose whole life consists in alternations between gaol and petty crime. A step in the right direction was taken last year by the institution of the indeterminate sentence, but, like most new things, this excellent provision has not found favour with judges, and additional effective administrative means are badly needed for the benefit of the defective criminal. Reform of the Lunacy Commission itself has long been required, and the Commissioners again recommend that their number should be increased by two medical members. As they rightly point out, the legal side is well represented, and, insanity being a disease, the subjects of it need enlightened supervision and treatment of a medical character. Moreover, the study of insanity and research work into its nature and prevention can only be carried out by medical men. For our own part, we say unhesitatingly that we consider the presence of legal members on the Commission as an anachronism. At the beginning their presence was looked upon as a kind of safeguard to the personal rights of the insane, but with the change which has taken place in the whole scheme of dealing with insanity, their retention not only is very costly, but it deprives the Commission of a proportionate number of working members. As every body connected with asylums knows, the "inspection" by legal members is a solemn farce, for they know as little about institution work, administration, and insanity, as the medical members do about conveyancing. A legal adviser is needed for the Commissioners, but they themselves should all be medical men. A lingering remnant of the ineffectiveness of lunacy law is presented by the institution of the Judge and Masters in Lunacy, with the Chancery Visitors, for the management of the property of all classes of mental defectives. Here, again, is a most expensive legal staff before whom proceedings in the case of the estates of lunatics is heavy and burdensome and superfluous. Most of the insane are people of small means, and the administration is most costly. The two medical visitors should be transferred to the Commissioners' staff, and the business side put under the Public Trustee. The Commissioners recommend the former step, but, oddly enough, they suggest that the Chancery Division of the High Court should be substituted for the Judge and Masters. Surely the machinery of the Public Trustee's department is precisely what is required to deal with the estates, and the cost is trifling, generally averaging from one to two per cent. on all transactions. If the Lord Chancellor can see his way to institute these pressing reforms, he will accomplish much to distinguish his tenure of office.

#### CURRENT TOPICS.

##### The Hospital Treatment of School Children.

THE treatment of defective school children is one of vast practical importance to medical men. Unless some decisive steps are taken to prevent local authorities from sending their patients to the voluntary charities, a most unjust addition will be

made to the gratuitous work already performed by the profession concerned. Worst of all, the injury to general practitioners will be wrought through the agency of their professional brethren on the honorary staff of the hospital. The London County Council has entered into arrangements with a few of the hospitals for the treatment of a certain proportion of defective children. This action was formally disapproved by the Annual Representative Meeting of the British Medical Association. That body has not allowed the grass to grow under its feet, but has promptly circularised members of the honorary medical staffs of the metropolitan medical charities, drawing attention to its resolution, and expressing a hope that those addressed will do all in their power to prevent such an abuse of the voluntary charities. This practical step is a move in the right direction, as it tends to convert a pious resolution into a polite pressure. It remains to be seen whether the members of honorary medical staffs will venture to ignore the only authorised and collective voice of their profession that is available. The boards of hospitals are apt to treat with contempt the interests of the outside medical profession. It is to be hoped that the present action of the Association Representatives will inaugurate a new era by instituting a certain amount of control over medical charities through the medium of their honorary staffs. The success or otherwise of this most desirable consummation will depend on the loyalty of those gentlemen to their professional brethren.

#### Motor Ambulances in Towns.

THE value of motor ambulances in great modern towns is almost incalculable. The positive saving in human suffering, and, now and then, in human life, resulting from a good organisation of the kind, is more or less self-evident. Now that the use of the telephone is becoming universal in busy quarters, there need be little difficulty in summoning an ambulance. In London, curiously enough, the provision of an up-to-date system of the kind is behind that of various other large towns in various parts of the kingdom. In his evidence, last week, before a Committee of the House of Commons, Sir William Collins threw some valuable light upon the subject. Of recent years there has been an increase, according to the police returns, of the number of persons killed and injured in street accidents in the metropolis. In 1891 the figures were 5,784, but in 1905 they reached 11,850; in 1906, 14,278; and in 1907, 17,035—an increase of 62 per cent. in three years. It is a significant fact that of those injured in the London streets, no less than 60 per cent. conveyed to hospital are carried by cab or van, "often a most unsuitable and dangerous arrangement." At present it is suggested that, as in the case of the City of London proper, the call should be given by the police only, while in suburbs the public would be able to give the requisite summons. In the City, however, the police are under the control of the Corporation, whereas in greater London the control is vested in the hands of the Home Secretary.

#### Ice-Cream.

ON August 6th, at Marylebone Police Court, the hearing of a charge of permitting ice-cream to be manufactured under insanitary conditions disclosed a revolting story. The defendant occupied a shed and two rooms, one of which, where the cream was manufactured, was described as "partly water-closet, and partly dustbin," having besides in one corner an open

gully leading to a drain. A quantity of hot stuff for making the cream was found in one bed-living room in two large uncovered tins. This room was described as filthy; it was occupied by two adult females and one male during the night, and by one adult male during the day. The finished "cream," it was further stated, was retailed in the streets, and there exposed on a barrow in open pails to further contamination from an atmosphere loaded with foul dust. The magistrate expressed the hope that people reading this case would think before purchasing "ice creams" of such quality, and "save themselves from typhoid fever or something of that sort." As the customers for street-vended ice-creams are almost entirely children, it is not likely that the magistrate's suggestion will have much effect. It would be an advantage if, instead of the maximum fine of 40s., which was imposed in this case, the law would allow of a sentence of imprisonment with hard labour upon wilful offenders, whose methods are likely to be followed by widespread injury to the public health.

#### Quis Custodiet Custodes?

A LETTER in leader type in a prominent position in the *Times*, and having, besides, the intrinsic value due to literary purity, commands attention and respect, whether or not the writer withholds his name; and we cannot doubt the truth of a story published under these conditions in a recent issue of our contemporary. The writer stated that he had occasion to call in three medical men within the last few months. Two of them were practitioners eminent in England, the third a specialist famous on the Continent. Each of them made use of a clinical thermometer, taking it from its case, fingering it, inserting and leaving it in the customary way in the patient's mouth, and after withdrawing it, putting it back uncleansed into its case. This incident is one of a kind which, during a recent trial in the High Court, was characterised by the judge as a "true Molière." One can picture the pompous doctor holding forth in learned terms on the dangers of sepsis, whilst plunging into the open mouth of his awe-stricken victim a filthy instrument, the vehicle for conveyance of a dose of germs, the virulence of which the learned physician had just described. It is a bit of true comedy, looked at from one point of view, but calculated to produce a smile on the wrong side of the face of the great bulk of medical men who take their profession seriously, or, perhaps, even too seriously.

#### Sick and Wounded Territorials.

THE Secretary of the War Office has within the past few days issued to the Territorial County Associations throughout the country a "scheme for the organisation of voluntary aid in time of invasion." The scheme is the outcome of a conference of the Army Council with the British Red Cross Society and the chairmen of certain county associations. The scheme develops fully the suggestions put forth in the Circular Memorandum issued in May last year, upon which we commented at the time, and sets out in explicit terms, and with precise instructions, matters with which, since the subject is a new one, the public is not familiar. It is hoped that county associations will place themselves in communication with the Red Cross Society, with a view to initiating the formation of voluntary aid detachments, if it is not the wish of the associations themselves to undertake their formation and training. The scheme is avowedly modelled upon those existing in Germany and

Japan. It is stated that the medical organisation of the Territorials is sufficiently complete to meet the immediate requirements of the troops on the march and in action, but lacks several of the parts provided for in all home defence armies. The requirements most urgently called for are: 1st, Trained corps for organisations connecting field ambulances with railway lines ("clearing hospitals"); 2nd, trained corps organised for rest stations or temporary hospitals; 3rd, trained corps for the expansion of general hospitals; and, finally, there is to be considered the choosing of the necessary hospitals. In order to provide a *personnel* for all the duties described, it is suggested that "voluntary aid detachments" of the British Red Cross should be organised in each county. The detachments would consist of both men and women, to the women being, of course, allotted the work of nursing and of preparing food. The aim will be to enable local detachments to make use of local resources for improvising accommodation and transport of wounded, and for providing for them temporary care and treatment until they reach the general hospitals. The scheme is thoroughly practical; to take part in it will bring a new interest into many incompletely occupied lives, and it need not be doubted that the patriotic spirit which has so successfully established the Territorial Forces will win success for this necessary part of its organisation.

#### Hop Substitutes in Beer.

THE subject of beer-brewing, and the materials used in the process, is ably dealt with in the recently-issued quarterly Report of the Kent county analyst, Dr. M. A. Adams. Dr. Adams expresses the opinion that there is nothing prejudicial, or even unreasonable, in the use of certain malt substitutes, but does not consider the case of hops as quite the same. He declares that hops flavour the beer as no others substance can flavour it, and by their action upon certain of the albuminoid materials of malt they act as preservatives. There are many agents, like quassia, for instance, that can impart bitterness, but it is not the wholesome bitterness of the hop. Dr. Adams utters a vigorous protest against the use of antiseptics like salicylic acid for preventing the beer from going bad. This acid is a potent drug that should be employed only by the physician as a remedy in certain maladies; it has no rightful place as an "article of diet." The Kent County Council have adopted Dr. Adams' suggestion that it should be made an offence under the Food and Drugs Act to use any substance other than hops for the bittering of beer, or any chemical substance such as salicylic acid as a preservative, and the Council have resolved to communicate with the Government on the subject. In the meantime, until new legislation is passed—probably a remote contingency in the present state of parliamentary business, all the ingenious manufacturers able profitably to turn out beer containing little malt and no hops will no doubt make the most of their opportunities. If the liquor be palatable, and taken in moderate quantity only, it may not, at any rate, prove more injurious to health than the genuine article; and with this feeble consolation we must, for the present, be satisfied.

#### PERSONAL.

We understand officially that H.M. the King has been pleased to give effect to the representations of the General Council of Medical Education and Registra-

tion that it is expedient to confer on the registered practitioners resident in England and Wales the power of returning an additional member to the General Council. This addition, however, will not be made until the next ensuing general election of direct representatives.

AN interesting announcement in connection with the new "Red Cross" organisation is that Princess Christian has accepted the presidency of the Berks County Section of the new Territorial branch of the St. John Ambulance Association. Under the scheme recently published by the War Office and the British Red Cross Society, every candidate for the voluntary aid detachments must be in possession of the St. John Ambulance first aid and nursing certificates.

THE Commissioner of Police has appointed Dr. F. E. Cane a divisional surgeon to the police of Edmonton district in succession to Dr. W. Jones.

DR. DOUGLAS ARGYLL ROBERTSON, Hon. Surgeon Oculist to His Majesty the King in Scotland, Consulting Ophthalmic Surgeon, Edinburgh Royal Infirmary, left estate valued at £30,002.

DR. W. BEVAN LEWIS, Medical Superintendent and Director of the West Riding Asylum, Professor of Mental Diseases in Leeds University, has been elected President of the Medico-Psychological Association of Great Britain and Ireland.

DR. W. GIBSON, J.P., has been appointed, under the Marine Department of the Board of Trade, Sanitary Surveyor and Medical Inspector of Emigrant Ships at Belfast, a post held by Professor Sinclair until the beginning of the present month.

DR. ANDREW JAMES DUNCAN, of Nethergate House, Dundee, Consulting Physician and Ophthalmic Surgeon to the Dundee Royal Infirmary, who died on July 7th, aged 66, left personal estate in the United Kingdom valued at £23,612.

MEMBERS of the General Medical Council and others who have attended its sittings, will learn with regret of the death, at the age of fifty years, of Mr. Sydney Lushington, barrister and standing counsel to that august body.

AT the Cheltenham Liberal Club, Dr. Richard Davies, one of the representatives of the North Ward on the Town Council, was presented with a motor-car and illuminated address from sympathisers and constituents and fellow-townsmen grateful for his past services.

THE DUKE OF DEVONSHIRE will preside at the Poor-law Conference for the counties of Derby, Leicester, Lincoln, Nottingham, and Rutland, at the Town Hall, Buxton, on October 21 and 22. Papers will be read on the Report of the Royal Commission on the Poor-laws in relation to rural unions, the proposed abolition of boards of guardians, and district nursing of the aged and destitute.

THE Management Committee of the Glasgow and District Branch of the National Association for the Prevention of Consumption have unanimously appointed Dr. James W. Allan, Glasgow, a former Superintendent of Belvidere Hospital, Glasgow, to the position of Resident Physician at the Sanatorium, in lieu of Dr. Beaumont Percival, who had accepted an appointment abroad.

THE late Dr. Rayner Batten, of Gloucester, has left estate of the value of £46,973, and Dr. E. Wearne Clarke, of Chesterfield, £7,261. The latter bequeathed the ultimate residue of his property to the Senatus of the University of Edinburgh, upon trust to found and endow a bursary to be called the "Wearne Clarke" bursary, "in honour of my University and for the help of some others that come after me in my profession."

# A CLINICAL LECTURE

ON

## FEEBLE-MINDED CHILDREN. (a)

By A. F. TREDGOLD, L.R.C.P.Lond., M.R.C.S.Eng.,

Medical Expert to the Royal Commission on the Feeble-Minded; Consulting Physician to the National Association for the Feeble-Minded, &c., &c.

### PART I.

GENTLEMEN,—As you are all aware, children differ enormously in their mental capacity. On the one hand, there are those who are so far ahead of the average that they astound us with their precocity, and there are probably no branches of science or art which have not possessed their infant prodigies. At the other extreme we see idiotic children who are so deeply deficient in mental capacity that they may almost be described as mindless. There is, of course, no difficulty in recognising that the condition of these latter is abnormal and pathological, but, in view of the fact that they are apparently connected by means of a regular series of gradations with those of precocious development, it becomes by no means an easy matter to say where this pathological change begins and where the physiological condition ends. Consequently, our first task must be to define what we mean by the feeble mind, and to do this it is necessary that we should have a definition of the normal mind.

Now, mind is exceedingly complex, and the mental capacity even of those whom we have no difficulty in recognising as normal varies within very wide limits. Since, however, the only manifestations of mind are movements or inhibition of movements, it is upon the nature of these that we must depend for our definition, and in particular it is upon the character and extent of those movements by which an individual conforms to his social environment—that is, upon his conduct and general behaviour—that we must form our judgment as to the health or disease, the normality or abnormality, of his mind.

Using this criterion, I have ventured to define the normal mind as “a degree of mental capacity sufficient to enable its possessor to perform his duties as a member of society in that position of life to which he is born.” This standard we must look upon as the irreducible minimum, and any falling short of it must be considered as abnormal and pathological.

Now there are three main conditions—three forms of disease of mind—which fall within the category of the pathological. These are insanity, dementia, and amentia or mental deficiency. Accepting the axiom that the neurones of the brain constitute the anatomical basis of mind, we may regard insanity as the result of a perverted function of those neurones, dementia as being caused by their decay, and amentia, or mental deficiency, as the clinical expression of their imperfect or arrested development. To make use of a homely simile, we may say that the ament is a person who has never possessed a mental banking account; the lunatic is one who is in temporary difficulties; whilst the dement is in a state of inextricable bankruptcy. It is, of course, with the mentally defective only that I am concerned to-day; but I mention these facts because it is very desirable that we should have a clear conception of the relationship of this to the other forms of mental disease.

But, just as normal minds vary very greatly in their capacity, so do minds which are defective, and the order of amentia ranges between persons who, on the one hand, are but little removed from the normal, to, on the other, the most profound idiots. Since these two extremes are connected by insensible gradations, any differentiation must be looked upon as an arbitrary one; but for convenience of description and administration, we may divide the mentally defective into three classes.

The lowest class consists of individuals so defective

as to be lacking in the power of self-preservation. This degree is termed idiocy, and the idiot is defined as “a person so deeply defective in mind from birth or from an early age that he is unable to guard himself against common physical dangers.”

In the next degree, known as imbecility, this power of self-preservation is present, but there is no capacity for systematic or sustained work; accordingly, the imbecile is defined as “one who, by reason of mental defect existing from birth, or from an early age, is incapable of earning his own living, but is capable of guarding himself against common physical dangers.”

Lastly, in the third or mildest degree of mental defect, we have a capacity so far in advance of the others that not only may certain kinds of work be undertaken, but, under proper supervision, the individual may actually pay for his keep, although he can never compete on equal terms with his normal fellows, nor can he lay out the money he earns or manage his affairs with the ordinary prudence of a normal person.

Literally, the term feeble-minded is applicable to each and all of these degrees, and in America it has this general significance. For some time, however, it has been customary in this country to restrict it to the mildest degree, and it is to this latter class that it is now usually applied.

The feeble-minded, then, are persons (children or adults) who suffer from the mildest degree of mental deficiency, and although some of the least defective members of the class seem to approach very closely to the normal, it is necessary to remember that they are really morbid and pathological specimens, and separated from even the least intellectually gifted of the normal by a great and impassable gulf. That this is so is shown by their absolute incurability, and by the fact that they possess similar ætiological and anatomical features to the idiots and imbeciles. In fact, mental deficiency is not a mere subtraction in varying degree from the normal, but stands on an entirely different footing.

I do not propose to weary you with any detailed account of the anatomy of these feeble-minded children; but there are some points, not devoid even of general interest, which I must place before you. What the precise relationship is between mind and brain we do not know, and metaphysical speculation on this matter would take us too far away from our subject; but this much is clear, and generally accepted, that in some way or other the brain is the organ of mind. Consequently, we should expect the defective mind to be accompanied by a defective brain.

In idiots and imbeciles the whole brain is usually small, and presents readily recognisable anomalies of form and consistence. Occasionally it is larger, but I do not think I have ever seen the brain of a person suffering from severe mental defect which did not present some marked pathological condition or anomaly of development which at once distinguished it from that of a normal person. In cases suffering from the mildest degree of deficiency—namely, feeble-mindedness—these naked eye changes may not be so obvious, and such a brain may appear to be quite normal. It is here, however, that we are helped by the microscope.

In recent years a considerable amount of work has been done in the microscopical examination of the defective brain, and, speaking generally, three main conclusions have been arrived at. Firstly, the defective mind is accompanied by a defective development of the cortical neurones. Secondly, this imperfect development is most marked in certain regions of

(a) Delivered at the Medical Graduates' College, July 7th, 1909.

the brain. And, thirdly, the amount of change discoverable under the microscope is, as a rule, directly proportionate to the degree of deficiency observed during life. As you are aware, the brain of a newborn child consists of a gelatinoid substance in which are embedded myriads of embryonic ganglion cells or neuroblasts. In the course of time these neuroblasts undergo structural development, and they finally compose the definite cortical layers, the cells of which differ in structure according to their particular function. If the brain of a normal person of mature age be examined, a few undeveloped neuroblasts may still be found amongst the fully developed cortical cells, showing that, even in regard to the highest type of cell which has yet been evolved, Nature still provides lavishly, and in excess of any ordinary demands. Another explanation, which I throw out to the pedagogue, is that these undeveloped neuroblasts in the normal brain may be the consequence of the inadequacy of our present educational methods.

In the defective brain, on the other hand, we still see apparently healthy, fully-developed cells, as well as incompletely developed neuroblasts, but, instead of the former being in the majority and the neuroblasts being few and far between, these conditions are reversed, and we find a comparative paucity of healthy cells and an abundance of imperfectly developed neuroblasts. Moreover, the total number of cortical cells is smaller, and, instead of being arranged in an orderly manner, they are often extremely irregular and haphazard in their arrangement; instead of their apices pointing uniformly upwards, it is quite common to find the cells sideways, or even upside-down.

Such incompletely developed cells are to be found in practically all the cell layers and regions of the cortex; they are, however, most marked in the layers of the medium and small pyramids, and they occur in much greater number in the prefrontal and parietal lobes of the brain. This fact is particularly interesting because it has been found that it is these same layers of cells and fibres, and the same regions of the brain, which are normally the latest to develop and which show the earliest and greatest change in dementia. So that there is good reason for thinking that in the cells of these layers and regions we see the anatomical basis of the highest processes of mind.

We see, then, that in the mentally deficient there is some cause at work interfering with the proliferation and development of the cortical cells of the brain, for these cells are both fewer in number and imperfectly developed. The next question is: What is this cause?

In the course of its development the brain is subject to the action of two forces, intrinsic and extrinsic, in other words, heredity and environment. Ancestral tendencies, acting upon the germinal plasma in a manner we do not yet understand, urge forward the embryonic rudiment along certain lines. The environment, according as it is favourable or the reverse, assists or modifies this developmental march. It cannot be doubted that the environment does have a very considerable effect upon all forms of life which are undergoing rapid growth. We see this in plants, in animals, and in the offspring of man. As physicians, we see daily many examples of the effects of a pernicious environment (using this term to include all external influences, such as food, warmth, air, etc.) in bringing about defective stature, weak and flabby muscles, delicate chests, and many other conditions of imperfect nutrition. Further, we see a similar effect upon the brain, and such cases as Kaspar Hauser, Laura Bridgman, and many others amply demonstrate that cortical development may be interfered with by deprivation of the stimuli which are necessary to it. But these cases are rare, and it is a remarkable fact that although adverse conditions exercise a potent influence upon bodily development, their effect upon cerebral growth seems to be comparatively slight. Apart from accident or definite disease of the brain, to which we shall allude presently, the small number of cases of mental defect which result from external influences are nearly always a consequence, not of deprivation of food and pure air, or other pernicious factors which make up slum life, but of the deprivation of sensory stimuli. The child of the slum,

although often enough of wretched bodily physique, is usually immeasurably superior as regards his mental capacity to the lusty offspring of the agricultural labourer. It is my opinion, therefore, that amongst all the factors of the environment which encourage cortical development, impressions of sight, sound and touch play by far the most important part.

At the same time it cannot be denied that some of those other factors to which I have alluded have an influence in retarding development. Many ill-nourished children are not only dwarfed in their bodies, but also in their minds. The resulting condition, however, is not feeble-mindedness, but simply intellectual dulness. It disappears when the adverse environment is removed, whereas real mental defect is incurable. I have thought it well to refer to this because some people, even some medical men, are apt to think that the environment is an important factor in producing feeble-mindedness. In my opinion this is a fallacy. I have never seen a case of idiocy or imbecility so caused, and very rarely a doubtful case of feeble-mindedness. Many of the so-called defective children attending special schools who are instanced as examples due to faulty environment are not defective at all, but merely dull and backward. A certain proportion of cases, probably about 10 per cent., are, it is true, due to external factors, but these act by bringing about hæmorrhage, inflammation, or some definite disease of the brain whereby the further growth of the cortical cells is arrested. These we shall consider subsequently.

In the great majority of cases of feeble-mindedness it is not the soil, but the seed, which is at fault. The cortical cells fail to attain full development because the germinal plasma is defective from the very beginning. And this inherent defect is due to morbid heredity. I have made careful inquiries into the antecedents of several hundreds of persons suffering from mental defect, and I find that there are three conditions which are so common to these cases that it is impossible for us to look upon the connection as an accidental one. These are:—(1) Antecedent mental defect, insanity, epilepsy, or other serious anomaly of the nervous system; (2) Tuberculosis, and (3) Alcoholism. I do not deny that such conditions may and do occur in the genealogical tree of individuals who are perfectly healthy in body and mind, but in these cases of mental defect it is not a single insane, consumptive, or alcoholic ancestor that we find, but a marked family tendency to one or other of these conditions. To give actual figures, I may say that in my own series of cases of amentia, which embraced the severe as well as the mild grades, over 80 per cent. of the sufferers were the descendants of a pronounced neuropathic stock; 46.5 per cent. showed a family history of marked alcoholism; and 34 per cent. of tuberculosis. There are, of course, other antecedent factors concerned in the production of amentia, for it is a condition the cause of which is rarely single, but I believe these three to be the chief.

I will not attempt here to describe the manner in which these ancestral defects act, but, in view of all the facts, I can come to no other conclusion than that in some way the germinal plasma has been so devitalised by such marked hereditary conditions that it is incapable of normal and perfect development, and the effect is naturally seen in the most complicated, most unstable, and latest acquired tissue—namely, that concerned with mind.

Now, the pronounced grades of defect—that is, idiocy and imbecility—have been known from time immemorial, and they are legally recognised in all civilised countries. Persons suffering from the milder degree of feeble-mindedness have also for long been known as "not-all-there," "not exactly," or by some similar euphemistic term. In this country, however, the legal recognition of this class dates from comparatively recently, and even now, whilst providing for the feeble-minded child, we ignore the feeble-minded adult. The legal cognisance of the feeble-minded child arose in this way. Soon after the passing of the Act which made elementary education compulsory, it began to be noticed that a class of children were attending elementary schools who, although not

imbeciles, were yet so defective in mind as to be incapable of profiting by the ordinary methods of instruction. Inquiries were made by various medical men, scientific and philanthropic societies, and finally a Departmental Committee was appointed. This led, in the year 1899, to the passing of an Act which clearly defined the mental status of these children, and which permitted the local education authorities to provide special facilities for their training.

In the words of this Act, these children are defined as those who, "not being imbecile, and not being merely dull and backward, are defective, that is to say, by reason of mental defect are incapable of receiving proper benefit from the instruction in the ordinary public elementary schools."

From this date, therefore, feeble-minded children acquired a definite legal recognition and became the subjects of interest and importance, not only to the pedagogue, but also to the medical practitioner, upon whom was placed the duty of certification. And it is likely, in view of the recent Report of the Royal Commission, that the next few years will see further legislation regarding this class, whereby the duties and responsibilities of medical men will be considerably increased.

The number of these children varies somewhat in different localities, owing to causes into which I will not enter. On the whole, however, they compose about 8 per 1,000 of the school population of the country, and I estimate that in England and Wales their total number is over 50,000.

Mentally deficient children are divisible into two groups, which have usually been termed "congenital" and "acquired." The term congenital is applied to those cases in which the defect dates from before birth, acquired to those dating from after birth. In my opinion, however, it is unscientific to make use of the period of emergence of the child into the world as a means of differentiating these cases, for an inborn defect may not be revealed until the early years of childhood, whilst an acquired defect may be acquired whilst the child is yet unborn. For these reasons I have proposed to discontinue the use of these terms entirely, and since the real difference is dependent upon whether the defect is the result of a morbid condition of the germinal plasma, or is due to an adverse environment, I have suggested instead the terms "primary" and "secondary." By primary mental deficiency I mean a defect which is due to inherent imperfection of the germinal plasma of such a nature that perfect mental development is impossible. By secondary mental deficiency I mean a condition of arrested mental development, the result of some extraneous factor acting after the fertilisation of the ovum.

It is true that in a few cases this distinction cannot be made, for there are some cases in which both inherent defects and extraneous influences are at work; but, on the whole, most cases can be referred to one or other of these groups without much difficulty, and since primary and secondary cases differ not only in their ætiology, but also in their clinical appearances, such a classification is extremely convenient, as well as scientifically sound.

(To be concluded in our next.)

**NOTE.**—A Clinical Lecture by a well-known teacher appears in each number of this journal. The lecture for next week will be by A. F. Tredgold, L.R.C.P.Lond., M.R.C.S.Eng., Medical Expert to the Royal Commission on the Feeble-Minded; Consulting Physician to the National Association for the Feeble-Minded, &c., &c. Subject: "Feeble-Minded Children" (Part II.).

It has been decided to proceed with the building of an extension to the Acton Cottage Hospital. The designs provide for a new children's ward, new operating room, new out-patients' ward, and committee room, and a new wing for accommodating the nurses. Mr. Alfred and Mr. Leopold Rothschild have given £400 towards the cost of the scheme, and £100 has been given anonymously.

## ORIGINAL PAPERS.

### THE TREATMENT OF SEVERE CASES OF CHRONIC COLITIS.

By J. P. LOCKHART MUMMERY, M.B., B.C.,  
F.R.C.S.,

Hon. Surgeon to King Edward VII. Hospital for Officers; Senior Assistant Surgeon to St. Mark's Hospital for Diseases of the Rectum.

CASES of chronic colitis naturally divide themselves into two distinct classes: (1) Those cases which, if carefully treated by suitable dietary, proper regulation of the bowels, and one or more visits to some suitable spa where proper lavage of the bowel can be carried out, quickly get well, and remain well; and (2), cases in which, in spite of prolonged and careful medical and spa treatment, little, if any, improvement occurs, or the improvement is only temporary, the patient quickly relapsing, and the symptoms, in spite of continued treatment, getting worse. I think everyone who has had any experience in the treatment of chronic colitis will admit that this second type of case not only exists, but forms an unpleasantly large proportion of the whole.

The worst cases of this second class spend their time going from one doctor to another, and in visiting most of the English and Continental spas. Many of them go in for Christian Science, vegetarianism, and other forms of quackery. In fact, they form one of the worst classes of chronic invalids, a nuisance to their doctors, their relatives and themselves. It naturally occurs to one to ask what is the reason that the treatment which seems so effectual in the first type fails so signally in the second? The reason for this is, I think, not far to seek. Chronic colitis is a condition usually diagnosed from the symptoms alone, and I think we shall all admit that the treatment of a disease which is only manifest by its symptoms is always difficult, and owing to the large possibilities of error which must be present in any diagnosis founded only upon symptoms, often unsatisfactory.

During the last few years I have seen a considerable number of the more severe cases of chronic colitis, both in hospital and in private. Most of these cases had previously been treated medically for long periods, and many had also been to spas and had Plombières treatment. For the most part they belonged to the second class of cases that I have mentioned, and medical treatment had failed to give them any permanent relief. All the cases that I have seen have been examined with the sigmoidoscope, and in many an operation has been performed which has enabled me to directly examine the colon and so to ascertain the exact nature of the pathological lesion. I have no hesitation in saying that all cases presenting symptoms of chronic colitis should be most carefully examined with a view to ascertaining the exact nature of the lesion in the colon.

The chief reason for the unsatisfactory results that are often seen in cases of chronic colitis is that the symptoms ascribed to this disease may result from a great many different conditions of widely different characters, and the treatment which is suitable for one case is not suited to others. Our aim should be in all such cases to find out, if possible, the real cause of the symptoms. This is admittedly not always possible, but, on the other hand, it often is.

In a paper read before the Royal Medico-Chirurgical Society, in June, 1907, I first pointed out that in the great majority of cases of chronic colitis a lesion, or lesions, could by suitable means be demonstrated in the colon, that these lesions varied considerably in different cases, and that any treat-

ment which did not take into account the cause of the symptoms is unsound in principle.

The name chronic colitis should be reserved for those cases in which there is a chronic inflammatory condition of the mucous membrane of the colon. These cases can be readily distinguished by examination with the sigmoidoscope, as the sigmoid flexure is practically always involved.

The cases in which there is a definite inflammatory condition of the mucosa, as seen on sigmoidoscope examination, are those which are suitable for treatment by lavage and Plombière's douche. Many of them, in my experience, do well. They form the first class of which I have spoken, and the majority of all cases. On the other hand, there are many cases with identical symptoms in which, on examination with the sigmoidoscope, we find the mucous membrane quite normal, but some other lesion is present. It is this class of case which I propose to consider in detail. In many of these cases there is no inflammation of the mucosa of the bowel, while in others in which there is it is purely secondary to some other lesion. The nature of the lesion varies considerably. An important class is that in which some chronic obstructive lesion exists in the colon, such as adhesions from previous peritonitis or perimetritis. Or a kink or acute angle is present in the pelvic colon as the result of adhesions to the iliac fossa, or in the meso-sigmoid, probably due to old chronic constipation. Another form of lesion is that in which there is a partial volvulus of the sigmoid, or a chronic and recurring intussusception.

We must also bear in mind that cancer of the colon may cause symptoms of chronic colitis, which are indistinguishable from those occurring in the simpler forms. I have seen seven such cases, in several of which the patient had previously undergone treatment for months for a supposed simple chronic colitis.

In another well-marked group of cases we find a chronically inflamed appendix, which, owing to the fact that it has not caused the usual distinctive symptoms, has remained undetected. There is certainly no doubt that a chronically-inflamed appendix may cause symptoms of chronic colitis, though exactly how it does so is not always clear. In some it is due to adhesions which have formed to the pelvic colon, while in others it probably produces symptoms by the constant discharge of septic material into the bowel, in the same way that carious and septic teeth will cause gastric disease.

There is one well-marked group of cases in which all the symptoms of a severe chronic mucous colitis exist, and in which there is no inflammation of the mucosa, but the whole colon is found to be lax and atonic. On examination with the sigmoidoscope, the bowel is seen to be unduly lax, and to have a marked tendency for the upper portions to prolapse into the lower; the walls are thin and semi-transparent; the lumen is dilated, and the normal sacculations much exaggerated. There is generally well-marked ptosis of the transverse colon and of the stomach. In several instances in which I have operated for this condition the centre of the transverse colon has been found in the bottom of the pelvis, lying in front of the upper part of the rectum.

In this type of case the colon is dilated and its walls atonic, but there is no inflammation of the mucosa. It is obvious that it is most important to be able to distinguish this type of case, as treatment by lavage, which involves distension of the already dilated colon, will not only be useless, but will do harm. Such cases are not suitable for Plombière's treatment. It is quite obvious that

these different conditions, although they cause the same symptoms, cannot be classed as one disease.

I cannot believe that the neurotic element, which is so commonly present and about which we hear so much, is other than secondary. I have frequently seen it entirely disappear after the cause of the symptoms has been removed.

One of the chief reasons for the unsatisfactory results that have been obtained in the treatment of many cases of colitis has been inaccurate diagnosis, and treating as a disease what is only a symptom.

The indications for operating in cases of chronic colitis will, of course, depend upon the nature of the lesion present. When there is any evidence of an obstructive lesion, such as adhesions or chronic volvulus, laparotomy is clearly indicated, and affords the only possible method of adequately dealing with the case.

The following is a good instance of the type of case which can only be treated satisfactorily by operation. The patient, a married lady, was recently sent to me by her doctor. For ten years she had been a chronic invalid with mucous colitis. She suffered from a chronic pain in the abdomen, which at times became severe and was always worst on the left side. She had lost weight and always felt ill and depressed. She had fits of weeping and misery on the slightest, and often upon no provocation, and was unable to go about or enjoy life in the ordinary way. She had an earthy complexion, and her appearance when I saw her was typical of toxæmia or auto-intoxication. Her stools contained large quantities of mucus, and often consisted of little else. A curious and unusual symptom was that the presence of anything in the rectum caused an uncontrollable desire to go to stool and much tenesmus. She had been under medical treatment for years, and all the recognised forms of medical treatment had been tried. On examining the bowel with the sigmoidoscope, I found the mucosa quite normal in appearance. In the middle of the sigmoid, however, the bowel was found to be firmly fixed and angulated, apparently by adhesions. The uterus was also found to be markedly retroflexed. It seemed probable that the tenesmus from which she suffered was due to the condition of the uterus, and a gynaecologist who saw her with me confirmed this view.

I opened the abdomen, and found a number of firm adhesions bearing down and kinking the middle of the sigmoid flexure; these were divided, and the wound left in the peritoneum sewn up. The uterus was also drawn forward and anchored to the abdominal wall so as to correct the position.

The patient made a good recovery, and all her symptoms have now completely disappeared. When I last saw her some months after the operation she had put on weight, her complexion was good, she no longer had any mucus in the stools, and she told me that she never remembered feeling so well and fit.

Though most of the cases of true colitis (that is to say, when a chronic inflammation of the mucosa of the colon is found) get well, as the result of medical treatment and lavage, there are nevertheless a certain number which either fail to get entirely well, or suffer from frequent relapses. These cases are, I believe, best treated by appendicostomy. This enables the patient to keep the colon efficiently washed out daily with the minimum of inconvenience, and the symptoms quietly clear up.

The most difficult cases to treat are perhaps those in which there is a general atony of the bowel combined with ptosis of the colon. Stitching up the

colon is quite useless, as it is unreasonable to expect any stitches to permanently hold up the stomach and transverse colon when the natural supports have not been sufficient to do so. It is impossible to directly deal with the condition, but I have had very satisfactory results in such cases from appendicostomy. The object of the operation in such cases is to prevent the stagnation of the faecal contents of the colon, which is the chief cause of trouble, and at the same time by the introduction of suitable peristaltic stimulants to improve and restore the muscular tone of the bowel wall.

The following well illustrates this type of case:—Mrs. B., æt 32, a married lady, was sent to me by her doctor, suffering from severe chronic colitis. There was a history dating back twelve years, though the symptoms had only been really severe for the last four years. She always felt ill, and had a chronic aching pain in the left side of the abdomen. She was always very constipated, and had to take large doses of aperients, and this often without success. The stools contained mucus, and often large casts several feet in length. She had been treated for long periods by the usual remedies, and had on different occasions consulted several well-known physicians, but without obtaining any relief from her symptoms.

Examination showed an atonic condition of the bowel, and the mucosa showed chronic inflammatory changes. There was also well-marked ptosis of the transverse colon. I operated, and on opening the abdomen, found the colon much dilated and thin. There was also considerable enteroptosis. Appendicostomy was performed, as the only alternative seemed to be removal of the colon. The colon was subsequently irrigated daily with warm water (at first in small quantities) to which a teaspoonful of ox-bile was added. She rapidly improved in health, and learned to wash out the bowel for herself. The mucus entirely disappeared from the stools, her health improved, and the bowels acted without any aperient being used. During the next six months she put on 2 stone in weight, and when I last heard from her about nine months after the operation she was quite well, and although, on my advice, still washing out the bowel, was quite free from any of her old symptoms.

Appendicostomy is an operation followed by excellent results in many of those cases, but it is not a panacea for all cases of so-called chronic colitis, any more than is lavage. It should only be performed in suitable cases, and that can only be done if we first ascertain the cause of the symptoms. I have seen cases in which appendicostomy has failed even to relieve the symptoms, because there was some obstruction or other lesion which had not been detected. I do not wish it to be thought that I am advocating operation in all cases where there are symptoms of chronic colitis. I think operation should only be resorted to after a careful trial has been given to medical treatment. But the important thing is to ascertain the cause of the symptoms by a careful examination, aided, whenever possible, by the use of the sigmoidoscope, as it is useless treating a case by medical measures where there is an obstructive lesion in the colon, or a chronically-inflamed and thickened appendix. And, in any case, it is not satisfactory to institute treatment without knowing the cause of the symptoms.

In order to meet an overdraft at the bank, and to prevent the Imperial Cancer Research Fund from drawing on its capital, the honorary treasurer has received from the Duke of Bedford another donation of £1,000.

## A NEW PROCEDURE FOR THE TREATMENT OF DISEASES OF THE NOSE.

By EMIL SPRENGER, M.D.,  
Of Stettin.

[SPECIALLY REPORTED FOR THIS JOURNAL.]

ANY one organ of our bodies can only remain normal and healthy when it really exercises the function prescribed for it in the animal economy. In doing so it is subject to a number of physiological irritations; to which it must react if pathological changes are not to follow.

In what then does the function of the mucous membrane of the nose consist, and to what physiological stimuli is it subjected? In this I do not consider the nose as an organ of smell, as this function does not enter into the question.

The work that has to be performed by the nasal mucous membrane consists in the following:—

1. It has to keep back the particles of dust of the atmosphere, etc.

2. It has to saturate the air inspired with as much moisture as possible; it is enabled to do this through its great vascularity and extent of surface, besides this the turbinated bones retain a portion of the moisture of the expired air to give it back to that which is being inspired.

3. It has to warm the air inspired, and Aschenbrodt and Kaiser determined by a series of experiments that the air inspired was warmed to about 30 C., the warmth of the expired air is reckoned at about 36 C., it is therefore almost that of the cavities of the body.

This is what the nasal mucous membrane has to do; in doing this it is subject to the following stimuli:—

1. To the irritation caused by the particles of air streaming through the nose. (Mechanical irritation.) Here the following has to be borne in mind: the degree of this irritation is not always identical, there are natural rest pauses, one, that which comes in between the two phases of respiration; moreover, expiration does not always begin as soon as the act of inspiration is completed. Finally, at the commencement of inspiration and at the end of expiration, there is even, if only for a short moment, a rest. There is a true streaming through the air only at the heights of both inspiration and expiration; at the commencement of inspiration there is a moment when air only passes through the choanæ into the naso-pharyngeal space, and at the end of this, when only air from outside enters the nasal passages, these three factors bring about a period of physiological rest, in which the mucous membrane can rest from its labour.

2. The atmospheric pressure on the mucous membrane is a changing one, for Donders has calculated the pressure of inspiration to be 7 to 8 mm. of water and that of expiration at 9 to 10 mm. This changing pressure is not a matter of indifference to the vessels of the nasal mucous membrane, it is a powerful stimulant. (Mechanical irritation.)

3. It is subject to the stimulus from air that is cold compared with that of the internal air passages; a rather powerful stimulation by cold is therefore in action under some conditions. (Thermic stimulation.)

4. I only point out the different chemical qualities of expired air as compared with that which is inspired. Expired air is richer in carbonic acid, it contains a little ammonia, and carburetted hydrogen. It is therefore not excluded that a chemical stimulation may not take place from the rhythmical succession of columns of air of such

different compositions. (Chemical stimulation.) As the nasal mucous membrane performs its functions therefore it is acted upon freely by mechanical, thermic and chemical stimuli.

How do these relations become changed when the nasal mucous membrane is in a pathological condition? I have first of all simple chronic catarrh in my mind, in which hypertrophies and hyperplasias have taken place. In consequence of the mucous surface being diseased a mixed nasorostral breathing comes into action, or even a purely oral breathing; but in the latter case the patient must under certain conditions, such as in eating and drinking, draw air through his nasal passages by forcible inspiration, and as well as he is able. We have not here then a period of changing work and rest, but an organ placed completely out of work and then subjected to the forced passage of air. We do not have therefore a periodical change between work and rest, but a complete period of inactivity on the part of the nose, followed by a forcible driving of air through the passages. In the latter case we do not get a lower pressure of 7 to 8 mm. of water within the nose, but one considerably greater, as the external air will not enter as easily as under normal conditions. The pressure within the nose diminished by the pathological condition exerts a powerful suction action, and leads to passive hyperæmia, and this on its part, when present during every or nearly every inspiration will lead to new hypertrophies, or make those worse that are already present. Moreover, this pressure diminished pathologically, will not be equable over the whole of the nasal interior, but be especially noticeable at the diseased parts.

By the lesser or greater out-of-work condition of the nose also, the stimulation required for the health of the nose, will be correspondingly in abeyance.

First of all the mechanical stimulation of the air inclusive of its constituent parts.

Further, the nasal mucous membrane will not receive the stimulation of the cold of the external air. As now as much cold air cannot stream in as under normal conditions, a higher temperature will rule within the nasal interior than in health. This higher temperature combined with diminished pressure will lead to arterial hyperæmia, and this associated with the venous stasis already present will make the condition distinctly worse.

As less air passes through the nose, less carbonic acid and ammonia will come in contact with it.

And thus arises a *circulus vitiosus*; if the nasal mucous membrane becomes chronically affected from any cause, the nose does not act as under normal conditions, it does not receive the physiological stimulus necessary to health, it changes still more into a condition of disease, for that reason again it does less work, etc.

If we could cut through this *circulus vitiosus* at a stroke, that is if we could make the nose perform its functions normally, and cause it to get its normal physiological stimulus, we should at once mend matters. But that we can do: a typical example is the adenoid growths of the nasopharyngeal space. When these are present the nose is acting under conditions similar to those I have described as existing with chronic catarrh; for adenoid vegetations almost always lead to chronic nasal catarrh. When therefore we remove the adenoid vegetations, and in doing so restore to the nose the possibility of a normal function with a susceptibility to normal physiological stimulation, the nasal mucous membrane is frequently unrecognisable in the course of a few days.

For the nasal mucous membrane, therefore, physiological function and physiological rest are necessary. But this is so only as regards the healthy membrane; so soon as it becomes diseased, the stimuli that are required in the normal condition, become too powerful for it, and the normal pauses for rest are no longer sufficient. If, therefore, we would bring about an improvement in the diseased part we must provide for longer pauses for rest, that is we must bring about a temporary state of rest, and for this the mechanical, thermic and chemical stimuli must be kept back as much as possible.

It was thoughts like these that kept me busy thinking for some time, and which at last led to the construction of small spongy rubber balls to be retained just within the nasal entrance, which I will describe more closely.

They are small clear yellow balls or pellets of porous india rubber, the so-called "sponge rubber," they are about 12 mm. in diameter, they are furnished with a stalk for the purposes of easy handling and cleanliness. Especially delicate individuals could make use of a specially constructed pair of forceps for insertion and removal. (a) These little balls are inserted into the lower part of the nostril and retained there for half to three-quarters of an hour several times a day. Nothing but the stalk will be visible. They are of an uncommon softness and are practically of no inconvenience to the wearer, they fill up the nostril, however, thanks to their great elasticity. I generally only let one nostril be closed, and then make the patient breathe calmly but deeply through both. If both nostrils were closed, inspiration through the diseased nostril would be made too difficult. If too difficult when only one of the balls is inserted I direct the patient to draw in the breath through the mouth.

What is experienced now after insertion of the pellets? First of all a feeling of fullness is felt in the nostril, and also one of increased warmth. Very soon, however, in two or three minutes perhaps, a feeling of great relief comes on. The feeling of dryness that is often so troublesome disappears as the increased blood supply increases the secretory action of the glands. The impulse to drive air from the back through the choanæ outwards also disappears, the nose becomes free so that it can easily be blown out. In a word, the wearing of the pellet is agreeable, as I have been assured by all that have worn them. When the pellet is removed the nostril that has carried it is free, just as after an application of a weak solution of cocaine, and agreeably moist. It can now be easily cleansed as already mentioned. This condition of relief often lasts from one to two hours; and when it passes off can easily be brought about again by the same means which are thoroughly harmless and agreeable. I have often made the observation that when a person has once worn the pellets he wishes to wear them again. If the nose is examined rhinoscopically after withdrawal of the pellets a distinct diminution of the swelling will be found with slight paleness of the mucous surface.

If the pellets are worn regularly according to directions for several months a marked improvement, or even complete recovery, from the diseased condition takes place.

How then do the pellets act? Stated shortly: through the temporary venous stasis, associated with arterial hyperæmia acting under conditions of rest on the part of the nose, that is removal of physiological stimuli.

(a) Procurable from the firm "Unitas," Scotland, Falkenhead-Strasse, also the forceps.

The chest dilates on inspiration, and the air will stream through the anterior nasal openings and choanæ, to bring that in the chest to an equilibrium, but it cannot follow so quickly, as the tortuous channels of the india rubber offer resistance; consequently, the air in the interior of the nose becomes rarefied, the rarefaction being considerably greater than the normal of 7 to 8 mm. of water. A passive hyperæmia results from this (through suction). But there is a simultaneous rise of temperature within the nose, as the colder external air can only pass through the nostril at a moderate rate of speed. The heightened temperature again leads to arterial hyperæmia, which as is well known accelerates absorption in an uncommon degree. With this all the mechanical, thermic chemical irritants disappear, in consequence of the obstruction caused by the wearing of the pellets.

In what then lies the difference between the condition brought about by the pellets and that of chronic catarrh? First of all in one important particular. In chronic catarrh the condition is permanent, whilst from the pellets a changed condition is brought about from time to time only. By the congestive treatment, the diseased organ or the inflamed part is only subjected to venous stasis and arterial hyperæmia at intervals. Besides the conditions differ in other important details:—

1. By insertion of the pellets a heightened temperature is brought about in the interior of the nose, as they close the interior from the outer world fairly well, whilst in chronic catarrh there is free and open communication; the raised temperature, as is known, leads to the arterial hyperæmia.

2. The pellets act as a filter, and keep back those constituents of the air that often act as irritants. In chronic catarrh on the other hand, they often get into the nose even if in diminished quantities.

3. There is also a difference in the hindrance to respiration being at the entrance to the nasal passages and not in the interior of the nose, as in chronic catarrh. When the pellets are inserted there is everywhere within the nose an equally diminished pressure, and an equally distributed warmth, whilst in chronic catarrh the pressure is not equable and the heat is not equably distributed.

In what diseases can the pellets be made use of with advantage?

1. In simple chronic catarrh, especially in those forms that are accompanied by dryness, which is shown by the glistening look of the mucous membrane as viewed through the nasal speculum. But the pellets give relief also in cases in which there are polypi, making the passage free for the moment, although, of course, they have no permanent influence on the growth. They are very useful finally, in the cases in which there is an abnormal tendency to engorgement of the erectile tissues. For those severe cases with a good deal of hyperplasia surgical treatment or caustic must be resorted to.

2. In chronic catarrh of the naso-pharyngeal space. Here the action is in no need of explanation. Here the posterior wall of the fauces has to stand the whole of the inroad of the particles of air and dust; a period of rest can only be of advantage in recovery from the condition.

3. In ozæna. Here the good effect can be explained by the increased blood supply bringing about better nourishment of the atrophied mucous membrane; the increased glandular activity moreover plays a part, the scabs fall off readily, an effect similar to that from applying tampons of

lint (Gottstein's tamponade) is produced, the use of the pellets is also more simple, more agreeable, and the action is more certain, as patients are not always successful in applying the tampon over the parts most in need of them. When tampons are made use of it is only in a few spots that an increased secretion is excited, and those not always the worst, whilst with the pellets an increase of secretion is set up over the whole surface. Finally, the pellets act in such a way that the widened interior of the nose is corrected by the artificial narrowing of the nasal orifice; it is the same idea that led to the injection of paraffin under the mucous membrane. In quite a large number of cases of ozæna, I have been satisfied that striking improvement has taken place after the use of the pellets. The improvement makes itself known subjectively by the patient getting rid of the scabs more easily, by the nasal interior being almost always free from them, and by the lessened fluid discharge. When the pellets are used patients at any rate feel better than after any other kind of treatment.

4. The pellets are eminently suited for employment for after treatment after surgical operations on the nose. For one thing the scabs fall away more easily, and it is also of value to bring the nose under better conditions as regards nourishment after operations, otherwise one is never certain about recurrences.

5. In hay fever I have no experience of my own in regard to treatment by the pellets. Theoretically their use would come into question, firstly on account of their filtering property; there is ample provision for keeping the excitors of hay fever back in the narrow meshes of the spongy rubber. On the other hand it is conceivable that if the pellets were worn in the free intervals, such a change would take place in the mucous membrane, that at the time of an attack it would be in a position to resist the influence of the poison.

6. They might prevent the so extraordinarily frequent sucking in of the alæ nasi, as by their elasticity they would prevent their clinging to the septum. In such a case a wider meshed india-rubber would have to be used, so that sufficient air could enter. The pellets would then enter into rivalry with the rubber ovals of Schmidthuisen, the wireloops of Feldbausch, and the lint and boracic ointment pellets of Heermann.

7. Whether they will prove a substitute for the suction mask of Kuhn the future will have to show. The fundamental thought is the same: more difficult nasal inspiration with freer oral expiration. It is possible that they may be used with advantage in the diseases mentioned by Kuhn (pulmonary tuberculosis, asthma, etc.) vide Dr. Ernst Kuhn, *Deutsche med. Wochens.*, 1906, No. 37, and *Münch. med. Wochens.*, 1907, No. 16.

8. Finally, the pellets may be used with advantage when working in a dust-laden atmosphere; by reason of their filtering property they cannot fail to be of value.

The range of possible employment of the pellets is, therefore, very great, and as they are perfectly harmless, and agreeable to wear, they are in my opinion well worthy of a trial.

## SLEEPING SICKNESS: A STUDY OF THE TSETSE FLY. (a)

BY CAPT. E. D. WILSON GREIG, M.B., C.M.,  
Indian Medical Service.

THE author remarked that the study of tsetse flies and the diseases disseminated by them is not only of

(a) Abstract of a lengthy and interesting Paper read before the Indian Medical Congress, February, 1909.

scientific interest but of great practical importance. This becomes apparent when it is remembered that several hundred thousand inhabitants of Uganda alone have lost their lives from sleeping sickness, which is a tsetse fly disease. In Africa sleeping sickness has become one of the greatest scourges of recent times. As there is constant communication between India and Africa, it seems desirable for us to carefully consider the facts already discovered by the scientific investigation of this disease and the agent which spreads it; it is especially appropriate to deal with this subject in this Congress at Bombay, which is the great portal of India.

In April, 1903, I was deputed by the Government of India to proceed to Uganda to join the Sleeping Sickness Commission of the Royal Society. This Commission was very fortunate in having at its head so distinguished an investigator as Colonel (now Sir David) Bruce, F.R.S., to solve the very difficult problems which presented themselves, namely, the causation of this mysterious disease and how it was spread from the sick to the healthy. These questions, as this paper will show, were conclusively answered by the work of the Commission. After Colonel Bruce left for England, I carried on the work of the Commission with Lieut. A. C. H. Grey, R.A.M.C., until the end of 1904, and then proceeded from Uganda along the course of the Nile to Egypt, investigating the distribution of the tsetse fly and sleeping sickness.

The results of the Commission were summed up as follows:—

1. That sleeping sickness is caused by the entrance into the blood and cerebro-spinal fluid of a species of trypanosome.
2. That this species is probably that discovered by Forde and described by Dutton from the West Coast of Africa, and called by him *trypanosoma gambiense*.
3. That the so-called cases of trypanosoma fever, described from the West Coast, may be, and probably are, cases of sleeping sickness in the earliest stages.
4. That monkeys are susceptible to sleeping sickness and show the same symptoms, and run the same course, whether the trypanosomes injected are derived from cases of so-called trypanosome fever or from the cerebro-spinal fluid of cases of sleeping sickness.
5. That dogs and rats are susceptible, but that guinea pigs, donkeys, oxen, goats and sheep, up to the present, have shown themselves refractory.
6. That the trypanosomes are transmitted from the sick to the healthy by a species of tsetse fly—"glossina palpalis" and by it alone.
7. That the distribution of sleeping sickness and *glossina palpalis* correspond.
8. That sleeping sickness is, in short, a human tsetse fly disease.

**THE DEADLY GLOSSINA PALPALIS.**—The fly with which we are more particularly concerned in connection with disease in man is the *glossina palpalis*, as it is this fly which has been demonstrated to be the carrier of *trigambiense*, the causal agent of human trypanosomiasis (sleeping sickness), as well as three varieties of animal trypanosomiasis—"jinga cattle disease," "mule disease of Uganda," and the "Abyssinian fly disease." There is some evidence to show that other varieties of tsetse fly, e.g., *glossina fusca*, may convey the parasite of sleeping sickness as well as *glossina palpalis*. This important problem will no doubt be studied by the New Sleeping Sickness Commission in Uganda. When the *glossina* attacks man or animals its flight is direct and makes a slight buzzing sound. It frequently strikes men on the back of the neck, which is generally naked. It gives a sharp prick with its proboscis; this is frequently the first indication of the presence of the fly as it alights very gently. The bite does not leave much irritation, not so much as a mosquito sting. They are generally most active during the hot part of the day, becoming drowsy towards evening when they may be caught on the leaves of trees. Ensor, however, states "that in the Bahr-el ghazal province of the Soudan the tsetse fly, *glossina palpalis*, is most active from about sun-

rise to 10 a.m., and from 4 p.m. to sunset." They are said, however, to be active on moonlight nights—an important fact, as it is customary to take animals through "fly areas" at night to avoid the bites of the fly.

The tsetse fly, unlike other diptera, has a remarkable distaste for ordure. For this reason it is rarely found in the neighbourhood of towns or habitations.

The mean life of the female *glossina* is about three months, and a series of eight to ten pregnancies represent the fecundity of the insect; as a single larva only is laid each time, it will be seen that the tsetse fly is not very prolific.

Nagana, or the classical tsetse fly disease of animals, renders thousands of square miles of Africa uninhabitable. No horses, cattle or dogs can venture, even for a day, into the so-called "fly country." At one time it was thought that the tsetse fly killed the animals by injecting a poison into them in the same way as a snake kills its prey, until the investigations of Bruce in 1895 showed for the first time that the disease is caused by a minute blood parasite (*trypanosoma*), and that this parasite was conveyed from the sick to healthy animals by the bite of a variety of tsetse fly (*glossina morsitans*). He further showed that the wild game harboured the parasite without showing any signs of disease. They were immune or "salted" to this disease, and acted as "reservoirs" of the parasite; as soon as they were killed off or driven away, the tsetse fly disease disappeared, as occurred in the great Rinderpest epidemic amongst the buffaloes in 1906. Further the disappearance of the big game deprived the tsetse fly of a source of food, and so the numbers of tsetse flies became reduced.

**SLEEPING SICKNESS.**—The sleeping sickness has been known clinically on the West Coast of Africa for over a hundred years, but its cause and mode of spread remained a mystery until 1903. It extends along the Coast and up the river valleys from the 15° N. to 15° S. latitude. With the opening up of Central Africa it has extended from the Congo eastward into Uganda to the north as far as Gondokoro on the Nile, and south to Lake Tanganika. It is now one of the most serious scourges of modern times. In Uganda the disease was probably introduced into this area from the Congo by the remains of Emin Pasha's Soudanese troops and followers, some 10,000 in number.

The incubation period of sleeping sickness, that is, the interval between the bite of the infected tsetse fly and the appearance of enlargement of the cervical glands in the neighbourhood, is, according to Martin and Lebœuf, about ten days. In the early stage of the disease, the only definite clinical feature is a distinct enlargement of the lymphatic glands, particularly the cervical. This phase may be called the stage of polyadenitis, and is accompanied by an increase of the lymphocytes in the blood. On examination of the juice of these enlarged glands we were able to demonstrate the constant presence of trypanosomes in them; thus the specific nature of the glandular enlargement was established, and, in addition, a ready method of detecting the parasite in the tissues of man was discovered.

Sooner or later, the stage of polyadenitis is complicated by signs and symptoms indicating involvement of the central nervous system. It was to this last stage of the disease that the name sleeping sickness was given. It is produced by the trypanosome gaining an entrance into the cerebro-spinal system, and producing there the characteristic pathological changes which were first described by Mott. So far as present experience goes, when this stage is reached, the disease is invariably fatal. A number of cases die during the stage of enlargement of glands from intercurrent affections, e.g., pneumonia, etc.

The disease attacks both black and white, male and female, young and old without discrimination.

The patient acquires a curious sleepy or drowsy expression, hence the name of the disease. If the patient be spoken to at this stage, he answers in a hesitating manner, and his lips and tongue show fine tremors. As a rule he is greatly wasted, his gait is

uncertain, and finally, he becomes completely bed-ridden. This last stage lasts about three to six months on an average. In some cases the patient develops symptoms of mental derangement, and may become maniacal. The temperature keeps above normal during this stage of the malady, but about a week or two before death it becomes subnormal and remains so.

**THE PARASITE.**—After discussing the investigations by which it was established that *glossina palpalis* conveys the *trypanosoma gambiense*, the causal agent of sleeping sickness, from the sick to the healthy, Captain Greig said: We proved that up to 48 hours, but not longer after feeding on a patient suffering from sleeping sickness the tsetse fly (*glossina palpalis*) was capable of infecting a healthy monkey.

As a result of examination, it became evident that 50 to 75 per cent. of the population of the "Infected Fly Areas" in Uganda harboured the parasite of sleeping sickness, and they were carrying on their ordinary work showing few or no signs of disease, glandular enlargement being the only constant feature; these persons take the place of the wild game in the case of nagana and act as "reservoirs" or "carriers" of the parasites. It is this class of case which is especially liable to infect "clean" fly belts.

The examination of the population in a "Non-infected or Fly-free Area" showed that practically none of the inhabitants harboured the parasite, and such as did had a history of exposure in an "Infected Fly Area."

In 1903 the Sleeping Sickness Commission of the Royal Society in Uganda experimentally proved that the extremely fatal disease, sleeping sickness, was caused by a trypanosome, which was *trigambiense*. These trypanosomes are all very minute, and have a somewhat elongated eel-like form, their average length is one-thousandth of an inch. They are simple protoplasmic animals, consisting of one single nucleated corpuscle. They have no mouth; nutrition being effected by the imbibition of soluble nutrient material. When living they move rapidly about in the fluids of the body, being propelled by the contractions of a fin-like structure. They reproduce by a simple division; this is, so far as is known, the only method of reproduction of trypanosomes.

In studying the trypanosomes in the tsetse fly, the first question to answer was, whether the trypanosome underwent any development cycle in the tsetse fly similar to the life cycle of the malarial parasite in the mosquito. Minchin went to Uganda to study the life cycle of *trypanosoma gambiense* in the local tsetse fly, *glossina palpalis*. His investigations on this point have yielded entirely negative conclusions. He never found any signs of *trypanosoma gambiense* later than the fourth day after infection.

**METHODS OF PREVENTION.**—Dealing with methods of fighting the disease the paper continued that operations directed against the fly were on the lines of:—

(1) Destruction of the pupæ of the fly—(a) By clearing of undergrowth—particularly near towns, encampments, fords, etc., in fact, wherever human beings are brought together in numbers. The clearing is best effected by burning. The heat generated by the fire, and the exposure of the area to the full effects of the sun's rays by removing the shady undergrowth, render the district unsuitable for the fly by raising the temperature above the point favourable to the development of the nymphæ. So in time the fly will die out of these "cleared areas." The fly does not exist apparently in hot, dry countries, e.g., Egypt and India, probably owing to the fact that the nymphæ cannot develop under conditions found in these countries.

(b) Destruction of the food-stuff of the fly.—The fly as we have seen lives almost exclusively on blood, hence if deprived of this source of food supply a diminution of their numbers in the first instance, and ultimately a complete eradication might be expected. If the views of Koch be correct, the problem is further simplified, because as we have seen that he is of opinion

that the crocodile is the chief source of supply of blood for the tsetse fly, and he has accordingly recommended the wholesale destruction of these animals.

A fresh Commission under Sir David Bruce, F.R.S., is working in Uganda, and one of the problems which will engage the attention of this Commission is the proposition that the blood of the crocodile is the main source of food supply of the tsetse fly. The Report of this Commission will be awaited with interest.

(2) Destruction of the fly by other animals which will prey on it.—This might possibly be a practical line of attack. Certain kinds of fish have been employed to destroy the larvæ of mosquitoes. The cultivation of some plant might be found whose odour would be obnoxious to the fly.

As the investigations progress, other lines of attack on the fly will probably suggest themselves.

As to operations directed against the parasite which the fly transmits, it is obvious if we can devise means for preventing the fly from becoming infected by the *trypanosoma gambiense* it will cease to be a disseminator of sleeping sickness. In the case of animals infected by trypanosomes, the problem is comparatively simple, and consists in the slaughter of such animals as are found harbouring the parasite, and in this way the disease is stamped out gradually. In the case of man means have to be discovered by which it will be possible to completely destroy all the trypanosomes without damaging seriously the host. This problem has not yet been solved, but it is engaging the serious attention of a number of investigators. The whole subject of the treatment of trypanosomiasis by drugs is being considered by a Committee of the Royal Society. The Report of this Committee will be looked forward to with much interest. Until a means of destroying the trypanosomes in the vertebrate host has been found it is necessary for us to fall back on measures which aim at preventing the association of the harbourer of the parasite and the tsetse fly.

At the present time the authorities are fully alive to the importance of selecting sites for stations in a fly-free area. Previous to the work of the Commission in Uganda, what appeared to be a very favourable site for the Administrative Capital of Uganda, Entebbe, was selected. It was close to the Lake. During the researches of the Commission, the Botanic Gardens, Entebbe, furnished us with many specimens of *glossina palpalis*. On account of the presence of the tsetse fly the question of the removal of the station from Entebbe to a "fly-free area" was considered. However, extensive clearing operations were undertaken with the object of eradicating the tsetse fly from Entebbe. In selecting sites for stations in the future in sleeping sickness districts the question of the presence of tsetse flies will always require to receive most careful attention.

As regards personal protection, those going to countries, where tsetse flies and sleeping sickness occur, should acquaint themselves with the knowledge, which recent scientific investigation has placed in their hands, and rigorously follow out the indications. Before the nature and mode of spread of sleeping sickness had been accurately determined, persons living, even for a day, in districts in which the disease occurred, ran great risks. Now with suitable precautions these risks can be obviated, and this is the direct result of the scientific investigation.

## CLINICAL RECORDS.

### THREE OPERATIONS FOR BREAST CANCER—WITH COMMENTS.

By S. J. ROSS, M.D. VICT.,

Surgeon to Out-Patients, Bedford County Hospital.

THE first patient was a stout woman, æt. 55, who had a scirrhus carcinoma of the left breast, with implication of the axillary glands. In August, 1904, I removed her breast, together with both pectoral muscles, and cleared out her left axilla.

No drainage was used. The wound healed by first intention. In May, 1907, she had an attack of dyspnoea; in June dyspnoea was constant. The scar of the wound was perfectly sound; there was no local recurrence of the disease, but she died from extension of the disease to the bronchial glands.

The second case was that of a spare woman, æt. 62, who had a scirrhus tumour in her right breast. No axillary glands could be felt. I removed her breast, together with the pectoralis major. Upon opening her right axilla, several hard glands were removed which proved to be malignant. She died four years after the operation from involvement of the pleura and lungs, having a large hæmorrhagic effusion into her right pleura. There was no local recurrence in this case. No drainage was used, and the wound healed by first intention.

The third case was that of a woman, æt. 50, who had a very large scirrhus of the left breast, with a mass of axillary glands. I removed her breast, together with both pectoral muscles, and cleared out her axilla. No drainage was employed. The wound healed by first intention. I saw her a month ago, five months after the operation, and the wound remains sound.

*Comments.*—I think that it is most important in these cases that no drainage be adopted, but that the wound heals by first intention. We have often seen recurrence take place at a part of the wound where suppuration has taken place, or at the site where a drainage tube has been employed.

Secondly, we must realise that it is absolutely impossible in these cases, by examination of the mammary tumour, to divine how far cancer has spread to internal organs.

All these patients were cured, so far as the local affection was concerned, and yet two of them have died from spread to internal organs.

How unsafe it is to conjecture that, because a patient has been free from recurrence for three years, the patient is cured. The moral of these cases is that every patient who has a mammary tumour should have the tumour removed as soon as it is discovered. Who dare prophecy that a young patient who has an adenoma of the breast will not develop cancer in later years? In every case of cancer of the breast the axilla should be thoroughly explored, as often we are unable to discover glands which are present until we have exposed them by the knife. Some surgeons, in cases of small tumours of cancerous nature, are contented with cleaning the pectoralis major by removing the pectoralis fascia; but anyone who has studied the work of Stiles will understand how ineffectual such a method is.

The removal of the pectoral muscles does not materially increase the shock of the operation, nor does it interfere with the usefulness of the limb. In many cases we find glands near the coracoid process, which can only be effectually dealt with by removing the pectoralis minor.

In every case of cancer of the breast, however small and apparently localised the growth, we should explore the axilla. If this were adopted as a routine practice, we should have less of "recurrence" in the axillary glands.

## OPERATING THEATRES.

### GREAT NORTHERN HOSPITAL.

**RUPTURED ECTOPIC GESTATION.**—MR. ARTHUR EDMUNDS operated on a married woman, æt. 35, who had been admitted complaining of pain and tenderness in the hypogastrium. The pain commenced suddenly 48 hours before, whilst the patient was engaged in her household duties. It was only moderate in

severity, its intensity seeming most matured in the right iliac fossa. She was slightly sick on one or two occasions; she had had one child three years before, and the last period had come on three weeks before the onset of the pain, and presented nothing abnormal. There had been no symptoms referable to the pelvic organs, and no discharge of blood. On admission she appeared well nourished, slightly pale, but not extremely so; her temperature was 102, pulse 140. On examination, the abdominal wall was slightly rigid, but not very definitely so, and, indeed, the sensation obtained was more one of distension than of actual rigidity. No free fluid was demonstrated. Per vaginam, there was tenderness on pressing the uterus upwards, but no tumour could be made out.

The diagnosis in this case, Mr. Edmunds said, was obviously difficult, but it was pretty clear that something acute was happening in the lower part of the patient's abdomen, and the symptoms suggested an acute inflammation of either the vermiform appendix or the Fallopian tube; and the general condition of the patient, the fact that she had a clean tongue and no symptoms of intestinal disturbance, the absence of definite rigidity, suggested that it was tubal rather than an appendicular inflammation. The symptoms, however, were too indefinite for a conclusive diagnosis to be made. In such cases, where the patient is in her own home, it may be justifiable, he thought, to wait for definite symptoms which would clear up the diagnosis, but, even under these conditions, the surgeon can never be free from anxiety, as there are many cases of appendicitis in which the symptoms are as vague, although an operation reveals that the patient's condition has been one of grievous danger, and it is, therefore, advisable in all such cases for the patient's safety that she should be kept under the closest observation, and arrangements made for a surgical operation at any moment.

In the present case, as the patient was in hospital, and everything ready for an operation, the abdomen was opened 24 hours after admission. On incising the peritoneum, the diagnosis was made manifest, the abdomen was full of blood and clots, and on passing the hand down into the pelvis the ruptured sac could be felt in the left Fallopian tube, the other pelvic organs being normal.

It must be remembered, Mr. Edmunds remarked, that in these cases the hæmorrhage is going on slowly, even when the patient is blanched, obviously suffering from hæmorrhage. Cases undoubtedly occur in which a large vessel is opened, and the patient dies before any treatment can be undertaken; but in the majority of cases the hæmorrhage is not of such severity, so that, although no time should be lost in operating or during the operation, there is no need for any undue haste. This is specially important, inasmuch as the tissues around an ectopic gestation are extremely soft and pliable, and require great gentleness in handling. There is little difficulty in drawing up the right ovary and tube into the incision made for the removal of the appendix, but a similar amount of traction on a Fallopian tube which is the seat of a ruptured ectopic gestation would lead to further laceration and increased hæmorrhage. Accordingly, in the present case the blood was carefully evacuated, and washed out with large quantities of salt solution; the wound was widely retracted, and the intestines packed off with a sterilised towel, so that a good view of the pelvic organs could be obtained. The sac was then excised, but, in spite of all this care, another small vessel was torn across, probably in the round ligament, and required another ligature. This, however, was quite simple, as a good exposure of the parts had been obtained.

The importance of deliberation in these operations, Mr. Edmunds pointed out, cannot be too strongly insisted upon, as this not only shortens the time of the operation, but enables the operator to be certain that complete hæmostasis has been secured. Some fresh salt solution was then poured into the abdomen, and the abdominal wound closed. The patient's condition after the operation was quite good, and she is now making a satisfactory recovery. The ruptured sac was about an inch in diameter.

## CORRESPONDENCE.

### FROM OUR SPECIAL CORRESPONDENTS ABROAD.

#### FRANCE.

Paris, August 22nd, 1909.

##### LUMBAR PUNCTURE.

In all cases where cerebro-spinal meningitis is suspected, lumbar puncture should be practised. Evacuation of a cloudy liquid justifies the employment of intra-rachidian injections of specific serum without waiting for bacteriological examination.

The *modus operandi* of the puncture is as simple as the tapping for ascites or thoracentesis, and no practitioner should hesitate to practise it when indicated.

The arachnoidian sac, void of the medulla, and containing only the nerves of the cauda equina, extends, in the normal condition, from the second lumbar vertebra to the second vertebra of the sacrum; it is between these two extremes that the puncture may be made.

However, in order to avoid with certainty wounding the cord, especially in children where it descends rather low, it is preferable not to tap between the second and third vertebra, says M. Desfosses, who has published a very complete description of the operation.

M. Tuffier prefers the space comprised between the fourth and fifth lumbar vertebrae as being more easily mapped out, and the majority of surgeons have accepted this view.

A horizontal line drawn between the two iliac crests cuts the spinal column exactly at the level of the apophysis of the fourth vertebra.

The index of the left hand of the operator is placed over this apophysis, and follows its crest from above downwards to its internal angle; right beneath is the fourth lumbar space, the point of election.

A needle penetrating horizontally at this point, from before backwards, meets with, in succession, the skin, cellular tissue, lumbar aponeurosis, sacro-lumbar muscles, yellow ligaments, and the coverings of the cord.

The needle should be sufficiently long to pass through the several layers above-mentioned, while it should be strong enough not to bend or break if it encountered a bone, and these qualities are found in a platinum instrument.

It is frequently useful, says Dr. Desfosses, to adapt to the needle before operating an india-rubber tube to moderate and regulate the flow of the rachidian liquid.

As to the position of the patient, surgeons prefer the sitting posture, while physicians choose rather the lateral decubitus.

In the former case the patient sits on the edge of the bed, the legs slightly separated, the arms thrown forward, and the back rounded as much as possible. In the lateral position the head is slightly raised on a pillow, and the legs drawn up as much as possible, so as to obtain the maximum separation of the vertebrae.

When all aseptic precautions are taken, the back of the patient and the hands of the attendant well washed and rubbed with alcohol or ether, the index of the operator is placed on the spinous apophysis, and the needle is inserted right against the outer edge of the finger, and pushed with gentleness but firmness horizontally and slightly inwards.

A certain resistance is felt at the moment of traversing the yellow ligaments, and this, overcome with gentle pressure, the instrument penetrates into the rachidian canal; immediately a few drops of clear liquid are seen to issue from the free extremity of the needle, which is a sufficient indication that the operation has been successfully accomplished.

When the desired quantity of liquid is drawn off, the needle is withdrawn rapidly and the cutaneous orifice closed by collodion or a simple application of tincture of iodine.

As to accidents, lumbar puncture is in general an inoffensive operation, yet cases of death rapidly following the operation have been reported by Minet and Lavoix, who published accounts of 35 cases which occurred in France and other countries. However,

these deaths were especially observed in subjects suffering from cerebral tumours and in cases where a too large quantity of liquid was evacuated.

Headache is frequently observed and vertigo, rachialgia convulsions, vomiting, have been reported. But these symptoms seldom extend over 10 or 12 hours.

Certain precautions, however, should be observed in lumbar puncture, which, according to Dr. Sicard, are as follows:—Refuse to operate on any patient suspected of cerebral neoplasm, in whom functional disturbance, nausea, vertigo, and headaches are notably exaggerated in the horizontal position; leave the patient in bed 24 hours before operating; operate only in the lateral decubitus; leave the patient in bed 48 hours after the operation, lying on the back with the head low; remove, unless otherwise indicated, no more than one or two drachms of liquid at a sitting; employ a fine needle.

##### SIMPLE TREATMENT OF PHIMOSIS.

A simple treatment of phimosis is advocated by Dr. Thevemon, that of forcing back with gentle pressure the foreskin over the glans, a little each day; at the end of 6 or 8 days the difformity is corrected. Care should be taken against using too much force, or being in too great a hurry, for fear of creating paraphimosis.

Before operating, five or six ounces of a solution of boric acid should be injected between the prepuce and the glans to facilitate dilatation, as no attempt should be made at traction before the anterior extremity of the glans is visible.

The method is painless and well tolerated by children.

#### GERMANY.

Berlin, August 22nd, 1909.

##### SOCIETY OF GERMAN SCHOOL MEDICAL OFFICERS.

THIS Society was founded last year in Darmstadt, and its first annual meeting coincided with that of the German Society for School Hygiene, the annual meeting of which was held in Dessau in June last.

At this meeting Hr. Cuntz, of Wiesbaden, discussed the uniformity of health certificates, and laid down bases for arriving at some degree of uniformity. He desired first of all to have careful notes of the diseases children had already undergone on commencing school; (2) a watch over the course of these diseases; and (3) determination of the fact of any new diseases and a watch over their course. Subsequent examinations of all the school classes should be made at the end of the second year, or at the latest the third, and in any case in the eighth or last year. In all the later examinations a note must be made as to the general bodily development, as "good," "medium," "bad." The meeting agreed that principles such as those brought forward by the speaker ought to be adopted. They would aid in fulfilling the aims and requirements of school hygiene. They desired that they should be adopted and acted on in their unchanged condition.

##### NATURAL RESISTANCE TO TUBERCULIN.

The *Deutsche Med. Wochenschr.*, 23/09, has an article on this subject by Dr. Pickert, of the Sanatorium for Diseases of the Chest, Beelitz. He says that by the help of the methods of procedure of himself and Loevenstein for testing immunity against tuberculin, it was shown that occasionally the serum of tuberculous patients that had not been treated specifically had the power of destroying or weakening the specific action of tuberculin on the skins of tuberculous individuals. This property of neutralising tuberculin was present in a marked degree in the serum of patients suffering from tuberculous phthisis, in whom the course of the disease was an abnormally favourable one, and it was evidence of unusual resisting power on the part of the individual. In such cases, by means of injections of tuberculin, a heightened resistance against tuberculin was shown. In the same way the failure of cutaneous inoculation with weakened concentration of tuberculin was in favour of a certain natural resistance against infection.

In any case the fact that the same neutralising

material was present in the serum of untreated phthisical patients whose course of the disease was a favourable one was a striking proof that Koch's tuberculin treatment, in the best sense of the word, was a natural method of cure; it only imitated Nature's method.

Prof. G. Neumann has a paper on

#### TUBERCULOSIS IN CHILDHOOD

in a journal called the *Jugendwohlfahrt*.

In childhood, he says, the tubercle bacillus first settles in the lymph glands. From here it passes further, into the bones, joints, the skin, etc. (scrofulosis).

Tuberculosis injures the health much more, but shortens or destroys life much less frequently in childhood than is generally believed. The part attacked is very important. Within the scrofulous organs attacked it is not immediately dangerous to life, but under certain conditions it may break out from them, and especially in the course of other diseases; it may then spread through the whole system, or attack a vital organ such as the meninges of the brain, and lead to a fatal result. This possibility arises mostly during the first year of life; the strong, developing youthful organism easily triumphs over the tuberculosis, notwithstanding its increasing frequency. The age from the twelfth to the thirteenth year is less frequently menaced by death than any other period of life, and although most of the few deaths at this period are from tuberculosis, this changes nothing as regards the triumph of youth over tuberculosis. It is only after this period that pulmonary tuberculosis makes its appearance more and more, when the lungs are more distinctly disposed to it, and when diseases of occupation set up inflammatory irritations, and when, perhaps, a new infection is added to one already existing. These three factors, which by their multiplication lead to unfortunate results, have naturally in the individual case a very varying importance. We should make inquiry in every case as to hereditary tendency to pulmonary tuberculosis, and in such a case and particularly as regards choice of calling, we should carefully avoid any injury to the lung, a very difficult task, as the necessity of earning a living associated with unfavourable home surroundings only rarely allows the possibility of normal work for the lung in the open air—i.e., not too heavy, nor yet work that entails too shallow breathing.

#### AUSTRIA.

Vienna, August 22nd, 1909.

##### GASTRIC DILATATION.

At the Gesellschaft für Innere Medizin, Müller and Saxl had a sort of co-operative reading on their experiments and examinations of dilated stomachs. When the organ has been stretched ten times its original size, each fasciculi of the muscle is not reduced thus in thickness ten times, but may be half of its original size by the increase of other fibres. The empty stomach is not flabby and soft, but rather a somewhat compact hollow organ, which requires some force to open. The normal filling by the reception of food is effected by a lower pressure in the organism itself, which is not present when the individual fibres are elongated and the surrounding resistance reduced. If an animal be narcotised, and a cannula placed in the pylorus, after this the superior laryngeal nerve irritated, allowing water at the same time to flow into the stomach, the slightest pressure will cause the organ to dilate; if the animal be not narcotised, a much higher pressure than the normal will be the result. They concluded from their experiments that the mechanism of tonus in the organ resided in the vagus nerve. Atony of the organ was due to a loss of resistance in the muscular sheath of the stomach from defective nerve supply.

If the Röntgen rays be applied, it will be seen the food is taken into the cardiac end of the organ at first, and is then gradually carried forward into the body of the stomach, where the more active turning is produced in the normal condition. In the atonic condition the food falls into the organ as into a sack, where the churning is of a feeble erratic condition. Anæsthetics

have this relaxing power of the stomach, while alcohol stimulates the organ into an active state at first, but gradually loses this power, and finally leaves it in a lower state than at first. Cold fluids do not seem to affect it either way, while warm fluids relax the organ, and mineral waters slightly increase the tonus.

#### EXPERIMENTAL ANÆMIA.

At the Physico-Medical Gesellschaft, Faust recorded a case of bothrio-cephalic anæmia, and how he succeeded in producing a similar anæmia by using about 130 grammes of the dried parasite in healthy persons, and producing a similar anæmia with the damaged blood corpuscles when microscopically examined. These were not affected by water, but dissolved in ether, showing their fatty nature. This ether extract contains phosphorus, which at first was considered lecithin, but closer investigation proves it to be cholesterolin, and the three fatty acids stearic, palmitic, and oleic.

The oleic acid seems to be most active, as a simple experiment on the dog will prove. If the acid oleate of soda be injected into the bowel it will be rapidly absorbed and produce the same hæmolytic change as the bothrio-cephalic substance did in the former experiment.

Faust further fed dogs on the oleic acid, and used it subcutaneously in guinea-pigs with the same result, that the red blood corpuscles were reduced as well as the hæmoglobin in those that remain.

The practical results of these experiments are demonstrated every day by some organ suddenly becoming poisoned through fermentative decomposition, when a fatty synthesis takes place and is rapidly absorbed, producing all the deleterious effects of the oleic acid, as described in the experiments. It seems this acid either arrests the production of the blood corpuscles in the bones and hæmatic organs, or destroys the function of the red blood corpuscle, which leads to anæmia.

#### HÆMOLYSIS OF STREPTOCOCCI.

Polano gave the Gesellschaft a lengthy description of his experiments with the streptococci, particularly in puerperal fever. Schottmüller, he said, had selected or, rather, isolated, three streptococci that were malignant, viz.: streptococcus longus, viridis, and mucosus. Frommel has gone so far as to announce that when the streptococcus longus is found in the blood or lochia the prognosis is bad. Polano now contraverts this statement, as he has found the streptococci in 30 cases that were quite normal and no sign of fever experienced. There was, however, in eight cases decided hæmolysis, which could only be attributable to the presence of the streptococci in the blood.

He thought the same might be said of sepsis, angina, scarlatina, and pneumonia, that finding of streptococci in the blood was not always an unfavourable sign.

#### MORBUS BARLOW.

Hochsinger reported a case of Barlow's disease in a child at the breast. From birth it had been fed on the breast, but gradually became pale and white, with pains in the legs and arms. The knees, ankles, and forearms at their distal ends were greatly swollen. The Röntgen rays revealed blood effusion into the sub-periosteal space, where the pain was located. The child was fed on Nestlé's milk, and the whole trouble soon disappeared. He thought this disproved the notion that sterilised milk was the cause of the disease.

## FROM OUR SPECIAL CORRESPONDENTS AT HOME.

#### BELFAST.

THE COMPULSORY NOTIFICATION OF TUBERCULOSIS.—As noted in this column several weeks ago, the Belfast Corporation has been considering the adoption of the Tuberculosis Prevention (Ireland) Act. The Public Health Committee of the Corporation hesitated to recommend its adoption till they were assured that

certain difficulties which they foresaw could be got over, and to settle the matter a deputation from the Committee waited upon the Local Government Board in Dublin last week. The principal points discussed were the notification of certain prescribed forms of tuberculosis, and the position to be occupied by the Medical Superintendent Officer of Health in the administration of the Act. Some doubt had been expressed as to whether this officer would have power of entry in cases when he might wish to verify a diagnosis. The Board replied that if the Act were adopted, so far as the Medical Officer of Health was concerned, he would be provided with ample powers to make it effective. He could, if he so desired and thought it his duty, visit, inspect, and inquire into every individual case, and make himself thoroughly satisfied that the person notified was suffering from tuberculosis, so as to be a source of danger to others, and that everything was being done, as laid down in the Local Government Board's order, to prevent the spread of the disease. The deputation reported to their Committee, and it was unanimously resolved to support the recommendation for the adoption of Part I. of the Act. There is no doubt that after this the adoption will be agreed to by the Corporation. Its working will be watched with great interest by local medical men. It is easy to see where friction may arise, but with a little tact there is no reason why it may not be avoided.

**LONDONDERRY LUNATIC ASYLUM.**—The annual report of this institution has just been issued by the resident medical superintendent, Dr. Hetherington, and contains several items of interest. The patients number 532, of whom 289 are males, and 243 females. The average cost of gross expenditure, less repayment of loans, was £26 os. 8d. per patient, being 9s. 10d. less than the previous year. The net cost after deducting all receipts was £19 15s. 3d. per patient. The farm accounts showed a profit of £377, after deducting an estimated rent of £404. There was no death from accident or suicide. There were 41 epileptics, but no cases of general paralysis. As regards causation, according to Dr. Hetherington, physical causes predominate over moral. Domestic trouble is the commonest of the latter class, while of the physical causes heredity is far the commonest, intemperance coming next. Only ten of the whole number of patients are described as well educated, the majority belonging to the farm labouring class, with farmers and factory workers next.

## LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

### THE DECLINING BIRTH-RATE.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—To Mr. Clement Sers I commend a study of the following facts:—The quarterly return published in the *Times* of this morning, August 18th, shows again that the birth-rate in the second quarter of this year is the lowest recorded since the establishment of civil registration. The fall at the present rate will render the population stationary in about twelve years. This has been proved by Dr. Carl Pearson within the past few weeks. The annual increase amounts now to a little over 400,000 only. The residuum of partially and complete unemployables—the physically, mentally, and morally unfit—is being diminished, and will further decrease with more complete application of scientific methods now becoming more and more extended by the State. More and more of our surplus are capable of being made fit for colonial life. In every district there are to be found great numbers of "unskilled" labourers, most of whom, with or without preliminary training, are quite fit to wield pick and shovel in the colonies. Many of these men are married, with broods of young children who would develop into superior citizens in their new homes. Canada could take the whole of our normal surplus for a hundred years. She, as big as Europe, with inexhaustible virgin resources, could support hundreds of millions; she now contains 7,000,000 only. Besides

Canada, we possess lands in Australasia, in Africa, and our minor colonies as big together as two more Europes. They also could take between them more than our surplus for another hundred years. New Zealand, with its fertile soil and perfect English climate under the Southern Cross, has less than 2,000,000 of inhabitants; she could support 40,000,000 or more. The Imperial system of emigration needed to take out and father the new-comers is being gradually evolved through the activity of colonial governments, and it is absurd to suggest that a population question exists in these islands except in the sense that we need to promote increase by every means, and at the same time, of course, prevent the undue influx of the alien. There is ample room for the alien as well as for our own surplus in our colonies; the danger at present is that our colonists may be swamped by alien races, and the Empire become in time British only in name. The next fact is that the limitation of the family prevails most among the wealthy, well-to-do, and well-bred—the people able to support and put out in the world the normal number of children—and that the motive (as in France) is egoistic, anti-social, and anti-patriotic. It is at once a sign and a further cause of moral decay. The ideal is luxury, ease, and the pursuit of pleasure. The suppression of the philoprogenitive instincts produces in both parents easily recognisable deterioration. The evil effects upon the one or two children owned by parents are equally conspicuous, and the marriage system among the well-to-do, which ensures a mate for every girl with enough money, however ill-fitted to be a mother, constitutes a gigantic system of artificial selection encouraging the production of the unfit. The next fact is that nations that decrease in numbers without becoming superior in quality to their rivals for the dominion of the world will sooner or later go down before them. The Germans have at home 68,000,000—that is, over 10,000,000 more than the number of people of European blood in the whole British Empire, including India. There are, besides, several millions of Germans abroad, who still remain citizens of the Fatherland. The evidence is overwhelming that the Germans from below upwards, in their various strata of population, stand, on the whole, on a higher plane of civilisation than our people. Mr. Sers can satisfy himself as to this fact by inquiry, if he does not now accept it. He will not fail to appreciate its significance.

I am, Sir, yours truly,  
A STUDENT OF SOCIOLOGY.

### ANEURYSM—AN ACCIDENT.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—The astonishing case commented on in your columns, of a workman who was held to have died of an accident through the bursting of an aneurysm of the aorta makes one wonder where the old divisions between disease and accident have vanished to. If the natural termination of a disease is an accident, then we must all of us die accidental deaths. Surely it is as much a disease-process for an aneurysm to burst as for one's heart to fail in syncope. I was present last week at the post-mortem of a man who died suddenly at his work, and the autopsy revealed extensive atheromatous change in the aorta and coronary arteries. The coroner's jury found—very properly—that death had taken place from natural causes, but I could not help wondering how the case would have been decided by the wisacres of the Appeal Court if it had come before them. We are not accustomed to look upon coroners' juries as founts of wisdom, but I cannot help thinking that their decision in this case was better medicine, and better law, than is to be found on the Bench of H.M.'s High Court of Appeal. If the matter were not serious we could look upon it as merely a little display of *scintilla juris*, but, seriously, I cannot consider that I was wrong when, sixty years ago, I pronounced the law a "hass."

I am, Sir, yours truly,  
BUMBLE.

August 23rd, 1909.

## OBITUARY.

### DR. VON BOLLINGER.

We regret to announce that Dr. Otto von Bollinger, ordinary professor of the medical faculty and Rector of the University of Munich, died there on August 14th. He studied medicine at Munich, Vienna, and Berlin, and took his degree of doctor in 1867. He then returned to Munich, and worked there for several years as assistant to the late Dr. von Buhl. For a short time he subsequently lectured on pathology at the Zurich University. But since 1874 he resided in Munich, and there acted at first as privat docent, but in 1889 was promoted to the post of ordinary professor of general pathology and pathological anatomy at the veterinary school and at the University of Munich. He was also Principal of the Pathological Institute of the Munich University. He was a prolific writer of medical works, among them being books on "Meat Poisoning" and on the "Heredity of Diseases." His chief works relate to the pathology of the mortification of the spleen, tuberculosis, actinomycosis, and also meat poisonings and infections through animal poisons. His chief work, "Atlas und Grundriss der pathologischen Anatomie," appeared in 1896. Dr. von Bollinger was also the co-founder and editor of the "Deutsche Zeitschrift für Tiermedizin und vergleichende Pathologie," a periodical which has appeared since 1875. One of Von Bollinger's special domains was the question of illnesses of the heart after habitual beer-drinking.

### DR. G. W. DAVIDSON DEEPING, M.R.C.S., L.R.C.P., L.S.A.

We regret to record that Dr. G. W. Davidson Deeping has died at Hastings, where he lived since retirement from active practice in 1900. He had previously been for about 30 years a prominent medical practitioner at Southend, where he was a surgeon to the local Victoria Hospital and an Admiralty surgeon.

In his student days at Guy's Hospital he was a triple prize winner for the years 1868-70 inclusive, and in the following year obtained a gold medal in medicine. Dr. Deeping has also been a house surgeon and a resident obstetric surgeon to the hospital. His qualifications included L.R.C.P. and L.S.A., obtained in 1871, and M.R.C.S. in 1872. He was a J.P. for the county of Essex.

## MILITARY & NAVAL MEDICAL NOTES.

### PENSIONS TO CIVIL SURGEONS IN MILITARY SERVICE.—

A decision of some importance to civil medical practitioners who may have served in South Africa during the late war, and may have subsequently been admitted by commission into the Indian Medical Service, has been promulgated. The Secretary of State for India, in communication with the Army Council, has decided that such service in civil capacity shall reckon towards service for Indian pension. Officers who wish to claim the concession, but who have not yet established their claims thereto, should submit their applications for verification through the usual channel, stating the period of their service in South Africa, and the capacity in which they served during the war in that country. This is a generous concession, for it could not be claimed as a right. It will bring pension much earlier in some cases.

**TERRITORIAL SICK AND WOUNDED.**—To understand the position as regards the provision for medical and surgical aid to the Territorial troops, the Secretary of State has issued to the Territorial County Associations a "Scheme for the Organisation of Voluntary Aid in England and Wales." The Associations are enjoined to place themselves in communication with the Council of the British Red Cross Society without delay, in view of initiating the formation of voluntary aid detach-

ments if it is not the wish of the associations themselves to undertake their formation and training. A summary of the "scheme" alluded to appears in most of the military papers, but is too long for reprint in this column.

**FEVER AND HILL SANATORIA IN INDIA.**—News comes from Burma that half the battalion of the Royal Irish Rifles quartered at Maymyo have had to be sent to different hill sanatoria owing to the prevalence of fever. Maymyo has not got, as far as we know, the reputation of being an unhealthy station, so the question arises whether there are insanitary conditions in or about barracks—e.g., damp floors, etc.—to cause unusual sickness.

**FIELD AMBULANCE.**—The Eastern Mounted Brigade Field Ambulance (R.A.M.C.) unit has been encamped on the South Dunes, Yarmouth, since the beginning of the month, and useful and instructive work has been performed. The total strength of all units is 107. Field ambulance work has been done during the greater part of the time, and the men are given credit for keenness to learn everything possible about the work. The Principal Medical Officer of the district paid a surprise visit to the camp, and found everything in perfect order. The collection of dummy wounded by stretcher squads, etc., etc., was also inspected by Colonel Babbie, V.C., Inspector Army Medical Service.

**VACCINE FOR DYSENTERY.**—At the proceedings of the Indian Tea Association, it was mentioned that, on the suggestion of a firm of tea planters, the Director-General of the Indian Medical Service had been asked for information with regard to a serum which, it was understood, was of considerable value in the treatment of dysentery. The serum was the preparation of a member of the Indian Medical Service, but was not available to medical officers in the tea districts. The Sanitary Commissioner to the Government of India, to whom the matter was referred, has stated that, pending the completion of a special inquiry into the etiology of dysentery in India, now in progress at the Central Research Institution, it was not considered advisable to issue dysentery vaccine.

**HILL SANATORIA IN INDIA.**—The severe sickness, following on last year's rainy season, throughout Upper India, has made a considerable demand for hill accommodation for soldiers' families this year. Much has to be said both *pro* and *con* the removal of these families from the plains to the hills on account not only of splitting up the home, but also on the kind and extent of accommodation provided in the hills. Increased hut accommodation in the higher ranges of hill stations is necessary, for the misery experienced in tents, large though they may be, in the rainy season, is very great. The families of the rank and file are, in these days, of a better class, and it is to the advantage of the Army that they should be well accommodated, while it is to the advantage of India that the children should be reared in healthy surroundings. Fifty years ago Surgeon-General Sir William Muir—then P.M.O. in India, and subsequently Director-General A.M.S.—suggested that most of the troops should be huddled in the hill stations and attend on themselves.

**PRACTICAL JOKING.**—Practical joking in the Army has not infrequently ended in anything but a joke, and that is a fatal ending. The regrettable accident by which a man lost his life quite recently at Maidenhead, and another man was injured at Fleetwood, through blanket-tossing, will probably tend to end this form of horseplay. A strict order has been circulated in the command to this effect. We have to thank the Press in some degree for popularising this form of horseplay by illustrating it, and, no doubt, unwittingly encouraging a risky game. Practical joking years ago was as common in the commissioned as in the non-commissioned ranks, but it is now so emphatically denounced by the authorities that its practitioners are in imminent peril.

**FIELD TRAVELLING KITCHEN.**—A great deal of interest is attached to a new field travelling kitchen. It is with the Royal Irish Fusiliers quartered at Salamanca Barracks, Aldershot, the headquarters of the School of Cookery. A report on its serviceableness will be presented to the Army Council after the manoeuvres now proceeding. The advantages of having food ready on arrival in camp are unspeakable, and if the success of the new kitchen be pronounced, its adoption will assuredly come about. Certain service utensils are separate, each of which can be carried on a wagon for the supply of a detachment.

## SPECIAL ARTICLES.

### COMPARISON OF LAWS FOR THE PREVENTION OF UNQUALIFIED PRACTICE.

We are indebted to the Registrar of the General Medical Council for a copy of the "Digest of Laws in the British Empire and Foreign Countries for the Prevention of Medical Practice by Other than Legally Qualified Persons." (a) The book is, in the main, a reprint of the Appendix to the Report of the Unqualified Practice Prevention Committee (November, 1908), but contains a good deal of information obtained since that Report was drawn up. Information is given with regard to the legal regulation of medical practice in Great Britain and its dominions and dependencies, and also in most foreign countries. These amount in all to 108.

The following 76 British possessions and foreign countries forbid the practice of medicine by unqualified persons, under penalty of fine or imprisonment:—Basutoland, Bechuanaland, Cape Colony, Natal, Orange River Colony, Transvaal, Western Australia, Alberta, British Columbia, Manitoba, New Brunswick, Nova Scotia, Ontario, Prince Edward Island, Quebec, Saskatchewan, Newfoundland, Cyprus, Gibraltar, Ceylon, Hong Kong, Straits Settlements, Gambia, Mauritius, Northern Nigeria, North-Western Rhodesia, Nyasaland Protectorate, Seychelles, Southern Nigeria, Southern Rhodesia, Swaziland, Bahamas, Bermuda, British Guiana, British Honduras, Grenada, Jamaica, Leeward Islands, St. Lucia, Trinidad, Turks and Caicos Islands, Fiji, Austria, Hungary, Belgium, Bulgaria, France, Greece, Italy, Montenegro, Netherlands, Portugal, Roumania, Servia, Spain, Switzerland, Turkey, Japan, Mexico, United States of America, Costa Rica, Guatemala, Honduras, Nicaragua, Salvador, Cuba, Haiti, San Domingo, Argentina, Brazil, Chile, Colombia, Panama, Paraguay, Uruguay, Venezuela. To these it is probable that six others may be added:—Malta, Egypt, Denmark, Norway, Sweden, Ecuador.

In the following twelve countries certain privileges are reserved to qualified practitioners, and medical titles are protected by the imposition of fine or imprisonment on persons wrongfully making use of such titles:—New South Wales, Queensland, South Australia, Tasmania, Victoria, New Zealand, Sierra Leone, Barbados, St. Vincent, Falkland Islands, Germany, United Kingdom.

The following twelve countries have no law regulating the practice of medicine:—India, Wei-hai-Wei, British East African Protectorate, St. Helena, Somaliland Protectorate, Uganda, Zanzibar, Cayman Islands, China, Persia, Abyssinia, Morocco.

In the Gold Coast and Russia the restriction of practice is limited to inability to procure patent drugs. In Peru unqualified practice does not seem to be penalised.

Answers are given in detail in reference to all the above countries to the two questions—(1) What constitutes a legal qualification to practise medicine and surgery? (2) What legal provisions exist for the prevention of the practice of medicine and surgery by persons not legally qualified? All the information thus given is further summarised into a table convenient for reference.

(a) General Medical Council. London: Spottiswoode & Co. June, 1909.

## REVIEWS OF BOOKS.

### THE ANALYSIS OF FOOD AND DRUGS. (a)

THIS valuable monograph of "The Aids Series" has unfortunately been out of print for some time, Mr. Pearmain having died shortly after the appearance of the last edition. Mr. Moor has now obtained the services of Mr. Partridge as co-author, and the present edition is, to all intents and purposes, a new book, for there are innumerable changes and additions. The writers are well-known as authorities on their subject, so that we do not require to convince our readers as to the general accuracy of the statements made. We wish, however, to emphasise the great practical utility of a small compendium such as this, which condenses, summarises, and brings together a vast amount of information such as can only be obtained after much search through larger volumes and treatises. Too often we find such aids to study, contemptuously set aside by the reviewer as if they only encouraged indolence on the part of the student. This cannot be said of the present volume. The authors' statements in no sense resemble those of the mere cram-book. They are intelligent, scientific, and accurate, if condensed, as they must of necessity be.

This small book covers the entire ground of foods and drugs analysis, including even soap and urine, which are not quite of this nature. Only the most valuable modes of laboratory investigation are referred to, and the methods given are fully detailed without unnecessary remarks or padding. Throughout the volume suitable references are made to the various Acts dealing with sampling and adulteration. We cannot speak too highly of the lucid style in which the book is written. It is a model of what such aids should be. The book obviously appeals more particularly to candidates reading for diplomas of public health or for the F.I.C. examination. To all such we can heartily recommend this small volume. It is not only handy for study and reference, but is complete in itself. We might almost venture to suggest, though we are not a little afraid to do so, that a knowledge of the contents of this book, supplemented by the necessary practical work, will be found sufficient for all ordinary examination purposes. At all events, we may safely say that it may be used with great advantage as an aid to revision a week or two before the ordeal. It would be hard indeed, if not impossible, to write a better or more accurate summary of the subject than is given us in the present volume. We congratulate the authors on the superiority of their work, which is bound to make itself felt by those who take our advice and make good use of it.

### GYNÆCOLOGY AND ABDOMINAL SURGERY. (b)

THE two large volumes dealing with gynaecological and abdominal surgery which have been produced under the guidance of Drs. Howard Kelly and Noble, call for no unstinted meed of praise. Indeed, the names of so many distinguished surgeons and gynaecologists associated with the various chapters in the books is sufficient guarantee of the work's value. The first volume is devoted entirely to gynaecology, and is in every way excellent, the names of the authors of the different sections being: Brooke M. Anspach, J. M. Baldy, Henry Byford, John G. Clark, George Edebohl, William Ford, Anna Fullerton, F. Heurotin, G. Hunner, Elizabeth Hurdon, Howard Kelly, B. MacMonagle, Charles P. Noble, Alexander Skene, J. C. Webster, and X. O. Werder.

The illustrations are profuse, and the production all that could be desired. The chapters are excellently written, and concise and clear in their expression, the one dealing with the operative procedure in the radical treatment of carcinoma uteri being very well done,

(a) "Aids to the Analysis of Food and Drugs." By C. G. Moor, M.A. Cantab., F.I.C., Public Analyst for the County of Dorset and the Borough of Poole; Public Analyst for the City of Exeter, and William Partridge, F.I.C. Third Edition. Fop. 8vo. Pp. vi., 249. London: Baillière, Tindall and Cox, 1909. Cloth, 3s. 6d. net. Paper, 3s. net.

(b) "Gynaecology and Abdominal Surgery." Edited by Howard A. Kelly, M.D., F.R.C.S. (Hon. Edin.), and Charles P. Noble, M.D. Philadelphia and London: W. B. Saunders Company. 1907-08.

and the various steps shown by a sequence of admirable drawings. It is, of course, a necessity to find statements made throughout a work of this kind, where the individual opinions of each writer are expressed, somewhat at variance when treating subjects that are akin. For example, we find that while the Alexander-Adam operation is in one place highly approved, in another it is not thought so highly of, and ventro-suspension advised in many instances in its stead. Yet in the end these differences are of really small account, and the reader can decide for himself what mode of procedure to adopt.

The second volume forms a worthy companion to the first, dealing with complications following operations, Cæsarean section, operations during pregnancy, extra-uterine pregnancy, intestinal surgery, stomach, gall-bladder, pancreas, etc., the authors responsible for the chapters being B. M. Anspach, J. C. Bloodgood, John M. Finney, Barton Cooke Hirst, G. L. Hunner, Elizabeth Hurdon, G. Ben Johnston, Howard Kelly, Edward Martin, Floyd McRae, G. Brown Miller, B. G. A. Moynihan, J. B. Murphy, Charles P. Noble, R. Norris, Albert Ochsner, Eugene Opie, J. F. W. Ross, Stephen H. Watts, J. Whitridge Williams. These chapters contain most able expositions of *technique*, and, coupled with the illustrations which we have been taught to expect, appear to make some of the major operations almost easy.

Perhaps some of the illustrations are unnecessary, and certainly those portraying a multitude of hæmostats and little else are not the least instructive. Surely diagrams would have more clearly expressed the meaning. Drs. Howard Kelly and Charles P. Noble have always set themselves a very high standard, and this is fully maintained in the present volumes. Gynæcologists and surgeons owe already a large debt of gratitude to their efforts, and this is distinctly added to by their latest achievement, which should undoubtedly find a place in the libraries of all interested in operative work.

#### STUDY OF DISEASE IN CHILDREN. (a)

THIS volume contains the record of the work of the Society for the Study of Disease in Children for the past session, and with it closes the history of the Society as a separate entity. For the future the Society will be known as the Section for the Study of Disease in Children of the Royal Society of Medicine. During the past nine years the Society has done excellent work, and, to judge from the record in the volume before us, there should be a brilliant future before it under its new foster-parent. If the members of the Section will continue to produce work such as is given to us in the present volume, they will add in no little measure to the value of the Transactions of the Royal Society of Medicine. We fully sympathise with those members who wished to maintain the Society on the original lines that had proved so successful, but we believe that the decision arrived at was a wise one, and that, as a Section of the Royal Society of Medicine, an even wider sphere of usefulness will be opened to the old Society.

#### THE STEREOSCOPIC ATLAS OF OBSTETRICS. (b)

THIS volume concludes the Edinburgh Obstetrical Atlas, and provides students with a most interesting and well executed series of photographs of normal and pathological obstetrical conditions. The Atlas makes no attempt to embrace the entire subject of obstetrics, but, so far as it goes, it is admirable. One thing we miss. We are promised on the title-page a preface by Sir Halliday Croom, but we have not succeeded in finding it in any of the sections we have received.

Section IV. contains twenty-five stereoscopic photo-

(a) "Reports of the Society for the Study of Disease in Children." Vol. VIII. Session of 1907-8. By George Carpenter, M.D. 8vo., pp. lxxviii. and 504, seventeen plates. London: J. and A. Churchill, 1909.

(b) "The Edinburgh Stereoscopic Atlas of Obstetrics." Edited by G. F. Barbour, M.D., F.R.C.P. Edin., F.R.C.S. Edin., Senior Assistant to the Professor of Midwifery in the University of Edinburgh, and Edward Burnet, M.B., B.Ch., with a Preface by Sir J. Halliday Croom, M.D., F.R.C.P. Edin., Professor of Midwifery in the University of Edinburgh. Section iv. London: The Caxton Publishing Company, 1909.

graphs. The first half-dozen deal with breech, transverse, and face presentations. There is then a very admirable photograph of a "pendulous belly." Next come three photographs of Cæsarean section. Two of these are not very happy, as the blood obscures the field. The remainder of the Section consists of photographs of such conditions as placenta prævia, accidental hæmorrhage, retained placenta, abortion, ectopic gestation, bi-cornute uterus, and hydatidiform mole. Some of them are extremely good, particularly those taken from specimens lent by Prof. Harvey Littlejohn.

We have great pleasure in congratulating the Editors on the result of their labours, and on the effective manner in which they have dealt with a difficult subject.

#### ADVICE TO A WIFE. (a)

THIS well-known work has now reached its 15th edition, and has completed a sale of 390,000 copies. The present edition has been thoroughly revised and brought up-to-date by the editor, Dr. Robinson. He appears to us to have done his work carefully and well, and at the same time to have preserved the original style of the book. We are glad to note that he has also added a note on the frequency of cancer of the uterus, and the urgent necessity for immediate attention to any symptoms which suggest its presence. On the other hand, we do not know that it was necessary to put into the mouth of Dr. Chavasse a denunciation of "bridge" as one of the causes of ill-health in women! We are sure the present edition will be at least as popular as its predecessors.

#### GYNAKOLOGIE. (b)

GERMAN writers vary so much in their styles of writing that even those who have a good working knowledge of the language are at times put to great trouble to find out the true meaning of the author. It is therefore a pleasure to find a book containing such excellent matter so simply and clearly expressed. The "Gynäkologie" of Professor Gottschalk is a most delightful handbook, the matter is thoroughly explicit and put shortly, though it loses nothing by this, while the arrangement of things is admirable. Copious illustrations help to explain the text. It is interesting in these days to find that, though many gynæcologists object to pessaries as being useless and harm-working, that Professor Gottschalk still finds a place for them in modern gynæcology. *À propos* of this, it is worthy of notice that Fig. 14, after Hofmeier, illustrates a Hodge pessary *in situ* better than almost any other. The little volume is very well printed, and is a most convenient size.

## LABORATORY NOTES.

#### ALLOSAN.

WIEDEMANN, BROICHER AND CO. have submitted to us samples of Allosan, the allophanic ester of santalol. It does not represent a salt of an acid santalol ester, but it is the ester itself. For the esterisation of the santalol, allophanic acid ( $C_2H_4N_2O_3$ ), is employed. This acid was discovered by Liebig and Woehler, and given its name by them in 1849 (*alloe pavesey*, to appear different). Liquid bodies of objectionable taste or odour can, through esterisation by this acid, be changed into solid, tasteless, odourless, and non-irritant bodies. Allosan has the formula  $NH_2CO, NH, CO, OC_{15}H_{23}$ ; it is a white powder of agreeably mild and aromatic odour; it is without taste, and is perfectly non-irritant as regards mouth, oesophagus, stomach, intestinal canal, or kidneys, it does everything that Santalol does. It has the action of a good and faultless balsamic, and is being much used in the treatment of gonorrhœa.

(a) "Chavasse's Advice to a Wife." Fifteenth Edition. Revised by G. Drummond Robinson, M.D., F.R.C.P., Physician to the British Lying-in Hospital, Physician for Diseases of Women to the West London Hospital. London: J. and A. Churchill.

(b) "Gynäkologie." By von Professor Dr. Sigmund Gottschalk, Berlin. Wien und Leipzig: Alfred Hölder. 1909.

## SUMMARY OF RECENT MEDICAL LITERATURE, ENGLISH AND FOREIGN.

*Specially compiled for THE MEDICAL PRESS AND CIRCULAR.*

**The Function of the So-Called Motor Area of the Brain.**—Sir Victor Horsley (*Brit. Med. Journ.*, July 17th, 1909) states that, although he had frequently observed the effects of comparatively small lesions in the pre-central and post-central gyri, it was not till last year that he obtained the first example of an absolutely pure lesion of one of these gyri alone—namely, the gyrus pre-centralis, and one which, by repeated examinations, the writer satisfied himself afforded the final proof of the position advanced—namely, the sensori-motor character of that convolution. The case was that of a boy, æt. 14, who had had no illness and suffered no accident, but at the age of seven had gradually developed athetoid movements of the left hand, which then developed into violent convulsive movements of the whole upper limb. When the limb was quiet the purposive or voluntary movements were normal and powerful. The reflexes and sensation were also normal. On March 20th, 1908, the right Rolandic area was exposed. Electrical stimulation of the gyrus post-centralis produced no results, but stimulation of the pre-central gyrus produced the various movements of the left upper limb. The whole pre-central gyrus was removed. Briefly summed up, the effects in this case of the removal of the so-called motor centres for the upper limb in the gyrus pre-centralis were as follows:—Immediate: Disappearance of spasmodic movements; complete loss of voluntary movements of the left upper limb; post-axial and proximal atropognosis of the same; complete astereognosis of the left hand; moderate anæsthesia to all forms of sensation of the left upper limb. Remote (*i.e.*, a year later): Permanent absence of spasmodic movement; partial recovery of voluntary movements of the left upper limb; proximal atropognosis of left post-axial fingers; astereognosis of the left hand; slight tactile anæsthesia of the ulnar periphery of the left hand. The author concludes, in summing up, that:—(1) The so-called motor area of the human cortex cerebri is really sensori-motor. (2) The gyrus pre-centralis is in man the seat of representation of (a) slight tactility, (b) topognosis, (c) muscular sense, (d) arthric sense, (e) stereognosis, (f) pain, (g) movement. (3) The gyrus post-centralis is in man part of the arm area in which the sensory-motor function is of the same kind as that in the gyrus pre-centralis, but in it probably the provision for sensory co-ordination is greater, and that for efferent impulses less. (4) The giant pyramids of Betz cells are not essential for the performance of purposive or voluntary movements. (5) Purposive or voluntary movements can be performed after complete removal of the corresponding part of the gyrus pre-centralis. S.

**The Seriousness of Genital Lesions in the Male dating from or before Puberty.**—Eugene Fuller (*Post-Graduate*, July, 1909) has found that in that class of young men who as a rule have been grouped as neurasthenics, a little specialised questioning will bring to light the fact that the sexual function is crippled and deranged. In some of these cases there is a history of gonorrhœa contracted during boyhood, or of the sexual function being actively developed at a tender age. Local examination shows the penis and testicles well developed, and the prostate normal. The seminal vesicles, however, will feel small, and the tissues in the post-prostatic space about them more dense and inelastic than normal, even suggesting a condition approaching sclerosis. In the writer's opinion, repeated sexual acts in the patient's childhood causes an inflammatory reaction to be developed in the seminal vesicles, and the resulting exudates becoming organised into fibrous tissue, the vesicles being bound by adhesions are only partially developed. The author has operated on seven cases. He exposes the seminal vesicles, and

freed them of the old inflammatory adhesions, thus giving the organs a chance of expanding and developing. In all cases they have been drained to guard against a possible atonic distension, which might well result after the attenuated sac walls had been dissected free from their enveloping tissues. Five cases were operated on more than a year ago. They have been signally benefited. The mental symptoms have disappeared and the sexual power has returned. In the two recent cases the mental symptoms have disappeared, but the sexual power had not returned, as it does not in such cases for nine months or a year after operation. The primary object of the operation is the removal of the mental and nervous symptoms, thus making it possible for the individual to become self-supporting, the restoration of sexual disability being secondary. S.

**A Case of Adeno-Myoma Uteri.**—Purslow (*Journ. Obst. and Gyn. Brit. Emp.*, XVI., 1).—An abdominal supra-vaginal hysterectomy for multiple fibroids was done. The specimen was a typical example of multiple fibroids of the uterus. The separate tumours were cut across and had a firm white appearance with the exception of one small sub-peritoneal tumour from the posterior cornu, this had a softened area in the centre about  $\frac{1}{2}$  inch in diameter surrounded by firm white tissue, the central area having a much darker appearance under the microscope, the softened area showed typical adenomatous tissue, *viz.*, numerous gland spaces lined by a single layer of columnar epithelium and having a cellular inter-alveolar stroma. This adenomatous tissue was sharply defined and did not spread into the surrounding mass, which was ordinary fibromyoma. The growth resembled closely the tumours described by von Recklinghausen, the origin of which is ascribed by him to Wolfian rest cells. F.

**Further Observations on Transfusion, with a Note on Hæmolysis.**—Crile (*Surg. Gyn. and Obst.*, IX., 1).—The physiological adjustment of the altered quantity of blood in the donor and the recipient is greatly facilitated by the use of tables either end of which may be lowered or elevated. It is found that contrary to common belief, normal blood of one individual does quite as well as that of another. Kinship is of no special advantage. The heart has proved itself to be the most important consideration in transfusion, when the recipient's heart presents a lesion to which there has been developed a compensating hypertrophy, this muscle is presumably working near its maximum, its normal factor of safety therefore may be almost wholly lost. If the circulation of an ex-sanguinated patient is rapidly recruited by fresh blood under a full head pressure from the radial artery of the donor, there will be an immediate and striking improvement. It is just at this point that the greatest caution is necessary; the anæmic myocardium may be unequal to performing the increased burden thrown upon it and dilatation may follow. If acute dilatation occurs the head-down posture must be maintained to supply the brain, although the reverse position would relieve the dilated heart. When the heart recovers the head may be raised and after about 10 minutes the flow of blood may be restarted slowly. The most effective active measure to overcome an acute dilatation is rhythmic compression of the chest. Once the first stage of the anæmia of the myocardium is passed but little further trouble need be anticipated until the normal volume of blood has been regained. There are two notable groups that have shown themselves susceptible to

results, one in which there has been internal hæmorrhage, the other, in which the patient has been reduced by long continued disease to such a degree as to render an operation unsafe. In these cases the donor is attacked and enough blood transferred to render the recipient safe for an anæsthetic. Blood can be transferred as needed during the operation, and at the end of the operation, to ensure safety of the circulation. The author has transfused 18 cases for tuberculosis. In most of these the donor's blood hæmolyzed the blood of the recipient in the test tube but not in the patient. He concludes that though there is hæmolysis in vitro it does not follow that there will be necessarily in vivo. F.

**Acute Infective Endocarditis treated by a Vaccine.**—Conder (*Practitioner*, Aug., 1909) records a case of acute pneumonia in a man, æt 43, which was complicated by acute infective endocarditis which was treated by a vaccine prepared from the patient's own blood and ended in recovery. This complication in acute pneumonia is not rare, Osler found it present in 16 out of a 100 autopsies, and states that it "seems to be of an unusually malignant type." The patient was attacked with an acute pneumonia involving the lower lobe of the right lung. Previous to this, he had a lesion of his mitral valve resulting from an attack of rheumatic fever in childhood, but did not suffer from any disturbance of the circulation. The *Diplococcus Lanceolatus* (Pneumoniæ) of Fraenkel was recovered from the sputum, and later on pure cultures of this organism were also recovered from the patient's blood. Five days after the onset of his illness the patient was injected with a dose of vaccine containing 50 millions of his own pneumococci. Three days later a similar dose was given and then at intervals of three days, doses containing 100 million cocci were given. After this the infective process appeared to be at an end, and no further injections were given. During the period of administration of the vaccine, the opsonic index was taken and the following results were recorded. On the day of the first injection 1.01, on the next day, 1.04, later on during this day it had risen to 2.90, subsequently it declined somewhat and after the last injection was 1.28. The diagnosis of acute infective endocarditis in this case was based on the following observations, (1) The evidence of former valvular disease; (2) the presence of acute pulmonary inflammation; (3) the occurrence of repeated rigors, and subsequently of repeated profuse sweats; (4) the sudden development of a loud, rough cardiac murmur in the course of the pneumonia; (5) the irregularity of the temperature; (6) the extreme embarrassment of the heart, (7) The ease with which the organism was obtained from the blood, the loud rough systolic murmur persisted after the recovery of the patient, though the acute dilatation of the heart quite disappeared. K.

**A Remedy for Paroxysmal Tachycardia.**—Fairbrother (*Journ. Amer. Med. Assoc.*, July 24th, 1909) records a form of treatment that he has found effective in cutting short attacks of this distressing condition from which he has suffered since childhood. In his earlier life the paroxysm averaged about one a month, but for the past twenty years about one a week. Their duration varied from a few minutes to twenty-four hours, the frequency of the heart-beat rising from 72 to 140 or 200 a minute. About a year ago he discovered accidentally on being compelled to run quickly to catch a street-car during an attack, that the exercise was followed by a sudden cessation of the frequency of the heart-beat. Since that time he has repeated the observation and now is always able to cut short the attack at once in this way. Instead of running however, which he found sometimes inconvenient, he has adopted energetic skipping movements, from 60 to 100 of these being usually sufficient to end the attack. Dr. Fairbrother says "It is simply the producing a sufficient volume of blood in the heart to overcome the nerve tangle which is the cause of the trouble. Now, as I have followed this practice, with invariable success,

for almost an entire year, and covering about fifty attacks, I feel safe in giving it to the profession as a remedy." K.

**Successful Omentopexy in Cirrhosis of the Liver.**—(*Intercolonial Med. Journ.*, June, 1909).—White records the history of this interesting case. The patient, a child, æt. 9, had been in delicate health since birth, and for about eighteen months previous to her admission to hospital had suffered from an increasing swelling of the abdomen. She had never been tapped before admission to hospital. The child's parents were temperate but the mother stated that on account of the delicate state of the child's health she had been in the habit of giving her from half to three table-spoonsful of whiskey each day. The Wassermann serum test for syphilis gave a negative result. After admission to hospital the child was tapped five times at intervals of a fortnight, but only with temporary relief. The abdomen was then opened and the operation of omentopexy performed. The liver was found in a typical hobnail condition and the spleen was considerably enlarged. After the operation, the child was tapped three times in five weeks, but after that, marked improvement set in and further tapping was not necessary. Two months after the operation, the child appeared in good health and all signs of ascites had disappeared. K.

## MEDICAL NEWS IN BRIEF.

### A Fortune for the Pasteur Institute.

In a few days the Pasteur Institute will receive the large sum of £1,200,000, which was bequeathed to it by the late M. Osiris. M. Osiris, who was a rich and philanthropic Jew, founded in 1903 a triennial prize of £4,000 to be bestowed on "the person who had rendered the greatest service to the human race during the three preceding years." The prize was awarded to Dr. Roux, the head of the Pasteur Institute, for the discovery of the "anti-diphtheria serum," which has been the means of saving the lives of many thousand children. The millionaire was much astonished to learn that Dr. Roux had made over the whole of the money to the institute of which he is the head, although he is a poor man with a salary of some £250 a year, and lives in a very small apartment, for which he pays £24 a year rent. M. Osiris was so much struck by the unselfish conduct of the man of science that he made the doctor's acquaintance, and they became firm friends. M. Osiris one day asked him why he had given the money to the institute.

"All that I am," replied Dr. Roux, "I owe to the Pasteur Institute, for all my experiments and discoveries have been made there. Besides, the institute is very poor, for we have no income except what we make by the sale of serums, and though that brings in enough to keep the establishment going, some fresh remedy may any day be discovered, in which case I fear the institute would have to close its doors for want of funds."

The millionaire said nothing at the time, but at his death, which occurred a year or two afterwards, it was found that he had left the bulk of his wealth to the Pasteur Institute, as a token of admiration for the scientific attainments and self-abnegation of Dr. Roux.

### Death under Anæsthetics.

At the Paddington Coroner's Court, Mr. W. Schroder held an inquest on George Thomas Lipscombe, aged 53, a shop porter. In the middle of March he came home and complained of pains in the side. He told his wife that he was standing on a pair of steps, on the stairs, cleaning a mirror, when the steps gave way, and he fell on a bar and hurt his head, ribs, and arms. There were several bruises, so witness went with him to St. Mary's Hospital, where he was treated. Since that time he had attended regularly for treatment, although he still continued work until five weeks ago. On July 30th he was admitted for the purpose of an operation for a growth in the neck, and

witness knew that he would be given an anæsthetic. She heard of his death on Friday. Mr. William C. Loudon, manager of the Edgware Road branch of the firm, said the man had been there for seven years. He could not ascertain that anyone saw him fall, and he certainly made no complaints that his illness was caused by an accident on their premises.

Dr. Bryan, of the hospital, said the man was admitted on the 23rd ult., although witness knew that he had previously been treated there. He was suffering from a tumour on the right side of the neck. He was given an anæsthetic, but the operation had not been commenced when the patient suddenly ceased to breathe, and, despite all efforts, died very shortly afterwards. He had since examined the body, and found the heart muscle diseased and degenerated, which would render it liable to sudden failure. There was a large tumour in the neck, attached to the muscle, and continuous with the glands, probably of a tuberculous nature. Death was due to heart failure, when under the influence of anæsthetics. It was possible, but not probable, that an injury might have caused the formation of the blood cyst in the neck.

Walter Warren, porter at Messrs. Gardiner's, said the deceased was standing on a ladder in the mechanics' department in the basement, cleaning and polishing the woodwork of the staircase, when it slipped from beneath him and he fell with it a distance of seven or eight feet, striking his head on the gas heater. Witness assisted him. His eye was cut, but he continued his work. He did not strike his shoulder. Since that time they had arranged amongst themselves that someone should hold the ladder, when cleaning high up. They never used safety grips. Geo. Henry Davey, another porter, corroborated, and said the extension ladder was full out at the time. Deceased complained of pains in the face. The coroner adjourned the inquiry in order that the result of the microscopical examination of the kind of tumour might be known.

#### Midwife Fined.

A PROSECUTION under the Midwives Act, 1902, came before the Mayor (Ald. Taylor) and other magistrates at Mansfield on August 18th, when Dinah Ann Peace, of Bould Street, was summoned by the Notts County Council.

Mr. J. H. White appeared to prosecute, and said Mrs. Peace had got her name placed on the midwives' roll, which was the only roll for properly certificated midwives, but owing to certain circumstances, which it was not necessary to go into, her name was removed, and was not on the roll for the year 1909. The complaint was that, although her name had been removed from the roll, the defendant continued to put out a plate which bore words to the effect that she was a certificated midwife, and she also exhibited in her window a certificate stating that she was a certified midwife.

Dr. Handford, Medical Officer of Health for Notts, was called, and, in cross-examination by Dr. Tarachand, said the defendant was not qualified to call herself a certified midwife after her name was removed from the roll, notwithstanding the fact that she had a certificate.

Dr. Tarachand then directed his cross-examination to the complaints made against the defendant, but Mr. White objected, on the ground that it was irrelevant. Dr. Tarachand, however, said he "wished to expose a flagrant act of injustice."

Inspector Chandler, Sergeant Dye, and P.C. West spoke to seeing the brass plate and certificate exhibited in the defendant's window during the month of June last, and Supt. Rodgers deposed that he attended an inquest at Mansfield on May 25th, when Mrs. Peace gave evidence.

For the defence Dr. Tarachand said Mrs. Peace was entitled to act as a midwife, and to exhibit her plate, inasmuch as she had received a certificate from the Lying-in Hospital, City Road, London. The defendant had attended more than 300 cases with no ill-effects to the patients, and it was to be regretted that such a capable and hard-working woman should be deprived of her right to earn her living through certain trivial

irregularities in not observing the rules of the Board, such irregularities being the result of her inability to write, and not her inability to practise.

Dr. Tarachand called Miss Lessy, the inspector of midwives for the county, and caused some amusement by his request to treat her as a hostile witness before she gave evidence. The witness admitted that defendant had attended numerous cases, and that, so far as she was aware, the patients had gone on all right. Counsel then questioned witness on the entries in defendant's register, and she mentioned certain reports and complaints she had made.

The Bench imposed a fine of £2 and costs.

#### Diphtheria in Yorkshire.

LAST year an outbreak of diphtheria in Pateley Bridge, West Riding, caused considerable anxiety in the township of Bishop Thornton and the hamlets in the vicinity. A number of cases were notified, and the matter assumed somewhat alarming proportions before a check could be put to it. The outbreak necessitated the closing of the Church of England schools at Bishop Thornton, where many of the children in the district attend, and, in consequence of suspected infection at a later period, the schools have been closed for a greater portion of this year.

Representations were made to the authorities, with the result that an inspection of the drainage of the locality was carried out. That action in the matter is needed is emphasised by a further crop of cases in the small hamlet of Shaw's Mill, in the Bishop Thornton township, four new cases having been reported during the past fortnight. The sufferers were at once removed to the Pateley Bridge Isolation Hospital, and the Pateley Bridge Urban District Council, alive to the dangers of a second epidemic, are promoting a scheme for the improved drainage of Shaw's Mill. Land, it is understood, has been acquired lower down the valley, and the scheme is to cost about £800.

#### The Health of Southwark.

THE Medical Officer of Health for the Borough of Southwark (Dr. G. B. Millson), in his annual report, states that the estimated population of Southwark at the middle of 1908 was 210,442. The death-rate was 16.3 per 1,000, as against 18.0 in 1907. The birth-rate, 28.1 per 1,000, was the lowest in the history of the borough. In 1900 it was 33.3 per 1,000. The infantile mortality was 131 per 1,000 births, the lowest figure ever recorded; much of this had been brought about by the disposition at the present time of mothers to breast-feed their children, and to the Notification of Births Act, 1907. Of infectious diseases, cerebrospinal fever had proved fatal in 6 cases. The number of cases of diphtheria was the smallest on record, and there had also been a considerable reduction in the mortality in tuberculosis during the last seven years. The mortality was, however, still very high. The deaths from phthisis were 414.

#### Cholera at Stockholm.

A STOCKHOLM merchant who had been on a visit to St. Petersburg was taken ill with cholera last Thursday. The case, however, says Reuter, is a very mild one. The invalid is still isolated, although he appears to have been in perfect health during the past few days. No other case has occurred, and the sanitary condition of Stockholm is most excellent. Tourists are beginning to return to Stockholm, and the large hotels, which during the last few weeks have been empty owing to the strikes, are now full.

#### Doctor's Sudden Death.

MR. JOHN TROUTBECK held an inquiry at Battersea on August 19th, concerning the death of Dr. James Edward Mennie, aged thirty-one, of Queen's Road, Battersea. The widow stated that Dr. Mennie had been taking chloral since November to induce sleep. He had a very busy day on Monday, and in the evening he went to lie down. At bed-time he remarked that he had forgotten to take his medicine. He returned a few minutes later and went to sleep. His heart was beating very quickly, but suddenly it ceased, and she sent for

a doctor. A servant deposed to having heard Dr. Mennie say that if the hot weather lasted it would kill him. Dr. Trevor, pathologist, said that death was due to heart failure, while Dr. Mennie was suffering from degeneration of the heart accelerated by a dose of chloral. He was in such a state that a dose of chloral which might have been taken with safety at ordinary times would prove fatal. The jury returned a verdict of accidental death.

#### **New Examination Hall for the London Medical Colleges.**

As referred to in a previous issue, the negotiations which have been pending between the Royal College of Physicians of London and the Royal College of Surgeons with regard to the acquisition of a site for a new examination hall, the present building on the Victoria Embankment having been sold by the two colleges to the Institution of Electrical Engineers, have now been completed. The site chosen for the erection of the new hall is at present occupied by four houses in Queen Square, Bloomsbury. It is understood that one of the houses will be adapted for the use of the Imperial Cancer Research Fund, and that the pulling down and re-building operations will occupy about three years. Meanwhile, the examinations for the conjoint diplomas of these colleges will still be conducted at the hall on the Victoria Embankment, rooms having been temporarily leased to the colleges by the Institution of Electrical Engineers.

#### **Municipal Bacteriology.**

THE return for the six months ended June 30th, just issued by Dr. Priestley, Medical Officer of Health for Lambeth, shows that the medical men of the borough are taking advantage of the facilities afforded by the municipal laboratory to enable them to diagnose any doubtful cases that may come under their observation. Dr. Priestley makes these examinations free of charge to medical men in the borough. During the six months 109 tubes of sputa were examined for tuberculosis, and 273 specimens of throat and nose membranes and discharges for diphtheria.

#### **Liverpool City Hospitals.**

THE Medical Officer of Health for Liverpool, and the Medical Superintendent of the City Hospital, Fazakerley, together with the City Treasurer and Controller, have just issued annual reports with regard to the city hospitals. From these it appears that at the present time the number of beds available in the various hospitals is as follows:—North, 162 beds; South, 100; East, 152; Parkhill, 235; Fazakerley, 350; and Fazakerley Annexe, 160; total, 1,159. The value of the hospitals and the immense amount of useful work performed is shown by the fact that no less than 6,213 patients were treated within their walls, the great majority of these being cases of scarlet fever. The report further states that steps have been taken by the committee to render the training of probationer nurses more efficient. Probationers are received at some, but not all, of the city hospitals, and under the arrangements now arrived at the system, which includes lectures as well as practical and clinical instruction, will render the course of training a very full and complete one. Fifty beds at Fazakerley are now devoted to the treatment of cases of tuberculosis. Evidence is not yet available to show how far the disease has been permanently arrested in those patients who have been discharged from hospital, but a system is adopted by which these patients shall present themselves at regular intervals for examination. Visits by inspectors of the health department to the houses of patients result in a continued observance of those hygienic methods which the patients have acquired in hospital so far as their circumstances permit. The report gives interesting and valuable statistics of the number of cases and types of disease dealt with in each of the city hospitals.

#### **The Metropolitan Asylums Board.**

THE report on the work of the Metropolitan Asylums Board during the year 1908, submitted at a recent meeting of the Board, is a source of some satisfaction. During the financial year ended at Michaelmas, 1908,

the net expenditure of the Board was £1,121,942, being a decrease of £13,841, as compared with the previous year, although the average daily number of inmates maintained was 485 in excess of the average of the previous year. For the second year since its establishment in 1867, it was not found necessary to raise any loan in respect of building or other works, and its indebtedness on existing loans was reduced by £181,745, leaving the capital indebtedness at £3,025,044, while the estimated value of its property exceeds double the amount.

The total number of patients admitted into the Board's fever hospitals during the year were—from scarlet fever, 19,629, with a mortality of only 2.56 per cent.; diphtheria, 5,230, with a mortality of 9.73 per cent.; enteric, 509, with a mortality of 16.28 per cent.; typhus, 2, with no deaths; cerebro-spinal meningitis, 3, with 1 death; other diseases, 2,594, with a percentage of 5.68 deaths.

#### **A Magisterial Pronouncement on Vaccination.**

ON Friday last Annie Rebecca Telford was summoned at Bow Street Police Court for unlawfully and wilfully giving false information to a deputy-registrar concerning the birth of her child.

The false information was given for the purpose of evading the Vaccination Acts. The practice of making false statements of this kind for the purpose of avoiding vaccination was a growing one, and in consequence the Registrar-General had ordered these proceedings to be taken. The defendant, who had made false statements on two previous occasions, now pleaded guilty, and said that she had acted as she had done as she dreaded vaccination. She had lost one child through vaccination, and she was afraid of losing her youngest one in the same way. It was very delicate.

Mr. Curtis-Bennett (the Magistrate) said that the defendant might be mistaken as to what caused the death of her child. He (the Magistrate) had been vaccinated four times, and was ready to be vaccinated again if necessary. If the defendant's child was too delicate for vaccination she should take it to a doctor, who would have the operation postponed if necessary. The defendant was liable to a penalty of £10, but she would only have to pay 20s. and 23s. costs. The defendant said that she was very poor, and the Magistrate granted her time for payment.

#### **A Death under Spinal Anæsthesia.**

AN inquest was held on Friday last, at Clerkenwell, on the body of a child, aged 1 year and 4 months, who had been received into the Great Ormond Street Children's Hospital to undergo a necessary surgical operation. A requisite preliminary to this was the administration of an anæsthetic, and on Tuesday, after a spinal injection of stovain, and before the operation was commenced, the child suddenly expired.

Mr. G. E. Ward, F.R.C.S., who made an autopsy, ascribed death to respiratory failure consequent on collapse of the lungs, and whilst the child was under the influence of the anæsthetic.

Dr. Gray, Hospital Superintendent, said that in the circumstances stovain was the best possible anæsthetic. He could not say that the stovain took no part in accelerating death. He had injected stovain in 200 cases.

The Coroner asked if spinal anæsthesia was on the increase, and was answered in the affirmative.

A verdict of death by misadventure was returned.

#### **Requests to Medical Institutions.**

A LARGE sum, which, after payment of legacy duty and other expenses, will probably amount to about £43,000, has been bequeathed under the will of the late Mr. Edwin Joseph Alfred Ayliffe, of Paris and London, who died on July 10th, to 26 charitable institutions, among which the following hospitals will receive about £1,500 each:—London Hospital, Royal Free Hospital, Westminster Hospital, Charing Cross Hospital, Middlesex Hospital, St. George's Hospital, University College Hospital, Cancer Hospital, Hospital for Consumption, North-Western Hospital, Chelsea Hospital for Women, Metropolitan Ear Hospital, Friedenheim Hospital (Swiss Cottage, N.W.).

## NOTICES TO CORRESPONDENTS, &c.

**OUR** CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

### SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs 15.12. Messrs. Dawson and Sons are our special agents for Canada.

### ADVERTISEMENTS.

FOR ONE INSERTION:—Whole Page, 25; Half Page, 23 10s.; Quarter Page, 21 6s.; One-eighth, 12s. 6d. The following reductions are made for a series:—Whole Page, 13 insertions, at 23 10s.; 26 at 23 3s.; 53 insertions at 23, and pro rata for smaller spaces.

Small announcements of Practices, Assistances, Vacancies, Books, &c.—Seven lines or under (70 words), 6s. 6d. per insertion; 6d. per line beyond.

ORIGINAL ARTICLES OR LETTERS intended for publication should be written on one side of the paper only and must be authenticated with the name and address of the writer, not necessarily for publication but as evidence of identity.

CONTRIBUTORS are kindly requested to send their communications, if resident in England or the Colonies, to the Editor at the London office; if resident in Ireland to the Dublin office, in order to save time in reforwarding from office to office. When sending subscriptions the same rule applies as to office; these should be addressed to the Publisher.

J. G. SWAIN (Wolverhampton).—Curiously, shortly after the receipt of your letter, a public announcement was made of the report of a sub-committee of the King Edward's Hospital Fund for London, upon the subject of charity entertainments. While it shows that neither extravagance nor abuse exist to any large or general extent, it, nevertheless, advises the perusal of its report which may be of service where proposed entertainments are under consideration.

### NOVA ET VETERA.

In the new Indian monthly "Medico-Chir. Journal of the Tropics," edited by S. K. Mullick, M.D.M.S., Edin., there is an interesting article on pregnancy, and the native superstitions connected therewith. During an eclipse the pregnant women remain inside their houses. One corner of their sheet is dyed with turmeric to keep off the evil influence of Raksh the demon, and a wooden pestle is kept loose for them to frighten him away. No harm can be done to those who take such preventive measures in due time.

They avoid passing under haunted trees, for fear that the child will be born with "feet presentation." Various kinds of charms are employed to protect the women during pregnancy. Wearing of glass bangles of green colour is recommended and after the seventh month an iron bangle too is added to them to strengthen their magical properties. From the eighth month wearing of cloths, of two bright colours and smelling of strong sweet odours are left off. Cutting of nails too is discontinued. When the time of delivery approaches near, pregnant women cannot participate in the worship of the drum if any marriage is celebrated in the house. The drum inside is empty and touching it during this period is liable to cause premature birth and emptying the womb from the precious load before its proper time. The writer also describes some very amusing devices by which women try to find out before birth, whether the child would be male or female.

M. J. H. (Leeds).—The cases referred to go to prove the uncertainty of the law, but the extraordinary divergence of opinion among the judges concerned in its administration. Why one woman should be sentenced to ten years' penal servitude for an "illegal operation" and another under exactly similar conditions to twelve months, is an enigma that can be explained only by the judges concerned. We cannot enlighten you.

### A ROYAL M.D.

ONE of the few Royal medicine men is having his seventieth anniversary royally celebrated in Bavaria. Duke Charles Theodore, M.D., is not only a popular Prince, but a more than popular practitioner. His mission in life declared itself somewhat late. He was eight-and-thirty when he entered the Munich faculty as a student; and there were those who laughed and chaffed at the notion of this mature student really meaning business. Duke Charles Theodore, however, not only meant business, but got it. He was soon in the enjoyment of a large practice at Tegernsee, and only retired from it when he specialised as an oculist, and started a "Klinik" in the Bavarian capital. Now his name and fame are great throughout the Fatherland.

When the Kaiser met with that unfortunate accident aboard his yacht in northern waters, and the return end of a rope inflicted a dangerous back-hander on the Imperial eye, it was at the desire of the Kaiserin that Duke Charles Theodore was called in, and it was he whose treatment restored the injured optic. Naturally, the Duke has ever since been regarded with a favourable view in high quarters, and, naturally also, his practice has increased, until now the Munich "Klinik" hardly suffices for its daily crowd of patients.—*Pall Mall Gazette*.

A YORKSHIRE PRACTITIONER.—According to reliable, but non-official, estimates, midwives now conduct about half the confinements in England and Wales. In Ireland and Scotland the proportion is considerably smaller.

## Appointments.

BROWNE, FRANCIS JAMES, M.B., Ch.B.Aberd., District Medical Officer by the Bedwellty (Mon.) Board of Guardians.  
DAYSON, FREDERICK ADAMS, M.D., C.M.Aberd., M.R.C.S., Deputy Port Medical Officer of Health for the Dartmouth and Totnes (Devon) Port Sanitary Authority.  
DRAKE, JOHN ALEXANDER, M.B.Lond., M.R.C.S.Eng., L.R.C.P. Lond., Medical Officer to the Post Office at Tenby.  
HAMILTON, ROBERT, M.D.Edin., Junior Assistant Medical Officer at Sunnyside Asylum, Montrose.  
MCKAIL, DAVID, M.D.Glasg., D.P.H., Lecturer on Hygiene to Nurses in Training in the Glasgow Royal Infirmary.  
MACKAY, D. MATHESON, M.D., C.M.Edin., M.R.C.S.Eng., L.R.C.P. Lond., Honorary Assistant Ophthalmic Surgeon to the Hull Royal Infirmary.  
MOLE, H. F., F.R.C.S.Eng., L.R.C.P.Lond., Surgeon to the Royal Infirmary, Bristol.  
SCALES, F. SHILLINGTON, B.C.Cantab., Honorary Medical Officer in Charge of the Electrical Department at Addenbrooke's Hospital, Cambridge.  
SMITH, G. MUNRO, L.R.C.P., M.R.C.S., Consulting Surgeon to the Royal Infirmary, Bristol.

## Vacancies.

Essex and Colchester Asylum, Brentwood.—Fourth Assistant Medical Officer. Salary £150 per annum and board. Applications to the Medical Superintendent.  
Rotherham Hospital and Dispensary.—Assistant House Surgeon. Salary £80 per annum, with rooms, commons, and washing. Applications to the Secretary, G. W. Roberts, 8, Moorgate Street, Rotherham.  
Royal Victoria Eye and Ear Hospital, Dublin.—House Surgeon. Salary £40, with board and residence. Applications to Edward Parker, Registrar (see advt.).  
The Manchester Northern Hospital for Women and Children, Park Place, Cheetham Hill Road.—House Surgeon. Salary £80 per annum, with apartments and board. Applications to Mr. Hubert Teague, Secretary, 38 Barton Arcade, Manchester.  
Norfolk and Norwich Hospital.—House Physician. Salary £80 per annum, with board, lodging, and washing. Applications to Frank Hasell, Secretary.  
Wolverhampton and Staffordshire General Hospital.—House Surgeon. Salary £80 per annum. Board, lodging, and laundry provided. Applications to J. S. Neil, House Governor and Secretary.  
Sunderland and Durham County Eye Infirmary, Sunderland.—House Surgeon. Salary £210 per annum. Applications to J. F. Potts, Secretary, Sunderland and Durham County Eye Infirmary, Stockton Road, Sunderland.  
Queen's Hospital for Children, Hackney Road, Bethnal Green, E.—Resident Medical Officer. Salary £100 per annum, with board, residence, and washing. Applications to the Secretary.  
Nottingham General Dispensary.—Two Assistant Resident Surgeons. Salary £160 each, with apartments, attendance, light, and fuel. Applications to C. Cheesman, Secretary, 12, Low Pavement, Nottingham.  
Staffordshire General Infirmary, Stafford.—Assistant House Surgeon. Salary £82 per annum, with board, residence and laundry. Applications to Richard Battle, Secretary.  
Brentry Certified Inebriate Reformatory, Westbury-on-Trym, Bristol.—Superintendent. Salary £300 per annum, with board and quarters. Applications to the Hon. Secretary, 34 Westbourne Gardens, London, W.

## Births.

BURTON-BROWN.—On August 17th, at Old Orchard, Iver, Bucks, the wife of Gerald Burton-Brown, M.D., Surgeon R.N., retired, of a daughter.

## Marriages.

MACKENZIE-RIGBY.—On August 18th, at the Parish Church, Blackburn, James Mackenzie, M.B., C.M., Colne, Lancashire, second son of Alexander Mackenzie, Esq., of Oromarty, N.B., to Marion, only daughter of the late George William Rigby, Esq., and youngest daughter of Mrs. Ann Rigby, of Blackburn.

MACKESSACK-COLEMAN.—On August 11th, at St. Clement's Church, Ourepipe, Mauritius, Major Peter Mackessack, R.A.M.C., eldest son of John Mackessack, of Kinloss, Torres, to Margaret, daughter of the late Alfred Coleman, F.R.C.S., and Mrs. Coleman, 9 Inverna Gardens, Kensington, London. (By cable.)

POWELL-PARISH.—On August 18th, at St. Augustine's, Edgbaston, George William Powell, B.A., M.B., fourth son of the late John Allman Powell, M.D., of Roscrea, Ireland, to Mabel Winifred, elder daughter of Henry Parish, of Bavelhill Edgbaston.

## Deaths.

TAYLOR.—On August 19th, suddenly of heart failure, Frederic Taylor, L.R.C.P., M.R.C.S., L.M., of 43 Beauchamp Road, S.W., formerly of Woodstock, Oxon, aged 78 years.

## NOTES AND COMMENTS.

### The Dublin Hospitals.

THE Report of the Board of Superintendence of the Dublin Hospitals, which we summarise in another column, contains some points of special interest. The Board, in particular, draws attention to the fact that the out-patient departments have not kept pace with the wards in modern progress. This is entirely true, and the cause is, to some extent, the lack of funds. On the other hand, it is possible that the hospitals increase their own difficulties by attempting too much, and in wrong directions. They attempt too much in that they try to swell the number of those relieved without due regard to the question whether the relief could not have been given equally well by other agencies. There is no doubt that many of the patients attended in the out-patient rooms of the Dublin hospitals could have been attended equally well by private practitioners, whom they are quite able to pay. The function of an out-patient department should be to provide relief where difficulties of diagnosis or of treatment put cases outside the scope of the general practitioner. It is not, therefore, by treating a large number of cases of chronic bronchitis or of constipation that a hospital renders service to the community. It is rather by attending to cases which require either expensive apparatus for their treatment or specially expert knowledge. Yet we doubt if there is more than one of the Dublin hospitals which contains a properly-equipped department for carrying out vaccine treatment, and not all the general hospitals contain X-ray departments. Yet it is only by work of this sort that the out-patient department fulfils its function. The suggestion that by co-ordination more satisfactory results could be attained contains some truth, but until the hospital authorities come to a saner view of the proper scope of their activities, little real improvement can be expected.

### Hospital Grants in Dublin.

It has been the custom for many years for the Corporation of Dublin to make grants, amounting in all to a little over five thousand pounds, in aid of certain of the city hospitals. The money has been well spent, for the hospitals are, on the whole, economically managed, and it is hard to over-rate the services they render to the city. It would seem, however, that for some time past there has been a certain jealousy aroused by the fact that the hospitals do not limit admission to residents of the city, but that many of the patients come from a distance. We have no means of stating what proportion of the patients come from the country, but the percentage must, on the whole, be small. At any rate, there is no justification for the statement recently made in a

resolution proposed to the Corporation by Mr. Quaid, that "the City Hospitals receiving the said grants are practically of no benefit to the poor of Dublin, but are almost entirely for the advantage of country patients." This gentleman proposes to cut off all the grants to the city hospitals, but so far he has not succeeded in gaining the ear of the Corporation. The fact is that the public have got so accustomed to the voluntary hospitals undertaking work which would otherwise fall on the rates, that they hardly recognise any of the debt they owe to the hospitals. If the Dublin hospitals were to close their doors tomorrow, the expense thrown on the rates would be something very much more than the five thousand pounds at present coming from that source.

### The G.M.C. and Unqualified Practice.

DURING the past few years the General Medical Council has shown more evidence of its concern for the interests of the profession and the public than it had previously exhibited. This is a change we cordially welcome, for the General Medical Council possesses, outside the profession an influence no unofficial body can at present hope to equal, and while the General Medical Council remained inert or uninterested, one could hardly hope for reform from outside. Since the last meeting of the Council an important volume has been issued by its authority, giving a great deal of detailed information with regard to the laws regulating medical practice in other countries. We abstract some of the essentials in another column. It will come as a surprise to many to learn that in no less than eighty-two out of one hundred and eight countries of which information could be gathered, practice by unqualified persons is penalised by fine or imprisonment. In only twelve do conditions similar to those in the United Kingdom exist. This comparison brings clearly to our view how much behindhand in the protection of the public we are in these countries. Moreover, of the eighty-two countries which prohibit unqualified practice, no less than forty-one are under the British Crown. The colonies are therefore for the most part far in advance of the mother country, though it is true that some of the more important, such as some of the States of Australia, and also New Zealand are in much the same condition in this respect as the United Kingdom. The General Medical Council has

THE attention of readers is drawn to an important question put to the Home Secretary in the Commons by Captain Craig as to the sale of quack medicines. This is printed, together with the answer, on page 232 of the present issue.

performed a useful act in collecting and making available the information in this volume. We trust its activity will not cease at this point.

**Medical Men  
and  
Dispensing.**

At the recent British Pharmaceutical Conference in Newcastle-on-Tyne there was a discussion—in which some medical men took part—on the question “Should Dispensing of Medical Prescriptions be Confined to Pharmacists?” In reading through the speeches we find that the claim is being made that medical men should voluntarily give up—or be deprived of—the right to dispense their own medicines. To a certain extent we find ourselves in agreement with those who argued in this sense. The dispensing of medicines by medical men often occupies time which might be better spent, and it is usually insufficiently remunerated. On the other hand in many country districts there are no chemists and it becomes an absolute necessity in the public interest for medical men to dispense their own medicines. At any rate, it is absurd to suggest that there should be a law to prevent them doing so. Pharmacists must remember that their craft is not an independent one, but is auxiliary and subsidiary to the profession of medicine. As well might nurses meet and discuss whether, let us say, the making of beds or the administration of enemata—once, by the way, the function of the apothecary—should be confined to trained nurses. “Pharmacists,” says Mr. Tocher, who introduced the discussion, “are members of the only class in the Kingdom specially educated and properly trained to prepare and dispense medicines.” This might be said *mutatis mutandis*, with equal truth, of chauffeurs and the driving of motor-cars, but the chauffeurs have not yet suggested that medical men should not be permitted to drive their own cars.

**The Malvern  
“Hydro”  
Case.**

THE final stage in the now well-known Malvern “Hydro” case is the bankruptcy of Dr. J. C. Fergusson, the late proprietor. Readers will remember that in 1904 several visitors at the Hydro contracted typhoid fever, which, being attributed to the water supply, was considered to create a liability against Dr. Fergusson, which he settled by paying sums amounting to £6,500. In the meantime, the reputation of the Hydro had, of course, sustained much damage, and Dr. Fergusson claimed against the Malvern Urban District Council as the water authority for the neighbourhood. It was held that the water caused the outbreak, but the question of liability turned on the common law right of a predecessor of Dr. Fergusson to use a certain pipe for the conveyance of the water. The jury found in his favour, giving £7,500 damages against the District Council. Against this verdict the latter successfully appealed on the technical ground of the right to use the particular pipe, and the appeal was upheld in the House of Lords. The result was that Dr. Fergusson found himself saddled, not only with £6,500 in claims by the typhoid patients, but with £6,500 law costs of the Council, an almost exactly similar amount for his own costs, and over £1,000 costs of witnesses, besides having his once prosperous business as proprietor of the Hydro reduced to small proportions. The story is a sad one in the extreme, and we much sympathise with Dr. Fergusson. The jury evidently did the same, but the verdict was set aside on the technical point mentioned. We trust that his son, who is now carrying on the business, will be able to restore its popularity.

### ENTOMOLOGY AND TROPICAL DISEASES.

ON Thursday last the Colonial Office made public the fact that a Committee had been appointed with the object of promoting the study of economic entomology, with special reference to Africa. Lord Cromer has consented to act as chairman, and the Committee consists of some twenty members, all leading scientific men, including Sir David Bruce, Sir Patrick Manson, and Sir John Macfadyen. The appointment of this Committee forms a sign of the times. It seems that the reproach which, up to late years, has justifiably been levelled at Government for neglect of science is now to be gradually, or speedily, removed, and that in future, whatever party be in power, the advice and help of men of science will be more and more sought in every direction in which it may be called for. To Lord Crewe, it appears, the credit for initiation of the present movement must be given, the establishment of the Committee being the outcome of a conference to which he invited a number of distinguished entomologists a few months ago. Members of the Committee give their services gratuitously; they have organised themselves into three sub-committees, each charged with a special division of the work. As every mere reader of current periodical literature is aware, our knowledge of the subject of the conveyance of disease by insects has enormously increased within the last few years. It has been demonstrated that such diseases in man as malaria, plague, sleeping sickness and yellow fever, are all conveyed by insects, whilst a long list of diseases in cattle and poultry have been traced to similar sources. Almost as much damage is done by insects that prey upon the crops, so that the future of Africa as a home for white men must depend very largely upon the destruction of these pests. Funds are to be provided by a grant from the Treasury, and contributions from the African Colonies most concerned in the work of the Committee. As might be expected, cordial offers of assistance have been made by the several schools of tropical medicine, and by the Universities, and help is confidently expected from workers in this branch of service in Egypt, the Sudan, and in South Africa. Mr. A. E. C. Parkinson, of the Colonial Office, is secretary to the Committee, and Mr. Guy A. K. Marshall has been appointed scientific secretary. Entomological experts are to be appointed and sent out to East and West Africa with the least possible delay, and it is confidently expected that these gentlemen will receive the assistance of colonial medical officers having full knowledge of the conditions that prevail in their respective localities. When we consider the truly wonderful practical results that have already been achieved by the application of scientific methods in stamping out disease caused by insects, we cannot doubt its ultimate triumph in the vast regions of savage Africa. We recently commented upon the remarkable results brought about under United States officials in Panama, one of the most recent

illustrations of the power of steadily-applied scientific methods. By these methods yellow fever has been done away with throughout the Tropics, and wherever they have been efficiently brought to bear, as in the Campagna, at Ismailia, and in many other widely-separated lands, intermittent fever has been virtually abolished. The tasks of preventive medicine in these directions, which until late years seemed impossible, are really becoming merely a question of expense, and as the outlay will lead to a return many millionfold greater, there should be no doubt about the provision of funds. Happily, in this instance, the encouragement and extension of colonisation and commerce will carry along with them the prevention of infinite human suffering, misery and waste of valuable life.

#### REPORT OF THE MIDWIVES COMMITTEE

WITH commendable promptitude, the Report of the Departmental Committee appointed by the Lord President of the Council at the end of last year to inquire into the working of the Midwives Act, has been issued. It is now six years since the formation of a Central Midwives' Board and the coming into operation of the Act. They were instituted to administer, and considering the curious policy which the members of the Board have followed, and dissatisfaction expressed in many quarters with regard to their decisions, the inquiry came none too early. In saying this, we must not be supposed to be criticising the actions of the medical members, who, on the whole, have acted with consistent dignity and restraint; unfortunately, the same cannot be said of all the lay members. The first conclusion arrived at by the Departmental Committee is one of satisfaction that the Act has worked so well, and has done so much to forward the objects aimed at. Praise, moreover, is given to the conduct of the Board, which is said to have been characterised "by judgment, prudence and sympathy," to which is added the curious statement that the Act has gained the good-will, not only of the local authorities, but, except in some instances, of the representative of the medical profession. On that last point we venture profoundly to differ from the Committee. No doubt the Act, in certain respects, marks an advance on the old haphazard and disgraceful methods prevalent among so-called midwives, but its fatal defect, which the Committee take no steps to remove, is that midwives' and midwifery practice among the poor are withdrawn entirely from the control of medical men. We have never been among those who believe that the midwife could be eliminated at one fell swoop from society, but while she exists it should be obvious to the meanest intellect that she is a person of severe limitations, and that so long as she continues to practice on her own account, those limitations will be constantly, nay, habitually, overstepped. Midwifery is a complicated science and a difficult art, organically connected with the practice of medicine and surgery, and every attempt to divorce from the province of medicine and to set up an independent order of practitioners, not only fails logically, but is bound

to fail in practice. Our own view, and we venture to say, the view of the profession generally, is not that the midwife should be a practitioner who calls in a medical man when she gets into a mess, but that she should be the assistant of a medical man, who is himself primarily and directly responsible for the conduct of each case. This view we shall never cease to hold, however much training may be insisted upon in the case of midwives. Training is all very well in its way, but no training of three months, six months, or a year will ever turn out a midwife competent to practice who is ignorant of anatomy, physiology, medicine and surgery. The Departmental Committee favour the retention of administrative powers in the hands of the County Council, and recommend that when dedication has taken place to district councils, such power should be withdrawn. As to the supply of midwives, the Committee take a roseate view, and they repudiate the suggestion that that part of the Act which comes into operation a year hence should be postponed. On the question of medical fees the Committee admit a real and substantial grievance as suffered by the profession. Figures were supplied by Dr. Howard Jones, Medical Officer of Health, Newport, Mon., showing that the practitioners in his district had attended an average of nearly twenty-eight patients each on the summons of midwives, many of them being difficult instrumental labours. In half of these no payment of any kind was made. In eleven per cent. small sums were paid, and in the remainder only was the proper fee forthcoming. One practitioner only received fees in twenty per cent. of the cases attended by him. The Committee recommend that in all cases the local Poor-law authority should be responsible for payment. It is something in these days when medical services are at a discount, except when required in emergencies, that even this amount of recognition should be accorded to them.

#### CURRENT TOPICS.

##### The Local Government Board and Food Supplies.

THE Local Government Board is an admirable institution; if it only had the real power of administration which its name suggests it might speedily bring about what is commonly termed a "millennium" in the national life, in so far as the public health is concerned. Unfortunately, the Board's functions begin and end in little more than compiling reports, pointing out defects, and recommending improvements. The duty of putting the laws in force lies with local authorities, and it depends entirely upon their intelligence and goodwill whether any part, and, if so, how much, of the admirable sanitary legislation which has been constructed during the past few decades shall be brought to bear in the respective districts wherein they exercise their powers. In many places the essential provisions of public health Acts are ignored; in many more they are administered with the utmost laxity; in comparatively few districts, whether urban or rural, is a continuous effort made to safeguard the health of the people by all the means available. The

fault lies upon the public. The majority of capable men, as a rule, decline to serve on local governing bodies, or even to take part in selecting and electing suitable candidates, and consequently there exists in many places no public opinion to influence the authority. Democratic institutions cannot be effectively worked under such conditions; in too many places they are lamentable failures. In these circumstances it seems a little doubtful whether the new department of the Local Government Board formed two years ago, and charged with the investigation of questions relating to the nature and quality of food supplies, will be able to achieve very much. It is not likely that authorities which cannot be induced to incur the expense involved in such simple, yet essential, matters as supervision of the milk supply, will provide the outlay needed for systematic examination and analysis throughout the whole field covered by the older Foods and Drugs Acts, and the Public Health (Regulations as to Food) Act, passed in 1907. This latter Act conferred new powers in regard to making regulations for the prevention of danger to public health arising from the preparation, storage and distribution of articles of food and drink. In the meantime, the Local Government Board has been conducting, through its own officers, inquiries in several directions. Dr. MacFadden has reported on the presence of lead and arsenic in imported tartaric acid used in the manufacture of beverages. Dr. Hammill has inquired into the adulteration and misdescription of vinegar. This is often merely a faked solution of citric acid, instead of the product derived from the brewing of malt worts. Dr. Buchanan and Dr. Schryver have reported on the use of food "preservatives." They have shown that these are often added to food or milk in such quantities as to cause danger to health; and they have proved that there goes on a large trade in meat and provisions in a state of incipient decomposition, the smell, staleness and putrefaction of which have been overcome by preparations such as formaldehyde.

#### The "Times" on Secret Remedies.

IN our issue a fortnight ago we noticed the recently-published Report of the British Medical Association on so-called secret remedies, quack nostrums which, when they contain any medicinal constituents at all—by no means always the case—yield up their secrets easily to the processes of analytical chemistry. We expressed the hope that the Report would be put before the newspaper Press in a manner that should compel the attention of editors and proprietors. Ignorance is the only excuse newspapers can allege for aiding and abetting a traffic which, as we have over and over again shown, is not only fraudulent but cruel and murderous; and the publication of the Report of the Australian Commission, followed now by the Report of the British Medical Association, takes away the power of any paper to put forward such an excuse. The *Times* sacrifices an income of thousands a year in closing its columns to a large class of puffs freely admitted into nearly every other paper, but it has recently shown itself far from as fastidious in this matter as it once was. Formerly—much more frequently than in late years

—it took occasion periodically to expose and denounce quackery, and to deplore "the enormous expenditure upon the quacks and quack medicines which undermines the health of so many victims, and which brings about the still greater evil of maintaining in prosperity and luxury some of the most complete and finished of the many imposters who are parasitic upon modern civilisation." In its Literary Supplement of Thursday last the *Times* thus briefly dismisses the British Medical Report:—"The British Medical Association has done a public service in publishing an exact statement of the cost and contents of all the most extensively advertised patent medicines. The prime cost of a bottle or box of pills rarely exceeds a fraction of a penny." The *Times* has missed an opportunity of forcing upon the attention of its contemporaries the facts with regard to this nefarious traffic with which members of its editorial staff have always been fully acquainted; but it is yet not too late to take the question up. The medical papers cannot, without the lay press, bring the facts before the public. The *Times* could do this alone with complete effect, and to do it, we are certain, would pay the leading journal in every sense of the word. Such a course would restore to the *Times* the prestige and respect which it has undoubtedly in late years to some extent forfeited, and it would yield to the proprietors the satisfaction of feeling that they had added one more to the large number of great benefits conferred upon the public by their renowned paper over a long series of years.

#### Dr. Hadwen on Malta Fever.

THAT distinguished physiologist, pathologist, anti-vivisectionist and anti-vaccinationist, Dr. Hadwen, has contributed a letter on Malta fever to the *Standard*. In it he speaks of his paper on the same subject in the *Contemporary Review* for August. We have not read that paper, nor do we propose to do so; the *Standard* letter is quite enough for us. Dr. Hadwen gives us to understand that the elaborate research, with its multiplied experiments, and control experiments, carried out by Sir David Bruce is entirely fallacious. Goat's milk has nothing to do with Malta fever, and the belief that Malta fever has been extinguished, in consequence of withdrawal of this milk as an article of diet by the garrison, is a pure delusion. The method of reasoning which has developed the delusion is neither logical nor scientific, but is full of fallacies and pitfalls. To say that Malta fever has been wiped out among the military and naval populations since imported condensed cow's milk has been substituted for goat's is mere special pleading. The fact is that, owing to the mental and moral obliquity which characterises the school of pathologists represented by Sir David Bruce, this school are now simply setting down the cases of so-called Malta fever—which Dr. Hadwen states is really not Malta fever at all, but only ordinary tropical fever—as simple continued fever. This is all very sad; it indicates a lamentable waste of force, and a position of stultification for Sir David Bruce and his colleagues. We doubt not that on receipt of the news of this pronouncement of Dr. Hadwen, Sir David Bruce will abandon his work in investigation of sleeping

sickness, on which he is now engaged, and will at once hurry home from Uganda, if only to make amends to Dr. Hadwen, and to avail himself of the knowledge and learning that he has evidently too long neglected. He will no doubt also relinquish his F.R.S. which was conferred upon him for his supposed discovery of the origin of Malta fever, and request Mr. Haldane to withdraw the thanks which, as Minister of War, he offered Sir David on behalf of the Government in the House of Commons for the services he had rendered in putting an end to a vast amount of human suffering, and saving at least two or three hundred thousand pounds annually to the national exchequer.

#### The Water Supply of London.

THE recently-issued Sixth Annual Report of the Metropolitan Water Board contains a mass of statistics in which only some few items are of interest to sanitarians. It is, however, satisfactory to note, first of all, the great advantage that has resulted from the consolidation of the numerous small independent authorities into one responsible body fully equipped for its duties. The main sources of water supply continue to be the rivers Thames and Lea, gravel beds in the Thames valley and at Hanworth, and natural springs and wells sunk in the chalk and other strata both north and south of the Thames. The total amount of water supplied during 1908-9 amounted to 81,823 million gallons, an average daily supply per head of population of 31.94 gallons. The storage reservoir capacity possessed by the Board amounts to 8,844 million gallons; this capacity is to be increased in time to 14,844 million gallons. The quality of the water is watched over by a Director of Water Examinations. The Report strongly emphasises the fact that the habitual use of stored water lightens the grave responsibility of the Board as regards the safety of the water supply, and tends to create a sense of security among those who watch over the health of the metropolis. The dissemination of water-borne diseases ought, at any rate, to be now much less possible than in the old days of haphazard methods and divided responsibility.

#### The Government Laboratory.

DR. THORPE, F.R.S., the principal chemist of the Government Laboratory, has just issued his Report for the year ended last March. It is a detailed statement of a truly stupendous amount of work, the gross total of the analyses carried out being 329,649. The work done for many Government departments, such as the Post Office, the Stationery Office, Trinity House and the War Office, however interesting to the citizen and taxpayer, does not specially concern the medical man and the sanitarian; it is in the matter of food and drugs that these most find interest. The examination of tea discloses a considerable percentage of packages as "unfit for consumption as food," and it is satisfactory to know that ample precautions are taken to prevent this from finding its way into the market. The Report makes plain the fact that the practice of adulteration does not prevail to any marked extent in the retail liquor traffic. The number of samples of beer adulterated,

or even watered, is really insignificant, whilst spirits, particularly whisky, were found almost universally free from added deleterious ingredients, although samples were taken from public houses, Irish fairs, and other such places where suspicion might most reasonably be excited. A year or two ago the danger to drinkers owing to the presence in beer of glucose adulterated with arsenic was fully exposed. It is satisfactory to be assured by Dr. Thorpe's Report that this danger has now virtually ceased to exist. Out of fifty-five samples analysed only thirty were found to contain arsenic in excess of the hundredth of a grain per pound. This was the quantity named as a limit in the Royal Commission on Arsenical Poisoning, upon whose Report we commented soon after its appearance a year or so ago.

### PERSONAL.

THE name of Dr. E. Arthur Dando has been placed on the Commission of the Peace for the Borough of Dudley.

LIEUT.-COLONEL R. J. S. SIMPSON, Royal Army Medical Corps, has taken up his duties as Medical Officer for the London District.

DR. ADAM WRIGHT, of Toronto, has been elected President of the Dominion of Canada Medical Association.

WE regret to record the death of Mr. S. G. Lushington, who has been for some years legal assessor to the General Medical Council.

LORD CROMER has been appointed by the Secretary of State for the Colonies to be Chairman of the New African Entomological Research Committee.

PROFESSOR WALKHOFF, Professor of Dental Surgery in the University of Munich, was president of the Fifth International Dental Congress, held in Berlin last week.

AT Winnipeg, on August 25th, Sir J. J. Thomson, F.R.S., was installed as president of the British Association for the Advancement of Science, in succession to Dr. Francis Darwin.

SIR HENRY BURDETT has started on a tour of inspection of the principal English Hospitals this week. Having been actively engaged in hospital work for upwards of forty years, his present effort possesses special interest and importance.

DR. R. A. PRICHARD, of Conway, North Wales, who has filled the office of Mayor of Conway six times, was last week presented with a Sunbeam 14-18-horse power motor landaulette, as a mark of the esteem in which he is held both professionally and by the public in the district in which he has long resided.

A FATAL accident occurred last Thursday at Sparkhill, Birmingham, whereby Dr. Dalrymple, who was at the time acting as *locum tenens* for Dr. Tipping, was killed in a tramway collision. The victim of this unfortunate mishap was about 25 years of age, and had only recently qualified.

SIR ALFRED JONES, K.C.M.G., Chairman of the Liverpool School of Tropical Medicine, with a view to extending the scope of the school, and of bringing it into still closer practical touch with the Tropics, has decided to appoint a medical officer to carry out the study of tropical medicine at Las Palmas, Grand Canary.

# A CLINICAL LECTURE

## ON

### FEEBLE-MINDED CHILDREN. (a)

By A. F. TREDGOLD, L.R.C.P.Lond., M.R.C.S.Eng.,

Medical Expert to the Royal Commission on the Feeble-Minded; Consulting Physician to the National Association for the Feeble-Minded, &c., &c.

#### PART II.

WE now come to the clinical features of these children, and I will first of all describe cases of primary feeble-mindedness. As I have remarked, these are by far the most numerous, and probably eight or nine-tenths of all feeble-minded children met with in practice fall within this group.

These children differ very much in the degree of their deficiency. The lower members of the class are with difficulty separated from the imbeciles. The higher members, on the other hand, are in some ways but little removed from the dull and backward of the normal population. It is clear, therefore, that no general description can be given which will be applicable to every feeble-minded child, but I will endeavour to place before you the chief characteristics of the class.

With regard to their physical condition, a small number might fairly pass as normal, but such cases are exceptional, and the majority present unmistakable anomalies of bodily structure or function, as well as of mental development. Bearing in mind that their condition is the result of a germinal imperfection, this, of course, is what we might expect.

Anatomical anomalies, or so-called stigmata of degeneracy, are usually neither so plentiful nor so pronounced in the feeble-minded child as in the imbecile or idiot; nevertheless, they occur in over 90 per cent. of these cases, and in nearly a quarter of the cases these defects are triple.

One of the commonest anomalies concerns the cranium, which is either abnormal in shape or size, being bossed, ridged, or asymmetrical in fully half of these children. Between the ages of seven and ten years, the maximum circumference is generally about half-an-inch less than that of a normal child of corresponding age and sex, but as time goes on this discrepancy becomes more and more marked, and by the 14th or 16th year the difference is often as much as an inch. Next in frequency to the cranium we find anomalies of the palate, and then malformations of the external ear and eye.

Inquiries will nearly always show that in these children, dentition, standing, walking, and talking have been abnormally late. It may be 4, 5, or even 6 years before the child says a word. This retardation continues with advance in years, so that at every period of its school life the mentally defective child compares unfavourably in its bodily growth and acquirements with the one of normal intellect. Further, the bodily functions are often imperfectly performed, the circulation is feeble, so that chilblains and sores are frequent in cold weather; assimilation is defective, so that the child remains thin and ill-nourished; the vitality generally is diminished, and catarrhs and ill-health are exceedingly common. Feeble-minded children average 2 to 4 in. less in height, and from 3 to 12 lb. less in weight, than normal children.

Another frequent characteristic of these children is seen in various anomalies of nerve action. In some there is a marked diminution of activity, and they are heavy, stolid, and laboured in all their movements. In others the reverse is the case, and all movement is in excess. These latter cannot sit or stand still, they are distracted from their task by every little thing around them, and they are often full of tricks and habits. Co-ordination of movement is slowly and laboriously acquired, and the making of pothooks and

hangers presents difficulties unknown to the ordinary child.

Speech is not only late in making its appearance, it is also defective in fully one-third of these children. It may be remarked that inability to pronounce, not one particular, but many consonants, is very commonly indicative of mental deficiency.

With regard to their mental condition: Sensory defects are not a prominent feature of the feeble-minded degree of amentia. Defects of hearing (which are generally due to disease of the middle ear) occur in about 8 per cent., and defects of vision in about 15 per cent. of cases. Colour blindness, although in many cases seemingly present, is not in reality any more common than in normal children.

Active or voluntary attention is commonly defective, and the most trifling thing serves to distract these pupils from their occupation, so that, even where the attention is readily gained, it is with difficulty held.

Memory is often said to be defective, but I think that in many cases this arises from a defective comprehension. In the tenacity of the memory for things which are really understood, I doubt whether feeble-minded are much, if any, inferior to normal children. As a class they are imitators rather than originators; they are defective in control, and action is more often the result of sudden desires and impulses than of any deliberate purpose. They are capable of the simple feelings of pleasure, pain, fear, astonishment, anger, surprise, and the like, but their emotions are usually weak and evanescent.

All of them are lacking in the logical, and most of them in the æsthetic, sense. In a small proportion there is also a marked deficiency or perversion of the moral sense, and such will lie, pilfer, and generally misconduct themselves without the slightest compunction. Some of them are exceedingly cunning, and a few are guilty of acts of marked cruelty to other children or to dumb animals. Others will make utterly unfounded accusations with such an amount of detail and appearance of truth that the unwary may easily be deceived. On the other hand, there are many who are quite well-behaved, obedient, and contented, and who even possess a tolerable conception of their moral and religious obligations.

So far we have been concerned with the primary group of feeble-mindedness, in which the defect is due to germinal imperfections. It is now necessary to consider that much smaller but very important group of cases of secondary amentia, in which the growth of the brain has been arrested by some external influence. These external factors are many and varied, and I think they are most conveniently considered at the three periods of before, during, and after birth.

The cause which brings about arrest of cerebral development whilst the child is still within the uterus is usually a circulating toxine, such as lead or alcohol. Occasionally, however, starvation or severe ill-health of the mother during the child-bearing period may apparently lead to the same result. It has also been suggested that ebolics may act in a similar way, but of this I have no experience, and, as a matter of fact, in my opinion the number of cases of feeble-mindedness which are the result of causes acting upon the foetus is exceedingly small. Maternal impressions are often put forward as causes by the parents, but I must confess that I have never seen a case where such an allegation would bear investigation.

Feeble-mindedness may occasionally arise from

(a) Delivered at the Medical Graduates' College, July 7th, 1909.

injury inflicted upon the brain during birth, and this injury is usually the result of asphyxia or destruction of cortical tissue by hæmorrhage. I have never seen a case of mental defect caused by the forceps, and, although I know some authors maintain the contrary view, I doubt whether feeble-mindedness has ever resulted from the proper application of these instruments.

Cases which owe their origin to labour are not very numerous, but they form a fairly characteristic class, and it is very important for the practitioner to remember that mental defect may arise in this way.

Thirdly, after birth, feeble-mindedness may be the consequence of a localised arrest of cortical development which has been caused by disease. This disease may be one of the ordinary acute infections, such as scarlet fever, measles, diphtheria, or whooping-cough, or it may be a special condition to which I will allude in a moment.

For purposes of description we may divide these secondary cases of feeble-mindedness into two groups, which we may call the vascular and toxic.

The best example of the vascular group is seen in those cases which are due to injury during birth, and the clinical picture is usually like this:—

In the first place, there is generally a well-marked history of asphyxia, or some comatose condition, from which the child was with great difficulty revived. But he remains torpid, and his respiration is apt to be slow and irregular, and his pulse feeble. The pupils may be contracted, and the anterior fontanelle is often tense. He does not cry, and evinces little interest in the breast. In a few days convulsions usually make their appearance, but in between these the muscles may remain rigid, and opisthotonos may even be present. At a somewhat later period paralysis may be noticed. Sitting up, walking, and first attempts at speech are all delayed, and after a time it is seen that the child's behaviour is not quite the same as other children. Sometimes mental deficiency is not noticed until schooling is begun, when the child is found to be incapable of any mental effort.

There can be no doubt that a large proportion of such children die in the early years of life, but others thrive and live for many years, and it is these who come under notice on account of their mental condition. The chief features are more or less defect of mind, with usually some paralysis and imperfect development of the lower limbs. Stigmata of degeneracy are absent, and these children, as well as those of the next group, are usually quite devoid of the unpleasing and even repulsive appearance of those suffering from primary mental deficiency.

In the toxic group the cause may be, as I have stated, almost any one of the acute infectious diseases of childhood, and the involvement of the brain is either by a general toxæmia or by extension of a septic process from the ear or nose. More commonly, however, feeble-mindedness after birth is due to a specific poisoning of the cortical cells, a condition which was first described by Strümpell, and which is known as poli-encephalitis acuta. The process is probably very similar to the poisoning of the anterior horn cells which occurs in anterior polio-myelitis. I have seen several cases of this nature, and they are very commonly mistaken for sunstroke or meningitis.

The first indication of such an affection of the brain is often malaise or vomiting, and this is followed by restless delirium or unconsciousness, fever, convulsions, and often paralysis. The temperature rarely rises to more than 102° F. Paralysis may be noticed at the outset, or it may not appear until a few days afterwards, and in some cases it is absent entirely. The reflexes are increased, but there is rarely any marked disturbance of sensation. In course of time the fever abates, the convulsions cease, or continue only at rare intervals, the child recovers consciousness, and some amount of improvement takes place in the paralysis. But the psychic functions have been damaged; in some cases an obvious impairment of the intellect is noticed immediately, in others only as the child begins to get about and mix with his companions. If he had begun to speak, he may now be

speechless. The playmates and games of which he was formerly fond now cease to attract him, and, in short, there is a marked alteration in his whole disposition and behaviour. As time passes it is found that his capacity for learning has been interfered with, and it is soon evident that the illness has resulted in a more or less serious arrest of mental development.

In view of the widely different ultimate effects of these cerebral lesions, it is obvious that no accurate forecast is possible. It is probably only a minority of the children so affected who become aments, but this possibility can never with certainty be excluded until the lapse of some time after the illness. Paralysis affords a very uncertain guide, for there may be extensive hemiplegia with no intellectual defect, and there may be profound amentia with but trifling or even no paralysis at all. And even if one could definitely exclude all involvement of the psychic areas, there would still be the possibility of recurrent epilepsy, with the consequent induction of amentia.

Such, gentlemen, are the chief characteristics of feeble-minded children. Here, however, let me emphasise the fact that they differ amongst themselves just as much as do ordinary children. Not only do they vary greatly in the degree of their intelligence, but also in their habits, temperament, and general disposition. In fact, they possess an individuality, and methods of treatment and training, to be successful, must be based upon a study of each particular child.

But, whatever the particular features may be, there is one quality which characterises all the varieties and grades of these children, and that is their inability to swim against the stream, or even to keep their heads above water without the assistance of some kindly hand. Whilst the ordinary child of 14 or 16 years has not only a considerable knowledge of common things and events, but has, in addition, acquired notions of qualities and conceptions of the abstract; whilst he has developed the faculty of comparing, relating, and judging between these conceptions, and of tracing a connection between cause and effect; whilst his mind is now sufficiently developed to enable him to shape a definite course in accordance with an ideal—the feeble-minded child of similar age is still happy with his toys, and his whole behaviour and conversation still indicate the infantile and imperfect character of his mind. Bodily and mentally he is always in arrears, and with each advancing year his intellect is left further and further behind that of his more fortunate fellow.

We must now briefly consider the question of diagnosis.

As you are well aware, there are some diseases which, if we only give them time, diagnose themselves. Unfortunately, however, when this time is arrived at, the patient has often passed beyond the possibility of medical aid. This is the case with feeble-mindedness. Do not, let me beseech you, content yourselves or try to content the child's parents by saying that he will "grow out of it," or that "he will be all right when he is 7," or "14," or "21."

By so doing we are neglecting training at the only period when it is likely to be of any use, and we are almost certainly driving the child into the hands of unscrupulous practitioners or quacks. I have known scores of pounds spent upon the performance of useless operations, drugs, and all sorts of magnetic and galvanic appliances, whilst systematic training, the only thing which could do the child any real good, was absolutely neglected. The result is that the child grows up, not only much more defective than he need be, but the possessor of habits and propensities which are a lifelong trouble and anxiety to all about him.

In these cases early training is essential, and therefore a diagnosis at the earliest possible moment is of prime importance.

Now, the diagnosis of idiocy and imbecility is easy, but the diagnosis of the milder defect—feeble-mindedness—may be a matter of considerable difficulty. Much skill and knowledge are required, which can only be obtained by close observation of the class; but I will try to place before you the chief points to be considered.

First of all, it is necessary to avoid the fallacy that

feeble-mindedness is merely a falling short of the normal. I have known several medical inspectors of school children to set up what they call a normal standard of intelligence, and then to class as defective all those who fell short of it. The result of this is that many children are stigmatised as defective who are not so at all. Feeble-mindedness is this, certainly, but it is something more; it is the result of a definite cerebral lesion, of an imperfect or arrested development of cortical cells, and the diagnosis must depend upon finding evidence of this defect.

When, therefore, the physician is consulted with regard to a child, in whom, by reason of mental dulness or inability to progress in school, the suspicion of mental defect arises, he must make a careful examination of each psychological function, and, having discovered a definite mental flaw, he must consider whether this is of such a nature as to account for the dulness and to lead to some permanent mental incapacity.

To enter at any length into this subject would take us too far into the intricacies of psychology, but I may say that careful examination of the feeble-minded child will generally reveal some lessened range or acuity of perception, some paucity of association or memory, some defect of voluntary attention, or of ideation, or of the judgment and will. Such an examination is, perhaps, not at first easy, but with a little care and patience it soon becomes so.

There are two other points which are of material assistance in the matter of diagnosis—firstly, the family history, and, secondly, the personal history.

With regard to the family history, morbid heredity occurs in such a large proportion of these cases that if, in a child of sub-normal intelligence, we find a strongly marked psychopathic taint, the probability of mental defect is greatly increased. On the other hand, a clean and good family history is of value as indicating rather that the mental dulness may be the result of some temporary condition or physical disease.

Secondly, the previous personal history often affords most valuable information. In cases of primary amnesia it will nearly always be found that a general retardation of development, with mental dulness or marked peculiarity, has been present from soon after birth. In infants with a psychopathic heredity, marked and persistent restlessness, which cannot be accounted for by bodily ill-health, is a very suspicious symptom. So also is abnormal placidity and indifference to surroundings, although the mother is apt to look upon this as merely an excessive amount of goodness.

With regard to the time at which the child cuts its teeth, or first sits up, or walks, or talks, it is, of course, obvious that delay in any one of these things is of little importance, for the range of normal variation is very considerable, but delay in several of them, provided there is an absence of bodily disease such as rickets, must be regarded as very suspicious.

In secondary amnesia, on the other hand, inquiries will nearly always reveal a clear history of some serious toxic or vascular lesion of the brain or of epilepsy, previous to which the child's condition has been normal.

Finally, it is necessary that I should say a few words with regard to some conditions which so closely simulate feeble-mindedness that they are often mistaken for this condition.

Perhaps the commonest mistake is with regard to children who are merely dull and backward. These are found in all schools, and vary from 5 to 20 per cent. of the children in attendance. It is sometimes very difficult to distinguish them, but I think that attention to the points I have just mentioned will generally prevent a mistake.

Next, there is another group of children whose development is not arrested, but merely delayed. Usually these are the result of insufficient or improper feeding and general home neglect, and if the conditions are known to exist, the examiner will be wise to withhold a definite diagnosis until the child's general condition has been improved by suitable treatment.

Another point which it is important to remember is that defects of vision, hearing, speech, or serious constitutional disease often make a child dull and stupid, and cause him to appear defective. I have had boys and girls produced by school teachers as cases of feeble-mindedness who merely wanted the attention of the oculist or nose and throat specialist, and I have seen a boy returned as defective who was mentally sound, but suffering from pulmonary tuberculosis.

Finally, nervous exhaustion due to overwork, epilepsy, and even insanity, may all be confused with feeble-mindedness, and these conditions, as well as the physical disorders which I have just mentioned, must be excluded before a diagnosis can be made.

There are many other points with regard to feeble-minded children to which I might allude, but time does not permit, and I think I have mentioned all those of importance. I can only hope that this brief account of a somewhat intricate subject may be of some use to you in daily practice.

## ORIGINAL PAPERS.

### A CHAT ABOUT

## ANTIGENS, ANTIBODIES AND THE FIXATION REACTION OR DEVIATION OF THE COMPLEMENT.

### BASED ON NOTES

By PROFESSOR CHANTEMESSE, M.D.,

Of the Faculty of Medicine of Paris.

[ESPECIALLY ADAPTED FOR THE MEDICAL PRESS  
AND CIRCULAR BY F. HELME, M.D.]

RECENT advances in our knowledge of the defensive action of the blood and humours have led to the introduction of many terms which are necessarily unfamiliar to practitioners at large, so that it may not be inopportune to endeavour to explain in an informal manner in what these theories consist. These theories are independent of phagocytosis, they bear, indeed on an entirely different defensive apparatus, one, too, that is singularly difficult to explain.

The phenomena in question are simple enough, it is the terminology that renders them unintelligible. The actual nature of the active constituents of serum being unknown each observer looks at them from his own point of view, and deals with them accordingly, giving rise, inevitably, to confusion worse confounded—a confusion which will only be dissipated when the theories have had time to "shake down." Meanwhile, if we wish to keep abreast of the movement, there is nothing for it but to try and understand these terms.

A foreign substance that penetrates the organism and gives rise to reactionary phenomena used to be called a virus. This term, however, is not comprehensive enough, so that it became necessary to make use of such complementary terms as toxins, etc. This did not give rise to much trouble, because everyone is familiar with the meaning of these terms; but every substance, whatever its nature, introduced into the blood, provokes a defensive reaction, whether it be a micro-organism or its secretions, a chemical substance or a virus, a blood corpuscle just as well as a microbe. A word was, therefore, required which should comprise all these bodies without prejudging their nature, so the word *antigen* was created. Antigen is synonymous with virus, microbe, etc., over which it has the advantage of being more comprehensive, less

-specific so to speak. Then, too, and this is important to bear in mind, it implies the formation in the humours, after inoculation, of special agents of defence, the latter being termed *antibodies*.

Since the antigen, when introduced into the blood of man, gives rise to the production of an antibody, it is necessary for us to ascertain what the latter is. Now the antibody is like the little scholar's definition of a point, *viz.*: something that does not exist. Well, it does exist, but only to the eye of reason, for it has never been seen or handled. All we can say is that it is formed by the blood for the defence of the organism and that it consists of two bodies—as is shown by the action of heat. One of these two bodies is thermolabile, *i.e.*, is destroyed by a temperature of  $55^{\circ}\text{C}$ ., so that it can easily be got rid of by heating the serum or the liquid containing the substance with the antibody. This particular substance is called *alexine*—a word to be remembered. It is not specific, that is to say, it is present in the serum of every animal, healthy or diseased. It is also sometimes called the *complement* because it supplements or completes the action of the second body which is the *sensitiser*.

The sensitiser is thermostabile, it resists a temperature of  $55^{\circ}\text{C}$ ., and is only destroyed by temperatures above  $75^{\circ}\text{C}$ . Unfortunately, this body is known under several different names, and this is what makes the question so difficult to understand; it is called, for instance, agglutinine, precipitine, sensitiser, or amboceptor. The two words to be particularly borne in mind are *sensitiser* and *amboceptor*. The former, introduced by Bordet, is of Belgian origin, the latter, imagined by Ehrlich, is of German origin.

In short, antigen gives rise to antibodies within the organism, and the latter are made up of two parts which can be distinguished one from the other by their reaction to heat; one, non-specific, common to every serum, is killed at  $55^{\circ}\text{C}$ ., this is *alexine* or the *complement*; the other, more robust, resists a temperature of  $55^{\circ}$ . This is frankly specific, that is to say, it is peculiar to the individual antigen, it only acts upon one cell, one particular microbe, a blood corpuscle of a given species, to the exclusion of all others. This substance, the so-called sensitiser, is also known as *amboceptor* and *agglutinine*, though the latter term, while currently employed, is possessed of less importance.

It may be objected that these are all highly technical details, quite devoid of interest to the general practitioner, but this is not so. Let us assume that you have a patient whom you suspect of having had syphilis, although there is nothing in his personal history or in the objective signs to confirm that suspicion and justify your instituting the anti-syphilitic treatment. Well, thanks to the reactions of the sensitiser and the alexine, you will be enabled to demonstrate the existence of the syphilitic taint with mathematical certainty. This reaction is called the *fixation test* or the *deviation of the complement* (also known as Wassermann's test from the name of the discoverer). We will now explain this test.

Proceeding in accordance with the data given above, let us institute a preliminary conclusive test. A guinea-pig is inoculated several times over with thoroughly defibrinated red corpuscles of the rabbit (a different species to the guinea-

pig). The blood of the guinea-pig brought face to face with the invader forthwith sets to work to organise its defence by producing an antibody, the rabbit corpuscles having in this case acted the part of an antigen. So far everything is clear enough.

But it has been pointed out that the antibody consists of two substances, one, alexine, common to every serum; the other, specific, the sensitiser. Now, every time the sensitised guinea-pig blood is brought into contact with rabbit's blood, even *in vitro*, hæmolysis takes place with breaking up of the rabbit corpuscles. This phenomenon is due to the following mechanism—a mere hypothesis it is true, but one which concords with the facts.

Of the two substances contained in the antibody one, the sensitiser, acts the part of a mordant; it impregnates the rabbit corpuscles which are thus rendered mordant, and become amenable to the complementary action of the alexine or complement. Ehrlich applied the term amboceptor to the sensitiser, because it serves as a bridge, as a point of contact, between the corpuscle on the one hand and the alexine on the other. A glance at the accompanying diagram will make it easy to understand the employment of the word amboceptor.

FIG. I.

The point to be remembered in this experiment is, that if we wish to act upon any invader: microbe, virus, corpuscles, described generically by the word antigen, the antibody requires both its constituent parts. The sensitiser, likened to a mordant, and the alexine, which completes the work of the former. *But one cannot act without the other.*

Having grasped this much we will now discuss the steps to apply Wassermann's test, that is to say, to ascertain by simple inspection of the patient's blood whether or not he is syphilitic. (1) Since the treponeme, the infective agent of syphilis, has not so far been obtained in pure culture we take a piece of liver from a newly-born syphilitic infant, a supply of which is to be had in every laboratory. This is pounded and mixed in tube A, with a little sterilised water. This bit of liver is merely a *milieu* rich in treponemes.

(2) In tube B we place a small quantity of the serum from the patient supposed to be syphilitic. If this be the case the serum will contain both a sensitiser peculiar to the treponeme and an ordinary alexine; in the contrary event *only alexine will be present*.

(3) In a third tube C is some guinea-pig serum, sensitised (or immunised), as already explained, against rabbit blood. This, however, is heated to  $55^{\circ}\text{C}$ ., in order to destroy the alexine so that the sensitiser alone remains.

(4) Lastly, in a fourth tube D are put the

thoroughly washed defibrinated corpuscles from the rabbit blood.

We now mix the contents of tubes A and B, then adding the contents of tubes C and D,

FIG. II.

FIG. II.—The patient being syphilitic his serum, containing a complete antibody (alexine and sensitiser), attacks the treponemes in the syphilitic infant's liver, and nothing happens in tubes C and D.

placing the mixture in the warm chamber for two hours. If there be syphilis it will be seen that the rabbit corpuscles remain intact and this amounts to negative result from the point of view of the experiment since no change has taken place in the liquid, but it is a positive result from a diagnostic point of view. *i.e.*, the patient is certainly syphilitic.

Now what has taken place? Simply this, that the patient's blood having been sensitised to the treponeme (by his infection), the antibody attacks it, the sensitiser performs its duty as a mordant, the alexine completes the task and we get treponemolysis, a breaking up of the treponemes. The corpuscles in tube D have not been attacked by the serum of tube C because the latter only contained the sensitiser without alexine, and, as has been pointed out, these two bodies can only act in conjunction.

We will now assume that the patient is not syphilitic. Returning to the four tubes I mix as before the contents of tube A, containing the treponeme liver, with that of tube B, containing the patient's serum. To this mixture I further add the contents of tubes C and D, the latter containing the washed red rabbit corpuscles, the other the guinea-pig serum deprived of its alexine by heat. The whole is placed in the warm chamber for two hours whereupon, in opposition to what took place at the other test, the liquid becomes red and turbid. What then has happened on this occasion?

The patient not being under the empire of syphilis his blood has no action on the treponeme. But although this blood contains no antibody properly so-called, it nevertheless contains alexine, which is common to all serums. Now the latter remains free to act since it is not taken up with the treponeme, so it goes to complete the action of the sensitiser contained in tube C. The two substances being thus combined act the part of a complete antibody towards the corpuscles of rabbit, so there is hæmolysis instead of treponemolysis as on the previous occasion. In other words, the sensitiser has caused the alexine complement free in the patient's blood to deviate, it has *fixed* this complement alexine in the rabbit corpuscles, whence the terms fixation test, deviation of the complement, employed in describing Wassermann's test.

If, instead of the treponeme, I had made use of any other pathogenic microbe, the typhoid bacillus for instance, the reaction would have taken place just in the same way.

Going a step further Drs. Levaditi and Auguste Marie of Villejuif have endeavoured to make use of cerebro-spinal fluid instead of serum. It occurred to them that possibly Wassermann's reaction might answer the purpose of demonstrating the syphilitic origin of general paralysis of the insane. Having put this to the test they found

FIG. III.

FIG. III.—The patient is not syphilitic. The natural alexine of the patient's serum is left free. It is deviated to the sensitiser of tube C, deprived of alexine by heating to 55° C. When this adjunction takes place the antibody, thus completed, has attacked the rabbit corpuscles and hæmolysis, visible to the naked eye, results. To simplify matters, since it is only a diagram, the corpuscles are left intact, though in reality they have been broken up.

that the reaction was the more obvious the more advanced was the specific lesion. We all know

that there are cases in which mercury appears to improve matters, while in others it aggravates them. How are we to know whether the mercurial treatment has not in some way hindered in the latter the action of the antibody then in course of formation, consequently are we not entitled to hope that this reaction when simplified and improved may provide us with a sure and safe guide to the desirability of the treatment?

I will stop here. I have done my best to make this subject clear to my readers, and am satisfied that my narrative will be found less tedious to read than it was to write.

### VISCERAL SYPHILIS. (a)

By W. B. WARRINGTON, M.D., F.R.C.P.Lond.,  
Physician to the Northern Hospital; Lecturer and Examiner in  
Clinical Medicine in the University of Liverpool.

THE late Dr. Hilton Fagge, in his great work on medicine, says that three diseases are often missed—phthisis, scabies and syphilis; phthisis because it is not looked for, scabies because it is overlooked, and syphilis because it is forgotten. Mr. Hutchinson, in a recent address on syphilis, said he considered that the disease was both less frequent and less severe than formerly. We shall probably all agree that it is less severe, but it may well be questioned whether it is less frequent. Mr. Hutchinson takes an optimistic view of the value of treatment, and maintains that syphilis is a disease which is strictly curable. Sir Wm. Gowers, dealing perhaps more specifically with later effects, regards the doctrine of the curability of syphilis with some suspicion. Certainly, nothing tends more to support the view than the mysterious way in which tabes and general paralysis sometimes appear—diseases which, constantly accumulating evidence tends to show, have as an almost constant antecedent a history of syphilis. Syphilis, thus, is readily forgotten by the patient. The chancre may disappear and leave no trace. On the authority of Mr. Hutchinson, we may even say that in certain cases it does not form at all; the ordinary secondary signs may be slight, or even absent; and the activity of the virus, working in unobserved secrecy, may only be revealed by the appearance of visceral symptoms. Sir Wm. Gowers would almost lead one to accept as a rule that certainty of absence of exposure to contamination is the only assurance one should accept from a patient. I shall relate some cases to you which show how much more reliance we ought to place upon the certain facts of pathology than upon the patient's or on even our own disposition to believe that syphilis can be excluded.

I have ventured upon these introductory remarks because experience has taught me how valuable is the *obiter dictum* of Dr. Fagge. Syphilis, undoubtedly, is most frequently met with in the central nervous system; probably next, its effects are manifested in the diseases of the great thoracic blood-vessels, the aortic valves, and the heart. Of the abdominal viscera, the liver is the organ in which the disease assumes great clinical importance, whilst syphilis of the respiratory system, excluding the larynx, is extremely rare. I shall ask your kind attention only to such aspects of this large subject as are familiar to me from personal experience, and only touch upon rarer manifestations of the disease.

*Syphilis of the Abdominal Viscera.*—I find that, of my last 1,000 hospital cases, 30 suffered from gross disease of the liver, cancer, cirrhosis, and perihepatitis chiefly, and that they include 4 cases which were certainly known to be syphilitic. The disease is not, therefore, very frequent, but the importance of a correct differential diagnosis is great, for if the specific new formed cellular tissue has not been replaced by fibrous tissue a complete cure may be obtained. Lardaceous disease, the result of syphilis, is now much

rarer than it used to be; and the presence of associated symptoms indicating a similar disease in the kidneys, spleen, or intestines will make the diagnosis easy. It is from the three diseases I have just mentioned that the diagnosis has chiefly to be made. One of my cases resembled malignant disease in so many ways that the real state of affairs was unfortunately not suspected. A woman, æt. 56, had for nine months complained of severe abdominal pain and tenderness on the left hypochondriac region. She was obviously ill, though not particularly cachectic. On examination of the belly, an ill-defined swelling was felt in the left flank and the liver was just palpable. There was no jaundice and no ascites. The bowels were most constipated; but, under repeated enemata, the pain disappeared, and the swelling in the left of the abdomen greatly diminished.

The patient now left the hospital, but returned in a few months, greatly changed for the worse. She looked very ill and cachectic, the abdominal pain had increased greatly, and also now radiated down the left thigh. A distinct hard mass could be felt in the left hypochondrium, and the liver was large, perhaps the left lobe more than the right; there was moderate ascites, which was three times removed; jaundice was still absent. Here the age and sex of the patient, her general appearance, the violent pains and the abdominal tumours, seemed to be a typical picture of cancer, and no specific treatment was adopted.

The *post-mortem* showed that the liver had the characteristic irregular shape due to gummatous formation, the right lobe was small, contracted by the cicatrices of a gumma, the left enlarged, and showed a large gumma at its juncture with the right lobe; there was also an enlarged spleen, and some chronic perihepatitis and perisplenitis. I now think I failed to lay proper stress upon the following points:—The liver in cancer is usually very large; new growths cause the largest of liver swellings, in syphilis there is often a peculiar one-lobed enlargement; jaundice is hardly ever a symptom of syphilis; it is present in 50 per cent. of cancer cases. The duration of cancer, when once the liver is found to be large, is very short; in none of my cases has the patient survived over eight months. In syphilis the liver tumour may exist for many months. Definite, knobby, umbilicated masses felt on the rapidly enlarging liver are amongst the strongest facts indicating the real malignant nature of the disease.

Two other cases successfully treated resembled portal cirrhosis or simple chronic peritonitis with perihepatitis. In one the ascites was serous, in the other chyliform. Apart from the history or presence of other syphilitic signs, important points are, the absence of a history of alcohol and dyspepsia, the fairly healthy appearance of the patients, the absence and wasting and toxæmia of hæmorrhages or jaundice, and of a large spleen, which, in progressive cirrhosis at least, is almost a constant occurrence. Chronic perihepatitis is, in addition to other signs, characterised by a constant recurrent ascites, not observed in syphilis of the liver. In the fourth case, the patient, under the care of my colleague, Dr. Bushby, was a sailor, æt. 35, who had suffered from dysentery two and a quarter years ago. On admission, he was obviously very ill with irregular fever, marked anæmia, and a leucocytosis as high as 27,000. The liver projected well below the costal margin, the lower edge was felt firm and distinct. On the right lobe in the anterior axillary line was a smooth, round projection, painful on pressure, and semi-fluctuant. I hope you will agree with me that the proper diagnosis was tropical abscess. Mr. Monsarrat, however, on opening the abdomen, disclosed a tumour-like mass, having the appearance of a gumma. Subsequent treatment with iodide completely cured this patient, and there can be no doubt that the patient suffered from syphilis of the liver. Cases similar to this are recognised; and, so far as my knowledge helps me, I fear I can only class this particular example as one of those instances in which the reasoning was legitimate, but the conclusion incorrect. Of course

(a) Paper read before the St. Helen's Medical Society.

the history of dysentery and high leucocytosis were important facts which could not be ignored.

To summarise: Syphilis should always be thought of; the disease is often curable; it resembles chiefly common cirrhosis and perihepatitis, but may closely simulate cancer and hepatic suppuration.

A condition we often meet is the splenomegaly of infancy. The common causes are syphilis, rickets, and gastro-intestinal disturbances, without evidence of either syphilis or rickets. The infant may or may not be anæmic, the spleen and often the liver can be felt a few finger-breadths below the costal margin. The important question is the cause and prognosis. The following are, I think, the chief points in diagnosis. If the enlarged spleen is found in a child during the first six months there is strong suspicion of syphilis; the rickety spleen is chiefly met with from the ages of twelve months to two years. Snuffles, to be evidence of syphilis, must be of long duration. Many children have a simple coryza; occasionally, congenital adenoids may also produce a coryza. Craniotabes, i.e., a thinning of the parietal bones, Parrot's nodes, or cranial osteophytes, chiefly occur on the frontal bones, and are strong evidence of syphilis, as also, of course, is any periosteal thickening of the shafts of the bones. This enlargement of the spleen is a toxic condition, and in syphilis, unlike rickets, it is to some extent a measure of the cachexia. The enlargement of the spleen itself does not imply a bad prognosis. Many of the cases gradually improve and the spleen diminishes in size, as is conclusively shown by the fact that in the later years of childhood the proportion of cases of splenomegaly is not nearly so numerous as in earlier life. The prognosis is to be found in the condition of the blood: a great reduction in the amount of hæmoglobin and of the number of new cells, especially changes in size and form, is serious, and so also is considerable leucocytosis.

Another interesting condition is the syphilitic nephritis. Whilst syphilis is probably a factor in the causation of chronic renal disease, a true syphilitic nephritis may be recognised as occurring in the first two years after infection. Rose Bradford lays stress on the presence of large amounts of albumin, but no diminution in the amount of urine, the absence of casts, and often the absence of dropsy. This form has been chiefly studied by French physicians, and all agree that great benefit follows mercurial treatment. In concluding this sketch on syphilis of the abdominal viscera, I may venture to recall the statement of Osler, that the diagnosis in a number of cases is missed because the testicles are not examined.

*Syphilis of the Vascular System.*—It is remarkable that whilst the small arteries in the central nervous system so constantly show, as the result of syphilitic disease, the characteristic endarteritis, in other parts of the body it is the largest blood-vessel, the aorta, its main branches, and the coronaries, which chiefly suffer; syphilitic endarteritis of the smaller blood-vessels is very rare. The diagnosis and effects of syphilis in some of these instances are perfectly plain. The majority of aneurysms occur in those who have acquired the disease. Of 7 recent cases, 4 had undoubtedly been infected, and the disease could not be excluded in the remaining 3. Muscular strain, with its increase of blood-pressure, often occurring suddenly, is the primary cause, acting on blood-vessels already undergoing atheromatous degeneration. Not infrequently the coronaries are affected with a true syphilitic endarteritis, leading to grave changes in the heart, myocardial degeneration, perhaps associated with an actual gumma or its fibrous transformation. The change is one of the causes of sudden death which may result even when no symptoms have previously existed. The diagnosis is naturally very difficult, and is largely the result of a process of exclusion, and an appreciation of the known pathological effects of syphilis.

An acute myocarditis arises in connection with acute infective disease, especially diphtheria, typhoid,

influenza, pneumonia, rheumatism, and septic infections: it is, as we know, very dangerous, and may leave behind chronic insidious degenerative changes in the cardiac muscle. The patients complain of feeling tired, of dyspnoea on exertion, and of oppression in the chest; later, the symptoms of insufficient cardiac action become manifest, the pulse becomes quick, irregular, and unequal, the first sound at the apex, impure, and at the base often an accentuated aortic sound is heard. Now, unless the history guides us, it is impossible to distinguish clinically whether the case is the result of a previous acute myocarditis, or the result of disordered nervous mechanism, of alcohol, syphilis, or arterio-sclerosis, with degeneration of the coronaries or renal disease. If, however, a youngish man, with no valvular lesion, no history of rheumatism, and in whom the causal factors I have mentioned can be excluded, suffers from symptoms of cardiac failure, syphilis should be thought of.

Again, when a patient presents himself with a large heart, but healthy radial arteries and no renal disease or adherent pericarditis, but perhaps evidence of aortic disease, as indicated by the characters of the second sound and slight impaired resonance over the first bone and manubrium sterni, syphilis is to be thought of. The treatment is difficult: the digitalis group, unless there be actual failure of the right heart, with dropsy and its accompanying symptoms, does little good, and should only be given in small doses. Dr. West has pointed out that digitalis in degenerative cardiac muscle has a peculiar cumulative action; the heart beats are easily reduced from 150 to 120 or 100, and then perhaps suddenly drop to 50 or 40. Administration beyond this point is dangerous. This is an effect of digitalis in cardiac degeneration I have often observed, and I think the drug in such cases must be closely watched. Strychnine is a better cardiac and nerve tonic. The general metabolism of the body may be improved by small doses of calomel, and the peripheral field of resistance regulated by the nitrites with iodide and potash.

One other statement may, I think, be made. Aortic valvular disease without affections of the mitral valve is very rare as the result of rheumatism; it is much more likely to be the result of strain or syphilis, and hence if present in a woman is nearly always syphilitic. Syphilis of the air-tubes occurs with frequency which decreases rapidly with the distance from the pharynx. It is three times more frequent in the pharynx than in the larynx, while in the trachea and bronchi syphilitic affections are rare. It is extremely important to recognise the laryngitis; practically the diagnosis has to be made from tubercle. In almost all cases of tubercle, some signs can be detected in the lungs, though they may be slight. The most characteristic appearance is the pyriform swelling of the arytenoid cartilages and aryteno-epiglottidean folds. This swelling is really an infiltration; it is of a yellowish colour, and, with its vessels, is sometimes spoken of as an injected œdema. The vocal cords are often affected, they lose their polish, present erosions, and the edges are often serrated. The epiglottis is less frequently affected, and then always on its laryngeal surface.

Syphilis differs in nearly all these particulars: the swelling is much more red and inflammatory, and is commonest on the parts adjoining the pharynx; the arytenoid region is rarely affected, and the epiglottis is frequently affected, and then on the lingual surface. Ulcers are sharply cut, and larger than in tubercle. If not adequately treated serious stenosis may result; and I have seen two cases which illustrated the important fact that sometimes, even in syphilis, healing will not occur before a preliminary tracheotomy has been done. Syphilis of the trachea and bronchi are very rare. I have not seen a case; but it should be remembered, for if a main bronchus is affected, it may produce symptoms of obstruction and resemble aneurysm or mediastinal tumour, but the cough has not the peculiar brassy quality, and there is no laryngeal paralysis. Syphilitic disease of the lungs is so rare that it hardly enters into clinical medicine. It never causes destructive disease like

tuberculosis. Several cases are, however, recorded in a recent number of the *Liverpool Journal* which may fairly be said to satisfy the tests. I have met with two cases of lung disease of interest in this connection, in the subjects of syphilis. In one there were tertiary lesions of the skin, and choroiditis, with signs of consolidation about the hilus and apex. Repeated examinations for tubercle bacilli were negative, and mercury and iodide certainly caused marked improvement.

The other case came to the *post-mortem* table, and certainly the lesions were of a very unusual character, and might readily have been syphilitic: here, also the tubercle bacillus was absent, though looked for many times. The frequent examination of the sputa is an important point.

*Syphilis of the Nervous System.*—It is necessary, both from the point of view of pathology and of therapeutics, to draw a sharp distinction between the true syphilitic affections of the nervous system, and those which occur in persons who have had syphilis: these affections, known as meta- or post-syphilitic, are locomotor ataxia and general paralysis. They are very important, and may present many difficulties in diagnosis, especially in the case of suspected general paralysis of the insane. I cannot discuss them now, but may say that I do think anti-syphilitic treatment, if exhibited early, does sometimes undoubtedly arrest these terrible diseases. At a later stage such treatment is useless, if not positively harmful. A true syphilitic disease shows the characteristic lesions, which are nearly always either—

- (1) a vascular change, notably endarteritis;
- (2) a diffuse round-celled exudation, especially prone to affect the meninges;
- (3) a true gummatous formation—which is quite rare.

With regard to their frequency, of 1,000 hospital admissions I find 15 have suffered from true syphilis of the nervous system. They constitute a grave class of disease, but within certain limits react well to treatment. These limits are sharply defined, and it is well to emphasise, when dealing with any kind of lesion of the central nervous system, that damage once done, is irremediable if it has proceeded to actual destruction of the nervous substance, for repair of the essential elements does not occur. The natural history is as follows: the syphilitic virus gradually produces a pathological alteration in the tissues, without at this time causing symptoms; then suddenly, if the lesion has been one of the vessels, the blood-supply is obstructed. Symptoms due to interference with the nervous functions make their appearance, due to anæmia and pressure from the exudation of fluid. If untreated, death may result from the extent of the lesion and the importance of the parts rendered functionless, or the exuded fluid may be absorbed and pressure relieved, circulation re-established, and finally the permanent effects are proportional to the amount of actual destruction of nervous substance which has taken place. So, the natural history of a syphilitic vascular lesion does not differ in any way from that of the effects of vascular disease from other causes.

Specific treatment can do two, and only two, things:—(1) It can remove the specific newly-formed tissue which has caused the symptoms; or (2) it may prevent the pathological condition present elsewhere from increasing, which in its turn may cause symptoms. It is powerless to alleviate the damage already done, and it has no specific effects on the exudation of fluid, to which symptoms are often due. It is the same when we are dealing with the new formation of round cells about the meninges or with a gumma. It is well then to have precise ideas as to the real use of anti-syphilitic remedies, otherwise a correct prognosis is impossible.

*Syphilitic arteritis* may occur in the brain and spinal cord. It occurs early after the primary affection, often in from six months to two years, though occasionally at a later period. When the resulting thrombosis is in an artery of the brain, there is a

sudden monoplegia or hemiplegia, often a temporary aphasia.

The distinguishing features of the seizures are—

- (1) The age and sex, though, of course, syphilis is sometimes acquired in advanced life.
- (2) The presence of prodromal symptoms, notably nocturnal headaches, vertigo, insomnia, and loss of memory. In some cases the pain in the head is of a neuralgic nature, and may be treated with palliative remedies until a hemiplegia of aphasia gives the clue.
- (3) The presence of syphilitic lesions elsewhere, especially periostitis, the scars of syphilitic ulcers, leucoderma, or early arterio-sclerosis.

A young man with sudden hemiplegia usually suffers from syphilis or mitral stenosis; in young women syphilis is also to be remembered; but I have seen a number of cases of hemiplegia in which the thrombosis was probably due to a blood state. In these cases of thrombosis there are rarely severe apoplectic-form symptoms; consciousness may not be lost at all, as is so commonly the case when there is intracranial hæmorrhage. It must be remembered, however, that syphilis is sometimes the cause of cerebral hæmorrhage in young people. The disease of the vessels goes on to aneurysm formation. I published a short time ago such a case: the patient was a young woman in whom there was no evidence of syphilis, though it could not be excluded. I show you some of the arteries from her brain; they are very characteristic and on one of them an aneurysm the size of a big pea had formed and ruptured.

The prognosis in simple thrombosis is fairly good, though the points I have mentioned on the limits of therapeutic action ought to be borne in mind: the patient should be treated by inunctions, which in any urgent case are best persevered with until the gums are just touched; only in this way can we be certain that sufficient mercury has entered the system. Syphilitic hæmorrhage is, however, a very fatal disease, and so is thrombosis when the basilar artery is affected, as evidenced by complete paraplegia and paralysis of the upper limbs.

Meningitis is usually chronic; it may affect the dura or the pia, or spread from one to the other, or the bone of the skull may be invaded. Irregularly and widely distributed affection of the cranial nerves is strong evidence of syphilis. The meningitis has a peculiar predilection for the oculomotor nerves, and here also the palsy is often asymmetrical and irregular, and the paralysis may vary from time to time. The meningitis, of course, cannot pick out separately the nerves for the internal or external eye muscles, and this forms a valuable distinction from the ophthalmoplegia of nuclear origin, where, owing to the distance which separates the several nuclei, the pupil may escape, but the external muscles may be paralysed. Unilateral ophthalmoplegia is also a sign of interference with the nerves at the base, and hence may be due to syphilitic meningitis. Often the same prodromal symptoms that herald thrombosis may precede meningitis; and if the meningitis be on the convexity of the brain, Jacksonian epilepsy may occur.

Occasionally general convulsions exactly like those of epilepsy occur: they are to be distinguished by the age of the first attack, the presence of nocturnal headache, loss of memory, and attacks of temporary aphasia. Epileptiform convulsions are also well known as a symptom of general paralysis. Optic neuritis is rare in cortical meningitis, a point of distinction from cerebral neoplasm; though it must be remembered that a tumour of the cortex may not give rise to optic neuritis until late, and in fact ought to be recognised before this occurs. The peculiar characteristic symptoms of syphilis already mentioned, its random and widely-spread distribution, the history and the presence of associated symptoms, should enable one to form a diagnosis.

A very important point is the diagnosis between cerebral syphilis and general paralysis of the insane.

The chief points of distinction are, that in the latter

the cranial nerves are not paralysed; there is the true Argyll-Robertson pupil, not a fixed immobile pupil; the peculiar tremor of tongue and lips, characteristic mental symptoms, frequent epileptiform and apoplectic seizures, and the progressive advance to a fatal termination, with the uselessness of anti-syphilitic remedies, are other marks of general paralysis. These remedies are usually of marked benefit in true cerebral syphilis; sometimes, however, they quite fail. I have a melancholy example in my mind of a man who came to see me from this district with ophthalmoplegia, undoubtedly a true syphilitic meningitis; this had been completely cured at the Eye and Ear Infirmary by Mr. Hugh E. Jones, but returned in spite of any treatment, spread to the opposite eye, and produced complete blindness as well as motor paralysis. Syphilis in the spinal cord is due to the same lesion as in the brain, and is manifested chiefly as a meningitis or myelo-meningitis, or is due to a thrombosis of the spinal vessels, producing paraplegia. The prominent symptoms of the meningeal form are pain in the spine, pains in the hips, and girdle pains, all indicating affections of the roots; then follow gradually symptoms of interference with the conduction tracts of the cord, with varying degrees of motor or sensory paralysis.

The diagnosis is to be made by the history, the age of the patient, the associated symptoms often of cerebral syphilis, headache, hemianopsia, diplopia, affections of the pupils, choroiditis, etc.

Treatment may be singularly efficacious. Syphilitic thrombosis shows itself, as do all vascular affections of the nervous system, by its sudden onset, producing paraplegia. It has now, I think, been quite proved that the great majority of cases of sudden paraplegia, the so-called acute myelitis, are due to syphilis. In the course of a few days or hours the patient may lose the complete use of both legs, marked loss of sensation is present, and the bladder and rectum are early affected. Now there is nothing in these cases except the history and the known pathology to enable a diagnosis as to cause to be made. The affection occurs quite early after the infection, from six months to five years being the usual time. It may rapidly run a fatal course, or later considerable regression of the symptoms occurs and the patient appears as our old friend—a spastic paraplegic. The disease is, as I have indicated, very dangerous; a water-bed and the most careful attention to the bladder and the prevention of bedsores is required; a diaphoretic, with some ergot and belladonna, may be given.

Is anti-syphilitic treatment useful? I think it may be. The injection should be carefully practised, avoiding the same place for fear of sores. I have seen several remarkable recoveries, one in a man with absolute motor and sensory paralysis and complete incontinence, who is now walking about the Liverpool Exchange.

One final word about treatment. I have mentioned to you that these syphilitic affections are prone to recur, perhaps in other parts of the nervous system. It is well, therefore, when the acute manifestations have been subdued, to institute a prolonged course of iodide, perhaps with small doses of mercury, especially if the affection has occurred soon after the primary infection. The combination of the drugs is more beneficial than the exclusive use of either. A good plan sometimes is to alternate the treatment. One use of the iodide is probably that it liberates the mercury already in the tissues, and so revives its specific action.

DR. LITTELJOHN's resignation as medical officer at the Hanwell Schools has been announced at a meeting of the managers of the Central London School District, held under the presidency of Mr. T. Pallister Young. He has held the position since 1870. It was unanimously resolved to accept the resignation with regret, and to send a sympathetic letter to the medical superintendent, whose retirement is due to ill-health.

## THE INOCULATION ACCIDENT IN MANILA, PHILIPPINE ISLANDS.

BY PROF. W. M. HAFFKINE.

THE following article has been sent us for publication:—

### "ACCIDENTAL INOCULATION WITH THE VIRUS OF PLAGUE.

"By Paul C. Freer, M.D., Director, Bureau of Science, Manila, P.I.

"Last autumn, as the unfortunate result of the accidental contamination of the cholera vaccine with a culture of plague bacilli, a number of natives were inoculated with plague, and several died. The occurrence makes of interest the following account of the work with the cholera vaccine.

"For the last three years Dr. Richard P. Strong, of this bureau, has been working on a cholera vaccine which consisted of an extract of the killed, digested and filtered organisms, later modified to a mixture of such an extract with one obtained by shaking on a shaking machine the living organisms in distilled water and then filtering. Obviously this product is always carefully tested, and is absolutely sterile, and the health department has used it on about 7,000 persons in the Philippines. One-half of the prisoners in the Government prison at Bilibid were vaccinated with this vaccine, and one-half unvaccinated. The same was done in a number of villages in the surrounding territory. Needless to state, no bad results followed from these vaccinations. There is a moderate general reaction following the inoculation, but the local reaction is very slight. The reaction from vaccination with this cholera vaccine is not as serious as that which frequently follows the small-pox vaccination, yet a high blood immunity results.

"Subsequent experiments in the town of Angat, where 1,078 persons were vaccinated, showed that after vaccination there were 122 cases of cholera, 121 of which were among the unvaccinated, and only 1 among the ones vaccinated. In the prison we had no further epidemic of cholera after the vaccination, but no conclusions can be drawn because the cholera was stopped by sanitary measures. It may be stated, however, that since the vaccination we have had 20 cases of cholera, 18 of which were among the unvaccinated and 2 among the ones vaccinated.

"Dr. Strong continued his work on immunity against cholera by vaccination, as he was convinced that this means was one which would aid in the prevention of large epidemics in the future, since it is known that apparently healthy people frequently carried about in their intestines cholera spirilla, which are passed in the stools, and hence quarantine and sanitary measures cannot always be considered effective safeguards against a cholera epidemic. Certainly, the end sought for is a great one, and the results satisfactory.

"Last year, in a Medical Congress at Berlin, the method of vaccination by means of the entire organism and not by its extracts was advocated. Haffkine has urged the use of the living organism, and believes that by its use a higher immunity can be obtained. Dr. Strong, of necessity to complete his argument, needed to make some vaccinations by this method, as he was convinced that it was not superior to the one generally employed by this laboratory, but, obviously, with such arguments in literature others would come forward attacking his results. In employing the living organism, it is necessary to use a 24-hour old culture, owing to the fact that after this time changes take place in the culture owing to the formation of ferments, death of a large number of bacteria, etc., and, consequently, while the method allows of every test as regards the purity of the cultures up to 24 hours before their use, after this time (when many cultures are employed) no satisfactory test of its purity can be made, and no test on animals can be carried on, since the cultures must be inoculated 24 hours after their preparation. Inoculations had been carried on in Bilibid several days without accident. On the day of the misfortune 24 men were inoculated, but this was not compulsory.

The history of this vaccination is about as follows:—

"The culture was carefully carried out and identified, and was known to be a pure culture of the cholera organism up to 24 hours before the time when the vaccination was made. A large number of tubes of cholera media were inoculated from these pure cultures and placed in the incubator. On the following morning the cultures were each suspended in 1 cubic centimetre of saline solution, the whole mixed, and inoculations, as was necessary, made immediately after the preparation of the suspension. It is supposed that someone placed a 48-hour virulent plague culture among the cholera cultures, the blue pencil marks which designated the culture having been erased from the glass by handling. This view is supported by the fact that on the afternoon of the day of inoculation a 48-hour virulent culture was missed from the incubator. It was known certainly that one of the five plague cultures prepared two days previously, as was shown by Dr. Strong's note-book, had been removed from the incubator, but it was not until two days later, when he wished to examine the opsonic index of five guinea-pigs, for each one of which a 48-hour richly-grown culture had been prepared, that the plague culture was missed.

"It was proved by a technical committee of three physicians appointed by the Governor-General to investigate the matter that a 48-hour richly-grown plague culture spread over the entire surface of the entire slant resembled some of the cholera cultures so strongly that they were unable to identify or to pick out such a plague culture by its gross appearance when it was placed among a number of the cholera cultures of the strain employed. It was also shown that a hanging-drop preparation and the stained microscopic one made from the mixed suspension of all the cholera cultures contaminated with the plague one (as used for the human inoculations) did not reveal the suspicion that the fluid was contaminated with plague bacilli, since no bipolar staining organisms were visible, and, evidently, the plague bacilli were in too small numbers, or those present did not show any sufficiently distinctive morphology to separate them from the pleomorphic cholera organisms in the saline solution. Nevertheless, this same suspension, in which plague bacilli were not detected by microscopic examination, when injected subcutaneously into guinea-pigs and a monkey, caused, after several days, death from plague infection. It has not been ascertained who placed the plague culture among the cholera ones after all possible tests of the cholera culture had been made. An investigation of the entire matter was pursued by the Government prosecuting attorney at our request, and later the Governor-General, in order to satisfy public opinion, appointed a committee of eight, six Filipinos, one American, and one Englishman, three of which committee constituted a technical committee, for investigation.

"While the serum division of this laboratory is also in charge of Dr. Strong, and while this division prepares our regular cholera vaccine, it must be clearly understood that the regular preparation of our cholera prophylactic had absolutely no connection with this matter, and that the vaccine used by Dr. Strong on the day of the accident is entirely distinct from the preparation with which he is identified. The method used on the last 24 prisoners is the one which is best known by the names of 'Ferran' and 'Haffkine.' It is perhaps unnecessary to add that the laboratory has prepared several million units of vaccine virus and several thousand doses of plague prophylactic which have been used (in addition to the cholera prophylactic) with good results and without accident."

# I.

The study of vaccination against cholera, according to the method worked out in 1890-93, in the Paris Pasteur Institute, began in India in April, 1893—that is, some thirteen years previous to the Manila accident. The procedure which was adopted for cultivating and inoculating the vaccines was described, with great detail, in a pamphlet published in Lahore, Punjab, in 1894, by Mr. E. H. Hankin, M.A., Chemical Examiner and Bacteriologist to the Government, Surgeon Lieut.-Col. Ch. H. Owen, I.M.S., Medical

Adviser to the State of Patiala, and myself, under the title of "Technique of Haffkine's Anti-Cholera Inoculation." The pamphlet was reproduced in the *Indian Medical Gazette*, Calcutta, in June, 1894. A more detailed version of the same "Technique" was published in the journal just mentioned two years later, in June, 1896, by Lieut.-Col. (then Surgeon-Captain) Hare, I.M.S., the present Sanitary Commissioner of Eastern Bengal and Assam. In the issue of the same journal for November, 1896, in an article entitled "Technique of Haffkine's Method of Preparing Fixed Cholera Vaccine," the same officer described the method of transforming cholera virus into the vaccine strain.

The extent to which the above technique rendered the operation safe, and the facility with which it was learned by non-specialists and by subordinates, may be gauged from the following facts.

The inoculations were at first carried on by myself, and between 1893 and 1896 were introduced in over 100 towns and villages in the Indian Plains and the Himalayas. I prepared the vaccines in trains, while travelling from place to place, in the ordinary passenger carriages, and at railway stations, while waiting for the arrival of trains; also in tents, in "dāk-bungalows" and rest-houses; in rooms placed at my disposal for a day or two in dwelling-houses, and transformed for that time into "laboratories"; and sometimes (in Calcutta and Agra) in established laboratories, in which various work was carried on at the time by other workers. Between April, 1893, and July, 1895, 42,197 people, who received in all close on 70,000 injections, were inoculated under these conditions, and in 1896 a further 30,000 were so operated on. A large proportion of the inoculated lived under medical and administrative supervision, so that any unusual effect of the inoculation could not have escaped notice. Thus, the operated on of 1893-95 comprised officers, non-commissioned officers and men belonging to 64 British and Indian regiments; contract labourers of 45 tea plantations in the Brahmaputra and Surma Valleys of Assam; inmates of nine civil gaols; children of boarding and other schools, etc.

In 1894 the Municipal Corporation of Calcutta voted a grant to its Health Office for applying these inoculations experimentally. A Hindu Medical Inspector, Mr. Jonomanjoy Chowdry, was put on to this duty. He was assisted in the preparation of the vaccines by two other Hindu officers, Messrs. Jogendranath Dutt and Sasi Bhusan Ghose, of the Calcutta Health Office. None of these doctors had been acquainted with bacteriological work before. Apart from the preparation of the cholera vaccine, which, after a period of instruction, they were left to carry on independently, they became soon engaged in a variety of other kindred work, notably in connection with infectious diseases affecting the ponies, buffaloes, and bullocks in the "gowkhanas" of the municipal scavenging department; with outbreaks of rinderpest and other epizootics reported from Calcutta and Howrah; and in connection with the then Health Officer's studies of pustules and vaccine lymph, in the municipal vaccine dépôt. Cholera inoculation in the bustees and suburbs of Calcutta, with cultures prepared in the Health Office, was carried on daily for two years, and the results were closely followed by various members of the Municipal Corporation. The number of persons inoculated was 7,690. About two-thirds of them underwent inoculation twice, at an interval of five days, so that the number of injections of vaccine performed was about 13,000.

In 1896 anti-cholera inoculation was started at Purulia, on the Bengal-Nagpur Railway. At first Surgeon-Captain (now Major) J. C. Vaughan, I.M.S., Superintendent of the Campbell Medical School, Calcutta, then Deputy Sanitary Commissioner for the Chota Nagpur Circle, was in charge of the work. Two Hindu assistant-surgeons were appointed to operate under his orders. Surgeon-Captain Vaughan was, after a few months, ordered away to the Tirah campaign, and from that time on one of the assistant-surgeons, Gopal Chunder Mukerjee, was left in independent charge, the other co-operating with him. In this dépôt the operations were performed every day

for eight and a-half years, till the end of 1904, and the number of persons inoculated was as follows:—

In 1896	...	...	4,413
„ 1897	...	...	10,950
„ 1898	...	...	4,296
„ 1899	...	...	2,388
„ 1900	...	...	13,291
„ 1901	...	...	3,453
„ 1902	...	...	3,144
„ 1903	...	...	2,202
„ 1904	...	...	1,623
In all	...	...	45,760

The material for these inoculations was manufactured, examined and used in an improvised laboratory by workers who had had before no bacteriological training. The inoculated were almost exclusively coolies contracted for transport to Assam, and who were, at the time of inoculation, and during their subsequent journey and service, under the supervision of Government and labour supply officials. The slightest mishap would have at once been known to the emigration authorities and reported upon.

In none of the above operations has an untoward result at any time come to knowledge, and quite certainly no accident of any gravity has ever occurred. Anti-cholera vaccination has thus been demonstrated to be as free from danger as any method devised by man.

## II.

Just as in vaccination against small-pox and inoculation against hydrophobia, as well as in Professor Kolle's inoculation which the Manila laboratory has advocated and applied against plague, the vaccine used in anti-cholera inoculation is a live virus, and is not sterilised before injection. Nevertheless, the details mentioned in the preceding paragraphs and referring to a long testing in India, indicate that the methods followed in the preparation and use of that vaccine render it, even in relatively inexperienced hands, safe from contamination, and eliminate sources of mishap.

Again, neither in the anti-cholera vaccine, in the emulsion of spinal cords containing live hydrophobia virus, as used for anti-rabic inoculation, nor in the live virus of small-pox vaccine lymph, nor in any of the sera and drugs used in hypodermic injections in man and animals, can contamination with harmful germs be detected with certainty by the microscope; but obviously this does not mean that either of the methods mentioned, now so extensively practised, is insecure. In the anti-cholera inoculation, the examination by the microscope is an adjunct so important that, when applied in the way in which it has always been applied in India, an accident such as occurred in Manila is impossible, and an extraneous culture like that of plague would be detected immediately. Nevertheless, entire elimination of mishap is secured, obviously not by microscopic examination alone, but by an *ensemble* of operations of which some precede and others follow that examination, and by the general dispositions of the work.

## III.

In the accident at Manila it is essential to note that the cholera vaccine did not get contaminated by plague spontaneously. Such an eventuality may be treated as outside all practical possibilities. Every bacteriologist of experience will take on himself to say that the spontaneous invasion of a bacterial culture by germs of cholera, plague, glanders, anthrax, diphtheria, tubercle and certain other specific microbes is not to be thought of any more than the spontaneous contamination of such a culture with arsenic or strychnine. There are a few pathogenic species—like those causing abscesses, for instance—which are, upon occasions, found to contaminate cultures and other materials. In Manila a plague cultivation, presumably free from admixtures of any kind, was put by the operator into a watery suspension of cholera cultures, the latter probably being at the time quite pure and uncontaminated also.

The accident became possible by the operator deviating, amongst other points, from the following two rules prescribed in the anti-cholera inoculation—

viz., the contents of the culture tubes should not have been mixed; and each tube, immediately before being used, should have been, apart from other examination, submitted to an examination by the microscope. Under these circumstances a plague culture would have never passed for a cholera culture.

It is not stated that the material injected into the men in Manila had been examined by the microscope, but the Technical Committee of Inquiry have found that when they mixed, in an experiment *ad hoc*, the contents of one cultivation tube of plague with that of a large number of cultivation tubes of cholera (as had been actually done at the time of the human inoculation), and examined a drop of the mixture, the plague bacilli were overlooked under the microscope. Such a result is, of course, only too probable.

## IV.

The details of the Manila accident reported by Dr. Freer tend to show that its occurrence did not stand in connection with the degree of perfection or deficiency which belong to cholera vaccination or to any bacteriological method as such.

In all pharmacies and shops where collections of drugs are kept, simple dispositions are adopted, on the responsibility of those in charge, for making it impossible for dangerous materials to get mixed with harmless ones. Obviously these measures had, at the time of the accident, not been in force at Manila, and it must be presumed that some particular circumstances which existed at the time did not allow of the necessary dispositions being taken.

It is, further, a practice with those in possession of materials of various kinds, particularly harmful ones, to differentiate these by inscriptions or marks of identification. The first action of an apothecary, when handling his phials, is to look at the label, independent of any other mode of examination—chemical, physiological, or other—which may be at his disposal for identifying the materials. The labelling of cultivation tubes is one of the articles of instruction mentioned in bacteriological text-books and lectures. In the pamphlet on the "Technique of the Anti-Cholera Inoculation" referred to above, the procedure is enjoined on p. 8, paragraph 12, where it is stated: "Mark the inoculation tubes unmistakably, in order that the kind of vaccine they contain and the date of their inoculation shall be known." The operator who omits to provide his preparations with clear inscriptions, or omits to take notice of them when using the preparations, renders obviously nugatory the whole of the safeguards, however perfect, which have been devised for preparing his materials in a pure condition.

In Manila, where the tubes of vaccine for inoculation in man had to be incubated in the same box as tubes of virulent plague, and other persons than the vaccinators had access to the same incubator and to the same batches of tubes, it is stated that the inscription on the tube was not ascertained previous to using it. The accident was, therefore, in every way of the same kind as would be incurred by a pharmacist mixing up a poisonous substance with the drug which he is preparing, and it was preventable also in the same way as such accidents are prevented in pharmacies.

## V.

The idea that the Indian method afforded no possibility of avoiding the accident appears to have been based on the following considerations mentioned by Dr. Freer:—"While the method allows of every test as regards the purity of the cultures up to 24 hours before their use, after this time (when many cultures are employed) no satisfactory test of their purity can be made, and no test on animals can be carried on, since the cultures must be inoculated 24 hours after their preparation." The accident was caused by the mixing up of a plague culture with the cholera vaccine at the very moment of using the latter. Obviously, no test applicable 24 hours or any longer interval before that moment, nor any test applicable a shorter period, even one hour, before, could have prevented the result of a confusion thus made. To avoid such a confusion—once the general dispositions in force at the time permitted of its occurrence—a test or tests were

required applicable at the moment of using the tubes. The most direct of such tests were those mentioned already, viz.: (1) the reading of the inscriptions made for that purpose on the receptacles; and (2) the examination under the microscope of the contents, in the manner prescribed for the anti-cholera inoculation. There were also certain other aids, but the special object of the present article does not seem to require entering into them.

## VI.

The Manila officers have gracefully recognised as conclusive the results of the Indian cholera vaccination studies, and have themselves contributed not a little to the subsequent investigations on the matter. A few years ago, before introducing that vaccination in the Philippines, the very able director of the laboratory there made, in the Institute for Infectious Diseases in Berlin, a study of the vaccine used in these operations. The vaccine—as described in the publications referred to previously—is a strain of cholera germs transformed into a virus of exalted, fixed potency, by cultivating it, in accordance with certain rules, in the peritoneal cavity of the guinea-pig. The bacteriologists in Berlin compared this vaccine, from the point of view of its immunisation properties, with the natural strains of cholera germs maintained by cultivation in laboratories, and convinced themselves of the significance of the transformation imparted to the vaccine. Consequently, in the Philippines, a strain has been adopted, for preventive inoculation in man, which is prepared and maintained in the way in which this is done in India; but, instead of operating with that substance itself, they advocate the plan of leaving it to soak in water, at the temperature of the incubator, and using the resulting soluble extraction, a plan to which, as Dr. Freer mentions, it has been objected at the last International Medical Congress in Berlin that the extraction might not have the protective effect which the vaccine itself had. The Manila officers are under the impression that one of the advantages of the watery extraction is that it is free from the possibility of misadventure which they have had with the vaccine. The same department of the Manila institute that prepares the extraction of the cholera vaccine prepares also soluble products of other microbes, such as the toxin of diphtheria; that of tetanus, of which the admixture of a few c.c.s. would, of course, suffice to kill a horse; probably, solutions of snake venoms for the preparation of anti-venene, and so forth. If these microbial toxins and solutions, or, for the matter of that, any alkaloids or other drugs were to be so kept as to permit of their being inadvertently mixed with one another; if, before using them under such circumstances, the inscriptions on the receptacles were not ascertained; physical differences of the contents overlooked; and the contents mixed together and used; that is, if a concurrence of circumstances took place identical on all points with that which they have had the misfortune of having at the time of the late accident—the extraction of the cholera vaccine would obviously be exposed to the same possibility of misadventure as has occurred in the use of the vaccine. Of course, it is not suggested that the above is the condition prevailing normally in the Manila laboratory. The latter has, in a few years, and most deservedly, taken a place amongst the first-class institutions of its kind in the world. It is only unavoidable now to make it clear that their accident has not been conditioned by the peculiarities of the anti-cholera vaccination method, as they believe it has.

## VII.

Referring to the facts mentioned in Section 3 of Dr. Freer's article ("Subsequent experiments in the town of Angat. . . . In the prison we had . . . and two among the ones vaccinated"), they do not, unfortunately, convey indications as to whether the extraction of the cholera vaccine confers on man the immunity against Asiatic cholera as has been obtained with the vaccine. Such an indication would have been most welcome to me, but obviously Dr. Freer had no data yet for making any definite affirmation on the matter. In the case of the town of Angat, the

number of non-vaccinated inhabitants, among whom 121 cases of cholera occurred, and the degree of exposure to infection, in the case of the vaccinated and of the non-vaccinated, have not been made known, and consequently a deduction from the figures given is impossible. In the Government prison in Bilibid, where one-half of the prisoners had been vaccinated and one-half not, after which event 18 cases of cholera occurred among the non-vaccinated and 2 among the vaccinated, the result would have been quite important, and, under requisite conditions, even conclusive; but, presumably, between the time of vaccination and the date of the cholera occurrence changes of which details are not related in the article had taken place in the composition of the prison population; for Dr. Freer states that no conclusion could be drawn from the facts related about that prison.

It is to be hoped that the above explanations will not be viewed as implying any want of consideration for the Manila scientists, whose efforts, ever since the establishment of their laboratories, have enriched science with numerous contributions of a truly remarkable character.

## OPERATING THEATRES.

## ST. MARY'S HOSPITAL.

ENDOSCOPIC DILATION OF AN OESOPHAGEAL STRICTURE WHICH WAS IMPASSABLE TO ORDINARY BLIND BOUGIE-ING.—DR. WILLIAM HILL operated on an emaciated man, æt. 46, under the care of Dr. Willcox. The patient had suffered from progressive dysphagia for nearly a year, and had practically been unable to take solid food for nearly the same period. His illness commenced 14 months previously with an attack of hæmatemesis; he had had vomiting immediately after taking food just before this. His gastritis was evidently alcoholic, and he also suffered from alcoholic neuritis.

FIG. 1.

FIG. 1.—Deep Pharyngoscopy and the first stage of Oesophagoscopy; the distal end of the long tube-spatula is in the deep or postcricoid pharynx, thus enabling the region of the upper orifice of the gullet to be examined.

Dr. Hill pointed out his dysphagia was certainly not due to paresis of the gullet, for in such cases the bougie is easily passed.

Six months previously a surgeon had failed to pass a bougie through the stricture by the blind method, and two months later a physician was similarly unsuccessful. The stricture was localised as commencing at a distance of 9 in. from the incisor teeth—i.e., about 2 or 3 in. from the introitus oesophagi. Dr. Hill remarked that it was a matter of common experience that dysphagia from organic stricture of gullet,

whether cicatricial or malignant, is not infrequently temporarily improved by bougieing, and as the man had lost 4 st. in twelve months, it was resolved to resort to œsophagoscopy with the twofold object of endeavouring to determine the nature of the lesion by direct inspection, and to attempt dilation of the stricture by means of graduated bougieing, cautiously carried out under direct vision. The patient was anæsthetised with chloroform, and the possibility of spasm of the larynx rendered less likely to occur by means of the local application of 10 per cent. cocaine in a solution of adrenalin. Brüning's œsophagoscope was then passed; the gullet was found healthy for the upper 2½ in. of its extent, when the passage was discovered to be suddenly narrowed to a marked degree. The constricted lumen was reduced to a mere depression during expiration, but during inspiration the tube opened, presenting a circular lumen with an inflamed reddened margin, the lumen being about 4 millimetres in diameter. The mucosa immediately above the strictured area was distinctly œdematous. There was no visible ulceration. Dr. Hill said that strictures due to subacute œdematous inflammation offer little resistance to the passage of a bougie, and in order to determine whether the lesion was of this nature, a No. 6 Mackenzie bougie (*i.e.*, 6 mm. in diameter) was tried; it, however, failed to pass through the strictured area; No. 5 was also tried without success. The stricture was therefore evidently of a hard variety, and not of the soft, œdematous kind. A No. 2 filiform bougie (2 mm. diameter) was, however, easily introduced, and the stricture was then gradually dilated up by the insertion of larger and larger bougies, until a No. 9 (*i.e.*, 9 mm. in diameter) was with some difficulty passed; it was allowed to remain *in situ* for

FIG. 2.

FIG. 2.—Second and third stages of œsophagoscopy; the tube is passed into the upper part of the gullet, and the proximal end of the tube is then shifted to the angle of the mouth opposite the molar teeth; the extension tube is next slowly inserted, and the gullet explored as far as may be necessary compatible with safety. By this method, in suitable cases of stricture, dilation by graduated bougieing, and even the application of radium, can be carried out with precision.

a few minutes, but this had little further dilating effect, for it was tightly gripped, and it subsequently was found impossible to pass a larger size. No bleed-

ing ensued, and this, Dr. Hill remarked, pointed to the fact that ulceration was not present.

The patient frequently stopped breathing during the time the endoscope was in the gullet, and on his return to the ward this phenomenon continued at intervals during the next three-quarters of an hour, and artificial respiration had at times to be resorted to. Respiratory trouble of this kind, Dr. Hill said, is observed every now and then in cases of prolonged œsophagoscopy examinations under general anæsthesia.

Dr. Hill subsequently pointed out that the result in this case was by no means so striking and gratifying (as regards the relief of dysphagia) as has been sometimes observed in similar cases of endoscopic dilation. The man was, it is true, able to get down with some difficulty bread and butter and mince, but soon relapsed. Considering that the narrowed tube had been dilated up to 9 millimetres, this was decidedly disappointing.

A fortnight later the procedure was repeated, and an attempt made to dilate the stricture still more by the insertion of a laminaria tent of 6 mm. diameter. The process was, however, very slow and the patient's condition under the anæsthetic, etc., did not permit of a sufficiently prolonged sitting to obtain any substantial gain in the diameter of the narrowed portion of the gullet. A soft, long gastric tube of the calibre recently employed by Symonds in such cases (*viz.*, 6 mm.) was then passed through the gullet into the stomach, and fastened at its proximal end to the teeth; on account, however, of the gastritis, this was vomited up a few hours later.

Dr. Hill remarked that, although an endoscopic examination in this case did not absolutely clear up the diagnosis, the balance of evidence pointed to malignant disease. The stricture was seen to be annular, and this type of stricture, if cicatricial, would be hardly appreciably dilatable without a cutting operation, whereas in this instance the lumen, by graduated bougieing, had been enlarged from 3 to 4 millimetres to 9 millimetres; moreover, the œdematous condition of the mucosa in the region of the upper end of the obstruction was much more suggestive of epithelioma than of a cicatricial stricture. The failure to dilate the narrowed gullet up to a diameter of 13 or 14 millimetres, which would have resulted in substantial though temporary relief of the dysphagia, had left the patient in the condition that the next palliative measure—gastrostomy—was merely a matter of time. Had the man been a person of means, instead of a hospital patient, another method of treatment might have been tried, *viz.*, the insertion of a tube containing an adequate quantity of radium into the gullet, as is practised in Paris. In this country, however, no hospital as yet, so far as Dr. Hill is aware, possesses the necessary tube containing 5 centigrammes of radium bromide, on account of the great cost, *viz.*, £800. In private practice the matter is different, and judging from the very definite improvement in two of his patients, who are being treated by Dr. Finzi with a 5 centigramme radium tube, he is hopeful that the claims made by Einhorn some years ago, and by Guisez, of Paris, quite recently, may be confirmed as regards the value of radium in early carcinoma of the gullet.

#### CONVULSIONS IN CHILDREN.

INFANTILE convulsions are of everyday occurrence, and yet it may be useful to review from time to time the several varieties of treatment recommended by the best authors, as in these cases parents get frightened and impatient, requiring prompt treatment from the medical attendant.

The first thing to do in presence of convulsions is

to determine the cause of the accident, and, once the causal treatment is instituted, appropriate symptomatic treatment remains to be applied.

All authors, including MM. Hutinel and Babonneix, who have written extensively on the subject, recommend that the child be first freed from all wrappings, and everything suppressed that might impede the normal function of the lungs. This done, recourse will be had to one or other of the following means: bathing, inhalation of chloroform or oxygen, compression of the carotids, blood-letting, saline injections, revulsions, administration of antispasmodics.

Balneation may consist in baths or simple wrapping in the wet sheet. Cold baths might be given, according to Espine, where a high temperature accompanies the convulsions, but should not be employed for very young children (Ausset). But the best method is that of warm baths, which possess the advantage of suiting every variety of convulsions. The patient may be kept in it one or two hours at a time, but the application at the same time of cold compresses to the head is indispensable to complete the treatment.

Inhalations of chloroform have been frequently employed with advantage; but, according to Deseille, they are counter-indicated in convulsions provoked by indigestion; they have been especially useful in very young children.

M. Moussous recommends inhalations of oxygen where the convulsions threaten the patient with asphyxia (cyanosis of the face and the extremities).

Compression of the carotid has been employed with success in some few cases, but the difficulties of such a treatment are obvious.

Blood-letting is indicated in three different circumstances: venous congestion of the brain, lesions of the coverings of the brain, and, above all, uræmia (Picot). It consists in the application of one or two leeches to the mastoid process (Ferrand), or, better still, to the malleolar region (Guersant, Deseille).

Different authors have used injections of artificial serum. For M. Moussous this method would be especially indicated in cases where the convulsions appeared to be the result of intoxications.

As to revulsion, M. Ausset is of the opinion that it is better to abstain from employing it except in case of spasm of the glottis.

Of the numerous drugs called "antispasmodics," chloral, bromide of potassium, and antipyrin alone claim attention.

Chloral has the most rapid effect of the three, but is counter-indicated in cases of cyanosis with asphyxia (Comby).

The action of bromide of potassium, though less prompt, is quite as efficacious, given at the dose of 10 or 15 grains a day. The two drugs, chloral and bromide of potassium, might be given together, the latter during the day and the former at night.

Antipyrin may be given in enema at the dose of 2 to 4 gr. in a drachm or two of water.

Lumbar puncture has been employed in cases of convulsions due to hypertension. Boquel tried it with success in new-born infants.

Once the seizure is relieved, the cause of the malady should be treated, and everything done to avoid a recurrence of the attacks. All cause of cerebral excitement should be removed; the digestive tract should be carefully watched; sea baths, salt, or sulphur baths should be forbidden, as well as tea, coffee, and other exciting drinks.

#### PAINFUL HÆMORRHOIDS.

Cocain, 2 gr.  
Menthol, 4 gr.  
Lanolin, 3 dr.

#### ACNE.

Sublimed sulphur, 1 dr.  
Talc, 1 dr.  
Glycerine, 2 oz.  
Tincture of quillayæ, 2 dr.  
Rose water, 4 oz.

#### ACUTE LARYNGITIS.

Menthol, 1 dr.  
Tincture of opium, 1 dr.  
Cherry laurel water, 1 oz.  
Tincture of eucalyptus, 2 oz.

A teaspoonful in a little boiling water for inhalation.

## GERMANY.

Berlin, August 29th, 1909.

THE *Deutsche Medizinische Zeitung*, No. 64/09, contains a reference to a paper by Dr. Thorkild Røvsing on the VACCINATION TREATMENT OF COLI INFECTIONS OF THE URINARY ORGANS.

The diseases caused by the bacterium coli he says are, as is known, very benign and amenable to treatment. Even pyelonephritis, which is beyond comparison the most serious form of coli infection, and often begins with symptoms of a very alarming appearance, often changes its character under the simple treatment recommended by the writer: flushing the urinary passages with 2 to 4 litres of distilled water *pro die*, combined with a catheter *à demeure*, whereby the flow of urine is continuous, and 1 gm. of salol three or four times a day. In this way the urine becomes a mildly antiseptic fluid. If recovery does not quickly follow on this line of treatment, it is on account of some complication, which prevents the free outflow of urine; a calculus, or tumour, or descent of the kidney, or narrowing of the calibre of the ureter, and the operative removal of the obstacle generally leads to rapid cure of the pyelonephritis. But a minority of cases, which the writer reckons at 15 per cent., success is not attained in this way; these are complicated cases that have not been treated early enough, or such as have had sudden relapses. In these, Røvsing has had recourse to the vaccination form of treatment founded on Wright's theory of opsones, which so far has not been much made use of in coli infections. Generally speaking, any attempts of this kind have been made with pure cultivations from the intestines of another individual, but good results can scarcely be expected in this way, as what is called the colon bacillus is only a collective name for a very numerous series of microbes of very varying degrees of virulence. The writer thought the only correct way would be to use pure cultivations made from the micro-organisms met with in the urine of the patient himself, for it was against these that treatment had to be directed. He has tried this method in 12 cases so far; in all these cases treated by this form of vaccination treatment, the symptoms all disappeared with the exception of the bacteriuria. The vaccines were prepared by taking the bacteria from an agar cultivation washed in a 0.85 per cent. saline solution, and destroyed by warming for two hours at a temperature of 60 to 65 C. For sterilisation a  $\frac{1}{2}$  per cent. carbolic solution was added. The fluid was then diluted until it contained 100 millions of bacteria to the cubic centimetre. The commencing dose for an adult was 15 millions, injected into the arm or leg.

Four cases are given which, on account of their severity, were convincing. Of course, four cases are no proof, but considering that the writer was originally prejudiced against the method altogether, and considering also his great experience in this class of diseases, it is so far an encouragement for others to give it a trial.

One question asked by those who wish to give the method a trial is: are there any special dangers associated with it? The author remarks that so far as he has seen no signs of anything objectionable from its employment. All reactions, both local and general, passed off very quickly. There was slight rise of temperature, but a quick fall without any rigor, and a slight feeling of being unwell, but without being at all pronounced, was the only indication of general reaction. He has never seen any local reaction at the point of injection with small or medium doses, but with large doses there were redness, pain, oedema, and infiltration with some slight lymphangitis—as when 1,000 millions of bacteria were injected. He believes, however, that even this may be avoided by giving the injections in divided doses. In one case only the injections were constantly followed by high temperature and alarming general symptoms. It was that of a woman, æt. 52, with calculous nephritis, in whom, after removal of the stone, considerable febrile nephritis remained. Every time after this patient received the vaccine injections the temperature rose several degrees, she became light-headed, with clonic

convulsive moments of upper and lower extremities. In the course of from 12 to 24 hours, however, these symptoms subsided completely, and she steadily improved afterwards; her urine also became clearer and freer from albumin.

Possibly the dose was too large in this case and given without regard to the opsonic index. On the whole he gained the impression that the vaccination treatment was mild and quite free from risks.

As a reminder to any who intend to make a trial of the method, he remarks that vaccination does not appear to have any marked bactericidal effect, and, that to effect the expulsion of bacteria from the urinary passages it will be advisable to combine this treatment with flushing out the urinary organs with distilled water, the catheter *à demeure*, and salol.

### AUSTRIA.

Vienna, August 29th, 1909.

#### SPUTUM DIAGNOSIS.

FALK and Tedesco recorded to the "Gesellschaft für innere Medizin" a method of diagnosis which they have confirmed in giving definite doses of salicylate of soda in the form of an oblatum. Twelve or fifteen hours later salicylic acid will be coughed up if pneumonia be present; but if acute, chronic, congestion of the bronchi, or bronchiectasis be present, no salicylic acid will be found, but pus and other products will be plentiful. In the case of pneumonia the amount of salicylic acid found will be in proportion to the intensity of the pneumonia—the more salicylic acid the more severe the pneumonia attack; with the recovery this constituent will gradually disappear. In tuberculosis salicylic acid is present, but not in the same quantity as it is to be found in pneumonia; however, in acute cases of tuberculosis the quantity is much greater than in the chronic form.

Noorden remarked that after large doses of soda salicylate he found large quantities of the acid in the joints.

#### OXYDATION AFTER HEPATIC REMOVAL.

Porges related his experiments on animals from which he had removed the liver after tying the inferior vena cava and large arteries, thus leaving the entire abdominal organs with this exception in the normal circulation. The amount of oxydation measured by expiration in the control animal was as 0.9 is to 1 in the fasting animals which represented the carbohydrate change in the muscles. Some of the experiments were as low as 0.7. When it is considered that the muscles are the only available source in a hungry animal the only reasoning left is that the albumen and fat must previously be converted into this substance by the muscles. Now, according to theory, the changes take place in the liver, which could not in this case. Embden, however, proved some time past that fatty acids in the liver were converted into acetone bodies. It is possible, however, that acetone is the intermediary product between fat and sugar, and that the liver may be the active centre of this transition. This is a theory yet to be proved. Fehling's solution reduces the acetates, but does not give the characteristic reaction of sugar, but appears to be closely allied with it. Porges further described an experiment he carried out with Dr. Salomon by extirpating the liver of a pancreatic diabetic dog where the respiration quotient was unity. This showed that the burning of sugar was not disturbed by the operation.

Noorden thought this unaltered condition of the respiratory quotient in the diabetic dog should throw more light on our treatment of diabetes in man.

#### ELECTRO-CARDIOGRAPHS.

Eppinger and Rothberger gave an explanation of the cardiographs obtained in the laboratory in testing the irritable centres of the cardia. It is not regularly distributed over the organ, as the base of the heart is almost negative. Nicolai believed there were fixed centres of excitement in the myocardia, although they might be modified by the different layers of the organ, but recent interpolating has dissipated that theory, and proved the increasing excitability increasing towards the apex. This is modified by cooling of any

part on the cardiac surface. If the surface of the left ventricle be sprayed, and a crust of ice formed, the current on this part will have a negative result; this is also true of the right ventricle. It is different, however, with the base, as the current is more active in this position than in health, although the resistance remains the same. If the heart be thawed and the muscle allowed to return to its original red condition, the reaction will be the same as at the beginning.

If the deeper parts of the heart be tested, such as the septum, a variety of results may be obtained. To perform these it is necessary to use an aqueous solution (concentrated) of sublimate or nitrate of silver, and inject 0.1 to 0.5 of a cubic centimetre to produce necrosis of the part. The result will be positive on the one side or the other, just as the pole is moved from the one side or the other. It is interesting to note that large centres of necrosis often produce negative results, while small ones are always positive; thus it is difficult to say whether the centre of irritation is more internal than external. If large necroses be produced opposite to papillary muscles of the heart, the electro curve is not altered. The trabeculae of the ventricles will determine the contraction; the left, having more circular fibres than the right, will contract in this order, while the right, having more longitudinal, will contract in its length or upwards, as experience teaches in hypertrophy and dilatation.

## LETTERS TO THE EDITOR.

[We do not hold ourselves responsible for the opinions expressed by our Correspondents.]

### THE HOME SECRETARY AND QUACK MEDICINES.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—You will, no doubt, publish a report of the question put by Captain Craig to the Home Secretary in the House of Commons, last week, and the reply it elicited. It would be easy to exaggerate the importance of this incident; easy to make too light of it. It shows, at least, that Members of Parliament are becoming alive to the facts of the fraudulent quack medicine trade, and it is satisfactory to see that these members are inclined to take up the question seriously. It is not to be imagined that Captain Craig stands alone, and will fail to gain ample support in the House, if, as may be hoped, he is determined to follow the matter up. You, Sir, are aware that I have for many years been striving to force this question upon the attention of the Legislature. It has been a depressing experience, and lately I have been taking a pessimistic view of the prospects of success. I have always held that, on humanitarian grounds alone, it has been the duty of the profession to strive to put an end to a state of things in which an army of cynical rascals is enabled to prey with impunity upon suffering humanity. The profession unfortunately possesses no political power, and no means of making its voice directly heard in Parliament. I have always held, further, that the case for legislation is overwhelming, and that laws to put an end to the worst of the abuses could be easily constructed. My pessimism is, however, now changing to optimism. If the British Medical Association will only persevere in the part in which it has lately engaged, and if you and other medical papers will continue your campaign, we must in the end obtain, by one means or the other, an exposure so full and public as shall compel the attention of Parliament. The exposure can be best made by a Royal Commission, but any Commission that does not include the quack medicine trade will be largely futile. THE MEDICAL PRESS AND CIRCULAR has already earned the thanks of medical law reformers for its persistent and consistent action in this matter during many years, and I have reason to believe that many Members of Parliament owe their knowledge of the question mainly to your paper. In continuing the work in which you have taken so valuable a part, it is desirable on occasion to keep to the front the fact that quackery, including the fraudulent nostrum traffic, is the direct cause of vast injury to the public

health. Quackery creates invalids and aggravates disease. It forms thus really a source of pecuniary gain to legitimate practitioners, into whose hands its victims sooner or later pass. If all the facts are made known, it will be impossible to impute sordid motives to the profession in this connection, or to accuse them on valid grounds of being influenced by any save philanthropic motives.

I am, Sir, yours truly,

HENRY SEWILL.

The Old Rosery, Redhill, August 28th, 1909.

[We are glad to be able to say that it is mainly due to the efforts of an old friend and supporter of THE MEDICAL PRESS AND CIRCULAR that the question referred to was put in the House, and that his request was strengthened by reference to articles in this journal.—ED. M. P. AND C.]

#### THE DECLINING BIRTH-RATE.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—I have tried to make it clear to a "Student of Sociology" that emigration, although to some degree compensatory and a temporary expedient, nevertheless as an entire scheme is, in reality, a totally inadequate means to solve the complex problem of a surplus population *plus* a declining birth-rate. May I ask, by the way, for example, whether emigration and an increasing birth-rate in Ireland have fulfilled the anticipations which your correspondent hopes for in this country?

The principle of enforced emigration at its best, which means the forcible expulsion, through unemployment, poverty, and dire necessity, of the best of our working class from their native soil, is repulsive to the great majority, who imbibe the natural instincts of their more affluent brethren and prefer to remain at home. Why, therefore, are they not at liberty to do so, and why should preparation and provision, as in other countries, not be made accordingly?

Your correspondent points to Germany, with the tantalising remark and reference to their population of 68,000,000. He may observe that the very conditions which enable that prosperous country to rear and maintain its numerous population are the very reverse to those he would land us in, because the German emigrants become less and less year by year—and why? The answer is simple—viz., they cultivate their soil. This is the keynote of their numerous population. Let us therefore follow suit as far as feasible, for it is scarcely necessary to remind your correspondent that art, science, culture, or education, however admirable from a social or civilised point of view, will not supply a community with bone and sinew—in other words, they will not produce physique (a much more valuable asset than brains at the present juncture). Let us, therefore, put forth the most strenuous efforts by hook or by crook to expand to the uttermost our agricultural resources, whereby we create constant and a never-failing source of employment. This is the only possible solution of the problem in question, and, I may add advisedly, the only means of preserving our country and Empire from inevitable decay, disintegration, and total wreck.

I am, Sir, yours truly,

CLEMENT H. SERS, M.R.C.S.

Brighton, August 27th, 1909.

#### NOSTRUMS AND INFANT MORTALITY.

To the Editor of THE MEDICAL PRESS AND CIRCULAR.

SIR,—It is a remarkable and significant fact that the newspapers, with rare exceptions, invariably publish only the briefest possible reports of coroners' inquests in which the pernicious character of the quack medicine trade is exposed, and that they invariably in such cases suppress the name of any nostrum the true qualities of which are thus laid bare. Quack medicine proprietors are the most profitable customers of most papers, and the owners cannot, from the business point of view, afford to offend them. It would be a help to medical law reformers if coroners could be induced to send reports to the medical papers of all

cases of the kind, and with their own remarks in full. An inquest was held in Southwark last week at which the coroner, Dr. Waldo, evidently made some strong observations; but these are hardly more than suggested in any of the reports that I have seen. He apparently commented, first, on the fact that a mother, instead of calling in medical advice, had dosed her dying child with "teething" powders. Next he referred to the shameful fact that the Government are deriving a "rich harvest from these secret remedies." He then elicited from the chief medical witness the fact that these remedies often contained dangerous drugs, and added for himself that they were responsible for part of the high infantile mortality. A week or two ago you reported a case in which a child died from pneumonia without medical attendance, the parents having relied throughout on a widely advertised "lung cure," the most potent ingredient of which is merely treacle. Teething medicines often contain nothing more powerful than that, and confidence in them leads to many a death. When they contain anodynes they mask the symptom of pain, mostly due to improper feeding, and lead the infant quietly towards death, or to survival as a rickety cripple. If Dr. Waldo and other coroners would speak out on occasion, and take some slight pains to make their utterances public, they might easily help to put an end to much infantile misery, whilst doing a real service to the State.

I am, Sir, yours truly,

AN OBSCURE PRACTITIONER.

August 26th, 1909.

#### OBITUARY.

RADCLIFFE CROCKER, M.D.Lond., F.R.C.P.

WE regret to announce the sudden death of Dr. Radcliffe Crocker at Engelberg, Switzerland. Besides his many appointments at the principal London skin hospitals, Dr. Crocker's fame was world-wide. He was an honorary member of the American, French, Austrian, German, and Italian Dermatological Societies, physician to the skin department of University College Hospital, and a vice-president of the British Medical Association. Dr. Crocker revised the Dermatological Catalogue which is in use at the Museum of the Royal College of Surgeons at the special request of the Council.

He was born at Brighton in 1845, and received his early education in a small private school in that town. Later, while acting as assistant in a busy practice, he passed the Matriculation and Preliminary Scientific M.B. Examinations of the University of London, and thereupon entered as a student at University College, London. At the first M.B. Examination he carried off the gold medal in Materia Medica, and at the Final M.B. in 1874 he won the University Scholarship and gold medal in Forensic Medicine. In 1887 he was elected a Fellow of the Royal College of Physicians.

After holding several appointments at University College Hospital, Charing Cross Hospital, and the Brompton Hospital, he became associated with the late Dr. Tilbury Fox, and was by him so attracted by the study of diseases of the skin that he determined to devote his life to this department of medicine. For nearly thirty years he has been Physician-in-Charge of the skin department of University College Hospital.

He was the first President of the Dermatological Section of the Royal Society of Medicine, and was an honorary member of the Dermatological Societies of America, France, Austria, Germany, and Italy. He made many valuable contributions to the literature of dermatology, but his name is especially associated with his "Treatise on Diseases of the Skin," which ran through three editions. Hardly second to it in value is his "Atlas of Diseases of the Skin," which is a fine model of a scientific work.

ROBERT GORTON COOMBE, F.R.C.S.

WE regret to announce that one who must have been almost, if not quite, the oldest London surgeon has

passed away in the person of Mr. Robert Gorton Coombe, at North Kensington.

Mr. Coombe was in his 92nd year, and for many years practised at Burnham, in Essex, before proceeding to Kensington. In the Burnham district he had been an Admiralty surgeon. He was admitted a member of the Royal College of Surgeons by examination in 1841, and in 1884 was elected by the Council to the Fellowship of the college for "professional attainments."

## SPECIAL ARTICLES.

### DEPARTMENTAL COMMITTEE ON THE MIDWIVES ACT.

THE report has just been issued of the Departmental Committee appointed in December, 1908, by the Lord President of the Privy Council, "to consider the working of the Midwives Act, 1902, and in particular with reference to the supply of midwives and the cost of training, the remuneration of medical men summoned on the advice of midwives under the rules in pursuance of the Act, and the delegation of their powers by county councils under the Act." The Committee held 21 meetings, on 12 of which they sat for the purpose of hearing evidence, and they examined 37 witnesses. Of these, 13 were ladies, including eight certificated midwives, and 18 were medical practitioners.

The introductory passages of the report express satisfaction with the working of the Act, and with the extent to which it has fulfilled the objects aimed at by its promoters.

The Committee report that the extensive powers enjoyed by the Central Midwives' Board, in spite of the experimental character and somewhat fortuitous constitution of that body, have on the whole been exercised with judgment, prudence, and sympathy, and that the experience of six years has added greatly to the good will with which the Act is appraised, both by the authentic voice of the medical profession (subject to certain reserves) and by the authorities concerned in local administration. The Committee cite evidence, statistical and other, tending to show that the operation of the Act has already effected a considerable diminution both of maternal and of infantile mortality; but they refrain from insisting upon these aspects of the question until a longer time has confirmed the impressions which are now generally entertained.

Passing on from these general considerations, the report deals next with the third point of the reference to the Committee, the question of whether it is desirable that county councils should delegate to district councils their powers under the Act. This power has not been generally exercised, and in some cases county councils have wisely revoked powers thus delegated; but in a few cases where the practice still obtains it has been found to operate detrimentally to the purposes of the Act, and to introduce elements of confusion and uncertainty into its administration. The evidence appears to be conclusive upon the point; and the Committee declare that, under conditions of extensive delegation, uniformity of aim and practice are unrealisable, while the difficulties of supply, distribution, and training are enormously augmented. They therefore recommend that the power of delegation should be withdrawn, and that, in cases where it is still exercised, the delegation should be revoked.

#### SUPPLY AND TRAINING OF MIDWIVES.

On the question of the supply of midwives and the cost of training the Committee take an entirely encouraging view of the situation; and they are unanimous in rejecting the suggestion that any postponement of that part of the Act which comes into operation on August 10th, 1910, would be expedient. To the retrograde and disastrous effects of such a step witnesses of every type and representative of every interest emphatically testified. In the opinion of Miss Rosalind Paget, who appeared on behalf of the Incorporated Midwives' Institute, and who sits on the

Midwives' Board as the nominee of Queen Victoria's Jubilee Institute, it would destroy the principal stimulus to activity upon which those engaged in organisation now rely. Miss Amy Hughes declared that "it would create chaos"; and Dr. Hope, of Liverpool, thought "it would be a great mistake." In these opinions the Committee concur. From the evidence put before them they show that, excluding Wales, "from which the figures are not complete, owing to the indifference or neglect of the parties concerned," there seem to be some 15 counties, out of 50, in which a shortage is anticipated; but they regard the question as mainly one of distribution. The problem to be solved is of a partial and sporadic character, and the Committee are impressed with the belief that the solution is to be found in intelligent and effective organisation, to which all the administrative entities interested should be expected to contribute. Successive recommendations embody a large number of practical suggestions to the councils, societies, and other bodies and individuals concerned.

#### MEDICAL FEES.

On the third point of reference, that of the remuneration of medical men summoned on the advice of midwives under the rules in pursuance of the Act, the Committee had no difficulty in recognising the existence of a very real and substantial grievance affecting the medical profession. The patient under the care of a midwife is, in the majority of cases, a person in humble circumstances; and the Act enjoins that the midwife, as soon as she recognises the existence of any difficulty or source of danger, shall call in the assistance of a medical practitioner, who is then to obtain remuneration how he can. Some remarkable evidence as to the operation of this portion of the Act was placed before the Committee by Dr. Howard Jones, Medical Officer of Health for Newport, in Monmouthshire, who had addressed a circular of inquiry to the 22 medical practitioners in his locality who had been sent for by midwives in pursuance of the Act. Replies were received from 21, but data contained in one of these replies were incomplete, and are not included. The 20 practitioners whose records are given had attended 559 such cases, or an average of 27.9 patients each. Many were difficult instrumental labours, while some were minor complaints of the mother or infant. In 279 of the cases, or 49.9 per cent. of the whole, the doctor received no payment. In 62 instances, or 11 per cent., part fees were obtained, varying from 2s. 6d. to 10s. 6d., while in 218 cases the fees were paid in full. Seven medical men with over 40 cases each attended 405, in 215 of which no fees were paid, and in 23 others part fees only. One practitioner was sent for in 123 instances, and in 58 of these no fees were paid; while another received payment in only 20 per cent. of his cases. If the fees were computed at a guinea for each case, the fees earned by medical men in Newport and not received amounted to £293 19s.; while the "notices" sent by midwives to medical men have been treated as urgent, and have been attended to without reference to payment in the great majority of cases.

In view of the facts submitted to them, the Committee were unanimously of opinion that the Act should be amended by giving the practitioner summoned by a midwife in cases of emergency a secure expectation of payment; and they suggest that the local authority charged with the administration of the Poor Law should be made responsible, and should be empowered, when it sees fit, to charge the fee paid as "relief on loan" to the patient.

#### THE DUBLIN HOSPITALS.

THE Annual Report of the Board of Superintendence of the Dublin Hospitals (a) was presented to Parliament last week. The title of the Board is somewhat misleading, as it is not by any means charged with the superintendence of the Dublin hospitals in general, but only of those in receipt of Government grants.

(a) Fifty-first Annual Report of the Board of Superintendence of the Dublin Hospitals, with Appendices, for the year 1908-09. Dublin: H.M. Stationery Office, 1909.

These are nine in number—viz., three general hospitals, Dr. Steevens', the Meath, and the House of Industry; two maternities, the Rotunda and the Coombe; and four special hospitals, the Westmorland Lock, Cork Street Fever, Royal Victoria Eye and Ear, and the Royal Hospital for Incurables. Of these the Westmorland Lock Hospital is practically supported by its grant, and the House of Industry Hospitals derive the greater part of their income (£7,600 out of £11,036) from the same source. The grants to the other hospitals vary greatly, Cork Street receiving £2,500, Steevens' £1,300, the Rotunda £700, the Meath £600, the Royal Hospital for Incurables £250, the Coombe £200, and the Royal Victoria Eye and Ear £100. The grants, of course, have not any special relation to the scope or activity of the respective hospitals, and, indeed, are not planned on any system. They have been given at various times, and practically are not subjected to revision.

High praise is given by the Board to the general management of all the hospitals supervised. As far as the care of the sick in the wards is concerned, it is admirable. As regards the out-patient departments, however, the same level of excellence is not reached, the failure being due to lack of funds.

"To this part of the hospital," the Report runs, "two classes of patients come, those seeking admission into hospital, and those wanting only such treatment as can be given to them on the spot, or which can be carried out in their own homes. These are, as a rule, a most deserving class—persons anxious to remain at work, 'to be kept on their legs,' and to be on the rates as light a burden as circumstances will allow. A question that insists on presenting itself to us is this: Was the treatment of these patients all that could be desired? Was it on a level with what the patients in the wards were receiving—i.e., on a level with the ideas of the present time? We think not. The day is gone when it was thought that a bottle of medicine, however cleverly prescribed, satisfied the requirements of the majority of cases. The great improvements in hospital efficiency, in the way of meeting the requirements of the situation, the cleanliness and even elegance so noticeable in the wards, and which, for many poor souls, make a brief stay in hospital an advance in civilisation as well as in health, have not in anything like the same degree been extended to the out-patient department. At the same time we attach no blame to the various hospital authorities. The state of the intern departments is proof of their capabilities and goodwill, and had they funds no doubt all parts of the institutions under their control would be on an equal level. However, this question of dispensary practice and what is necessary to bring it to an ideal standard is so important, especially now there is question of poor-law medical reform, that we cannot pass it by in silence. It cannot be expected that dispensaries throughout the country will be worked in a fashion superior to that of the educational hospitals of the metropolis. With more funds and more co-ordination much might be done."

A comparison of the items of expenditure in the different hospitals reveals some curious contrasts. For instance, taking the item of cost of stimulants, we find that the Westmorland Lock Hospital, with an average of 57 beds occupied, spends only £1 per annum; Dr. Steevens', with 112 beds, spends £77 17s. 6d.; the Rotunda, with 91 beds, spends £3 8s. 5d. Again, the average annual cost per bed for maintenance varies from £12 1s. in the Royal Hospital for Incurables, and £15 in the House of Industry, to £20 15s. in the Meath, and £21 10s. in Dr. Steevens'. It is difficult to see why the cost of maintenance in the two latter hospitals is so much greater than in the House of Industry, a similar institution.

Appendices give particulars of the diseases treated and the operations performed in each of the hospitals.

THE International Medical Congress was opened at Buda-Pesth on August 30th with great ceremony by the Archduke Franz Joseph, who in his inaugural address dwelt on the immense services rendered by the medical profession, through individuals, to humanity as a whole.

## REVIEWS OF BOOKS.

### TUBERCULIN IN DIAGNOSIS AND TREATMENT. (a)

PROGRESS in the campaign against tuberculosis is hampered by two great difficulties, for which some solution must be found if any very considerable progress is to be made. These are, first, the very great difficulty in making a definite yet early diagnosis in cases of pulmonary tuberculosis, and, secondly, the absence of any satisfactory method of specific treatment. By early diagnosis we mean the diagnosis of a case where infection of the lungs has taken place, but where the anatomical changes are not sufficient to produce evident or demonstrable physical signs. It is while in this condition that the cure of patients may be undertaken most hopefully, but treatment is hampered by the impossibility of demonstrating the correctness of the diagnosis unless the condition of the patient becomes worse, while if one waits for the time when a positive diagnosis can be made, the time for successful treatment has too often passed. The very nature of the treatment, too, adds to the difficulty. Among the poorer wage-earners one hesitates to enforce the restrictions necessary for treatment without a positive assurance of the necessity for doing so. Then, even if the treatment is successful, and the disease arrested, there is no guarantee that the patient is not as susceptible to infection after as before the treatment. It would seem, then, that what is needed is some method of making an early yet positive diagnosis, and some method of treatment that will not only arrest the disease, but lessen the liability to subsequent infection, and a method, too, which can be employed without cutting off the patient from the means of earning his livelihood. Both these methods, if they are to be of real use, must be such as can be employed by the ordinary general practitioner. We are firmly convinced that the stamping out of tuberculosis, if it is ever accomplished, will be accomplished by the general practitioner, and not by the specialist or by special institutions.

Evidence seems to be rapidly accumulating that in the use of tuberculin such desirable methods will be found, and in the book before us an admirable review of this evidence is given. Drs. Bandelier and Roepke have not, however, remained satisfied with a review of the evidence, but have given us most elaborate yet clear instructions of how to use the methods and so accumulate evidence for ourselves. Our own experience agrees with that of our authors, and though we are not in a position to say that the case is proved, we feel the utmost confidence in the future. As regards the work before us we have nothing but praise. The instructions are simple, yet definite and practical; the facts, so far as they are known, are clearly stated, and the inferences are logically and temperately drawn. We would wish to see this book in the hands of every medical practitioner, and the methods recommended in it adopted as a regular part of his practice. We then might look forward with more hope to a successful issue in the near future of the campaign against tuberculosis. Our thanks are due also to Dr. Morland for his admirable translation of what we consider a most valuable work.

### A SYSTEM OF MEDICINE. (b)

THE present volume of this well-known System of Medicine deals with the same subjects as did the corresponding volume in the original edition, but has

(a) "Tuberculin in Diagnosis and Treatment." A Text-Book of the Specific Diagnosis and Therapy of Tuberculosis for Practitioners and Students. By Dr. Bandelier and Dr. Roepke. Translated from the Second German Edition by Egbert C. Morland, M.B.Lond., M.D.Berne. London: John Bale, Sons, and Danielsson.

(b) "A System of Medicine by Many Writers." Edited by Sir Clifford Allbutt, K.C.B., M.D., LL.D., F.R.C.P., F.R.S.Edin., Regius Professor of Physic in the University of Cambridge; and Humphrey Davy Rolleston, M.D., F.R.C.P., Senior Physician to St. George's Hospital, Physician to the Victoria Hospital for Children. Vol. v., Diseases of the Respiratory System. Disorders of the Blood. Pp. xii and 969. London: Macmillan and Co.

undergone very considerable modification. Amongst the principal changes which have been made are the following:—The article on acute lobar pneumonia and broncho-pneumonia has been re-written by Drs. Beddard and Eyre. The articles on lobar pneumonia and on chronic interstitial pneumonia have been revised by Drs. Beddard and Eyre and Dr. Fawcett respectively. Sir John Oliver has re-written the article on pneumoconiosis. Dr. Perkins has written new articles on new growths of the bronchi and on abscess and gangrene of the lung. The article on pleurisy has been revised by Dr. Horder, and Dr. Bosanquet has dealt with the diseases of the thymus gland.

The articles on pernicious anæmia, splenic anæmia, and hæmophilia have been re-written respectively by Dr. French, Drs. Hutchinson and Ledingham, and Sir Almroth Wright. New articles on polycythæmia and erythræmia, and on cyanosis have been contributed by Dr. Parkes Weber and by Dr. Garrod.

The volume consists of four parts. The first deals with diseases of the lungs, the second with diseases of the pleura, the third with the diseases of the mediastinum and thymus, and the fourth with disorders of the blood.

We congratulate the Editors on the admirable manner in which they have accomplished the task of revision, and on the distinguished contributors whose services they have obtained. The completion of their task is now within view, as only three volumes of the original edition remain unrevised.

### NEW BOOKS AND NEW EDITIONS.

The following have been received for review since the publication of our last monthly list:—

**BAILLIÈRE, TINDALL AND COX (London).**

- Surgical Anæsthesia.* By H. Bellamy Gardner, M.R.C.S., L.R.C.P.Lond. Pp. 240. Price 5s. net.  
*Diseases of the Throat, Nose, and Ear, for Senior Students.* By Wm. Lamb, M.D., C.M., M.R.C.P.Lond. Second Edition. Pp. 340, 55 illustrations and 2 plates. Price 7s. 6d.  
*Aids to the Analysis of Food and Drugs.* By O. G. Moor, M.A. Cantab., F.I.C., and William Partridge, F.I.C. Third Edition. Pp. 249. Price, cloth, 3s. 6d. net.  
*Aids to the Mathematics of Hygiene.* By Bruce Ferguson, M.A., M.D., B.C., etc. Fourth Edition. Pp. 162. Price 2s. 6d. net.

**JOHN BALE, SONS AND DANIELSSON, LTD. (London).**

- The Dental Directory, 1909.* Compiled from Official Sources. Pp. 248. Price 2s. 6d. net.  
*Synoptic Chart of Cardiac Examination.* Arranged by John D. Comrie, M.A., M.Sc., M.B., F.R.C.P.E. Price 2s. 6d. net.  
*The Campaign against Microbes.* By Etienne Burnet, M.D. Translated from the French by E. E. Austen, F.Z.S. Pp. 248. Price 5s. net.  
*Adenoids, Nocturnal Enuresis and the Thyroid Gland.* By Leonard Williams, M.D., M.R.C.P. Pp. 31.

**BOOTHROYD, ELIOT (London).**

- Low's Handbook to the Charities of London, 1909.* Pp. 248. Price 1s.

**CHURCHILL, J. and A. (London).**

- Report on Plague in the Gold Coast in 1908.* By W. J. Simpson, M.D., C.M.G., etc. Pp. 55. Price 2s. net.  
*An Atlas of Dental Extractions, with Notes on the Causes and Relief of Dental Pain.* By O. Edward Wallis, M.R.C.S., L.R.C.P., L.D.S. Price 3s. 6d. net.

**A. C. FRIELED (London).**

- The Poor Law Commission and the Medical Profession.* By A Medical Practitioner. Pp. 16. Price 1d.

**HENRY FROWDE (London).**

- The Treatment of Disease.* By Wm. Osler, M.D., F.R.S. Pp. 26. Price 1s. net.

**HENRY FROWDE AND HODDER AND STOUGHTON (London).**

- The Oxford Medical Publications. A System of Medicine.* Edited by William Osler, M.D., F.R.S., assisted by Thomas McCrae, M.D., F.R.C.P.Lond. Volume VI. Pp. 799. Price 30s. net per volume, or to subscribers 24s. net per volume.  
*Oxford Medical Publications. The Blood in Health and Disease.* By E. J. M. Buchanan, M.D., F.R.C.P. Pp. 318. Price 12s. 6d. net.  
*Oxford Medical Publications. A System of Operative Surgery.* By Various Authors. Edited by F. F. Burghard, M.S.Lond., F.R.C.S.Eng. In Four Volumes. Vol. IV. Pp. 687. Price 36s. net per volume; to subscribers, 26 net per set of four volumes.

**H. J. GLAISHER (London).**

- Lectures on Hysteria and Allied Vaso-Motor Conditions.* By T. D. Savill, M.D.Lond. Pp. 262. Price 7s. 6d. net.

**GREEN, WILLIAM AND SONS (Edinburgh and London).**

- A Theory Regarding the Origin of Cancer.* By C. E. Green. Second edition. Pp. 46.

*A Handbook of Diseases of the Nose and Throat.* By Eugene S. Yonge, M.D.Edin. Pp. 407.

**H. R. LEWIS (London).**

*Immunity and Specific Therapy.* By W. D'Este Emery, M.D., B.Sc.Lond. Illustrated. Pp. 448. Price 12s. 6d. net.

**E. AND S. LIVINGSTONE (Edinburgh).**

*Medical Fellowship, D.P.H., and Dental Examination Papers.* Pp. 288. Price 1s. 6d. net.

**MACLEHOSE, JAMES, AND SONS (Glasgow).**

*Clinical Manual for the Study of Diseases of the Throat.* By James Walker Downie, M.B., F.F.P.S.G. Second edition, revised and in large measure rewritten. Pp. 432. Price 10s. net.

**MOFFATT, YARD AND CO. (New York).**

*Tuberculosis: A Preventive and Curable Disease. Modern Methods for the Solution of the Tuberculosis Problem.* By S. Adolphus Knopf, M.D. Pp. 304. Price \$2.00 net.

**MORGAN AND SCOTT (London).**

*An Appeal on Behalf of the Government and People of China.* By H. E. T'ang K'ai Sun. Pp. 32. Price 3d.

**JOHN MURRAY (London).**

*Children in Health and Disease: A Study of Child-Life.* By David Forsyth, M.D., D.Sc. Pp. 362. Price 10s. 6d. net.

**THE PANINI OFFICE (Allahabad).**

*The Dietetic Treatment of Diabetes.* By B. D. Basu. Pp. 40. Price Rs.1.8.0.

**REEMAN, LTD. (London).**

*The Maniac. A Realistic Study of Madness from the Maniac's Point of View.* Pp. 304. Price 6s.

**W. B. SAUNDERS CO. (Philadelphia).**

*Myomata of the Uterus.* By Howard A. Kelly, M.D., and Thos. S. Cullen, M.B. Illustrated. Pp. 723. Price 35s. net.

**JOHN WRIGHT AND SONS, LTD. (Bristol).**

*Questions on Sick Nursing and Home Hygiene.* By D. M. Macdonald, M.D. Pp. 34. Price 6d. net.

## MEDICAL NEWS IN BRIEF.

### Quack Medicines.

THE following question by Captain Craig is contained in the Parliamentary papers: To ask the Home Secretary whether his attention has been called to the increase in recent years of the sale of quack medicines; whether he is aware that it has been proved that such nostrums frequently contain nothing but harmless drugs, coloured grease, coloured water, small quantities of aloes, pilules of sugar, etc., though advertised to cure a multitude of different maladies; whether he is aware that the chief cost of such quack medicines is in the advertising; and whether he will appoint a small Commission to inquire into and report upon the whole subject.

Mr. Gladstone: I beg to refer the hon. member to the answer on this subject which I gave to the hon. member for North Lambeth on March 12th last. I understand that inquiries are being made, at the instance of the Lord President of the Council, as to whether the practice of medicine by unqualified persons is extending, and as to the effects produced by such practice. These inquiries will no doubt throw some light on the question of the use of quack medicines, and I think it will be advisable to await their result.

### The Cholera at Rotterdam.

ON August 26th the Mayor of Rotterdam made a reassuring statement in the Town Council with regard to the outbreak of cholera. No further deaths have occurred, but over 40 people were then under observation. It is supposed that the cholera was caused by infected ballast or tank-water taken in by timber ships at Riga, St. Petersburg, or Kronstadt, and discharged by them at the mouth of the Meuse before being disinfected at the port of Rotterdam.—*Times*.

Since the above report fresh cases have appeared. Special precautions against the introduction of cholera are being taken by the Medical Officer at Hull. A notice was issued on August 25th stating that all tourists and passengers arriving from Rotterdam would be medically examined.

### Jury and Sale of Poison.

AT the Clerkenwell Coroner's Court, on August 26th, Mr. Walter Schroder held an inquiry concerning the death of a plumber's labourer, who committed suicide on August 23rd by taking salts of lemon.

Evidence was given to the effect that the deceased

was very much depressed because the woman he had been living with had gone away and left him.

A daughter, æt. 14, said that the deceased on Monday afternoon told her that he was going to poison himself, and showed her a packet of salts, labelled "poison." Later she found him mixing something in a cup. She asked him what it was, and he told her that it was an egg. She tried to take it away from him, but he ran round the table and drank it. Then he sat down on a chair and groaned, and the witness called for assistance.

The jury returned a verdict of "Suicide whilst of unsound mind," and expressed the opinion that further restrictions should be placed upon the sale of salts of lemon.

#### Medical Examination of School Children.

A LARGELY attended meeting of the Glasgow and West of Scotland Branch of the British Medical Association and medical practitioners resident in Glasgow and district was recently held in the Faculty Hall, Glasgow, to consider the terms of appointment of the school medical officers in Glasgow under the Glasgow School Board. Dr. J. Grant Andrew presided. A resolution was unanimously adopted to the effect that:—

"It was agreed to advise the medical profession in Glasgow to adhere to the finding of the Association, which is expressed as follows:—That the commencing salary of the whole time school medical officer be not less than £500 per annum, and that for junior or assistant school medical officers £250 per annum (these sums to be understood as exclusive of travelling expenses, clerical assistance, cost of stationery, postages, etc.); and for part time officers the Association recommends a system of payment which is in operation in London—viz., that the salary should be based upon the time devoted to the work, and that the minimum should be £50 per annum in respect of each school session of two hours per week."

It was stated that the salaries as at present offered to quarter time medical officers by the Glasgow School Board fell far short of the recommendation of the British Medical Association and the salaries given by other School Boards to their part time medical officers. An influential committee was appointed to confer with the School Board on this matter.

It may be explained that the schedule of the terms and conditions of the appointments issued by the School Board to applicants states that the chief medical officer, whose whole time must be devoted to the duties of the office, is to receive a salary of £500 per annum. The part time appointments, for which both men and women are eligible as candidates, provided they are duly qualified and registered practitioners, are to be for 20 weeks only, for which a payment of £40 will be made, three school periods (7½ hours) to be devoted to the work.

#### Death under Anæsthetics—West Bromwich Hospital Case.

AN inquest was held at West Bromwich, on August 23rd, by Mr. J. Clark (Borough Coroner) relative to the death of Jacob Moss (47), formerly residing in High Street, Langley, who died while under an anæsthetic at West Bromwich District Hospital. He was a perfectly healthy man. He entered the hospital for removal of an eyeball, and it was arranged to perform the operation. He was examined by Dr. Turnbull, the house surgeon, who found no indications that it would not be quite safe to put him under an anæsthetic.

Dr. Sharpe, the assistant house surgeon, who administered chloroform, said the man seemed to be going under it in a normal manner when he suddenly began to struggle violently. When this ceased and the re-administration of the chloroform began, he almost immediately collapsed. Dr. Young, who was to perform the operation, and the witness endeavoured to restore animation, but without success, and he expired in a few seconds.

Dr. Turnbull, House Surgeon at the hospital, who made a post-mortem examination of the body, said the only thing he could find to account for the man's death was slight fatty degeneration of the heart. In his opinion death was due to heart failure caused by

exhaustion due to the patient's struggling under the influence of the chloroform.

The jury returned a verdict in accordance with the medical evidence, and expressed the opinion that all proper and necessary precautions were taken by the hospital staff.

#### Patients and Pauper Attire.

DR. E. CLAUDE TAYLOR, the Medical Officer of the Hampstead Workhouse, at a meeting of the Hampstead Board of Guardians last week, presented a report, in which he stated that, in regard to a certain class of patients in the observation wards, the compulsory wearing of workhouse attire militates against their recovery. This he had found was particularly so with females of the educated class, who are at times brought in on account of urgent mental trouble, but who would not, on any other ground, be classed as paupers. He suggested, therefore, that in any case where, in his opinion, this rule is prejudicial to the patient, he might direct that the patient's private clothing (of course, of a plain character only) be supplied for wear while the patient is up.

#### An Ode for the International Peace Congress.

OUR *confrère*, Dr. Macnaughton-Jones, having been invited by the President as Medical Representative of the Irish Association (in London) at the Congress being held at Stockholm this week, has composed the following ode, to be read in his unavoidable absence:—

"To raise aloft the lamp of all-pervading peace,  
And with its rays to light the path that He foretold  
Of that goodwill 'mongst men, when senseless strife  
should cease,  
And nations hate, that owes its cursed rise to greed  
of gold,  
Or through the jealous passions roused by rival claim  
To some bare strip of envied soil; to stem the tide  
Of ruthless lust for neighbours' blood—be this your  
aim.  
Nor halt because of those who would such hopes  
deride.

That man may yet above incensate thirst for blood  
And brutal passion rise, were surely nobler goal  
Than usage of his mental powers in wasteful feud.  
Is this the final message to the human soul—  
Distrust, suspicion, all that lying tongues can do  
To fan the lurid flame of war for selfish ends,  
And thus with rashness wild its own destruction woo?  
To compass this, its aid, the march of science lends.

In death and want, despair's unmeasured depths, and  
grief  
Too deep for words, we see the offspring weird of war.  
To win in such a cause and thus to bring relief  
To overburdened millions of the race were far  
The noblest task to set the human mind to solve.

There are who preach the use and worth of war and  
tell

Us that it teaches duty's claim and high resolve!  
Is there no other road save through the gates of Hell?  
By which this sacrifice of self or life we reach,  
Were that the highest price of Duty's stern demand?

Not thus does all the past of human story teach  
Through unrequited deed in every clime and land,  
That has its lasting record on the scroll of time,  
When Conscience cried for faith or Freedom raised  
her voice.

And *that* the world will ever hold the meanest crime  
(Nor deem there's left to man or nation other choice  
Than to resist should this clear issue be in sight)  
The cowardly yielding up a cause that has its claim  
Before ought else in Reason, Justice, Truth, and Right.

To bring all these to bear by friendly act—prevent  
The hostile move that leads to war, and bar the way  
To future strife, invasion's scare, is the intent  
And purpose noble of the guests who meet to-day  
On Northern soil, in Sweden's Scandinavian town;  
That ancient city on the isles, and welcomed there,  
The very fount of chivalry and past renown;  
This greeting Ireland sends and every wish that's fair.

H. MACNAUGHTON-JONES.

## NOTICES TO CORRESPONDENTS, &c.

OUR CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *Distinctive Signature or Initial*, and to avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," etc. Much confusion will be spared by attention to this rule.

### SUBSCRIPTIONS.

SUBSCRIPTIONS may commence at any date, but the two volumes each year begin on January 1st and July 1st respectively. Terms per annum, 21s.; post free at home or abroad. Foreign subscriptions must be paid in advance. For India, Messrs. Thacker, Spink and Co., of Calcutta, are our officially-appointed agents. Indian subscriptions are Rs. 15.12. Messrs. Dawson and Sons are our special agents for Canada.

### ADVERTISEMENTS.

For ONE INSERTION:—Whole Page, £5; Half Page, £3 10s.; Quarter Page, £1 5s.; One-eighth, 12s. 6d. The following reductions are made for a series:—Whole Page, 13 insertions, at £3 10s.; 26 at £3 3s.; 52 insertions at £3, and pro rata for smaller spaces. Small announcements of Practices, Assistances, Vacancies, Books, &c.—Seven lines or under (70 words), 4s. 6d. per insertion; 6d. per line beyond.

OPHTHALMOLOGIST (Exeter).—The importance of the newly-founded Congress of Ophthalmology at Oxford is obvious. If desirous of membership, you should communicate with one of the Honorary Secretaries. We imagine the fact that you are engaged in general practice should prove no bar to membership, providing you take special interest in diseases of the eye.

DR. J. O. (London).—Your valuable monograph evidently represents an enormous amount of research and observation. In its present form, however, it is unfit for publication in our columns. We will carefully consider both the possibility and the advisability of presenting it in a more condensed form, and will communicate with you later.

MATRON (Bournemouth).—The remedies you mention are all simple and efficacious. We should advise great caution, however, in dealing with nurse's ailments, as we have known most serious results from the early mismanagement of acute attacks.

T. A. L. (Leitrim).—Your view is undoubtedly the correct one. A number of journals and magazines exist only by the advertisements of quacks. As the latter extort monies from the credulous by false pretences they are committing a legal offence, while editors who aid and abet them in their wrongdoing become accessories. When the police can be induced to recognise and act upon this remorseless logic we shall see the first effective blow struck against the enormous evil of the quack medicine trade. The wealthiest and best known journals are often the greatest offenders.

## Appointments.

BAKER, M. W., B.A., B.C.Cantab., M.R.C.S., L.R.C.P., Resident House Physician to St. Thomas's Hospital, London.  
BROADBENT, F., M.R.C.S., L.R.C.P., District Medical Officer of the Newark Union.  
BUDD, A., M.B., B.S., Medical Officer of Health of the Borough of Launceston.  
BURRELL, L. S. T., M.A.Cantab., M.R.C.S., L.R.C.P., Resident House Physician to St. Thomas's Hospital, London.  
COX, R., B.A., B.C.Cantab., M.R.C.S., L.R.C.P., Resident House Surgeon to St. Thomas's Hospital, London.  
FYFFE, E. L., M.R.C.S., L.R.C.P., Junior Obstetric House Physician to St. Thomas's Hospital, London.  
GARRETT, R. R., M.R.C.S., L.R.C.P., District Medical Officer of the South Stoneham Union.  
HALLOWES, K. R. C., M.B., B.S.Dub., Certifying Factory Surgeon for the Bellanagh District, co. Cavan.  
HIGGINS, T. S., M.R.C.S., L.R.C.P., Assistant Medical Officer of Health, City of Birmingham.  
HARMENS, W., B.A., B.C.Cantab., M.R.C.S., L.R.C.P., Resident House Surgeon to St. Thomas's Hospital, London.  
HARPER, P. T., M.R.C.S., L.R.C.P., Senior Obstetric House Physician to St. Thomas's Hospital, London.  
LLOYD, Brinley L., M.B., B.S.Lond., Medical Inspector of Schools at Sheffield.  
MACKAY, D. Matheson, M.D., C.M.Edin., M.R.C.S.Eng., L.R.C.P. Lond., Honorary Assistant Ophthalmic Surgeon to the Hull Royal Infirmary.  
MCDONALD, J. M.B., C.M.Edin., District and Workhouse Medical Officer of the Belford Union.  
MENNELL, J. B., M.A., M.B., B.C.Cantab., M.R.C.S., L.R.C.P., Resident House Surgeon to St. Thomas's Hospital, London.  
PERRY, L. B., B.A., B.C.Cantab., M.R.C.S., L.R.C.P., Resident House Physician to St. Thomas's Hospital, London.  
PARSONS-SMITH, E. M., M.R.C.S., L.R.C.P., Ophthalmic House Surgeon to St. Thomas's Hospital, London.  
RUSSELL, R. F., M.B., Ch.B.Aberd., Certifying Factory Surgeon for the Ollaberry District, co. Zetland.  
SCALES, F. Shillington, M.D., B.C.Cantab., Honorary Medical Officer in Charge of the Electrical Department at Addenbrooke's Hospital, Cambridge.  
THORNTON, G. E., M.A., M.B., B.Ch.Oxon., Resident House Physician to St. Thomas's Hospital, London.  
WAINWRIGHT, G. B., B.A.Cantab., M.R.C.S., L.R.C.P., Resident House Surgeon to St. Thomas's Hospital, London.  
WILSON, H. B., B.A.Cantab., M.R.C.S., L.R.C.P., Resident House Physician to St. Thomas's Hospital, London.  
WYNN, FREDERICK E., M.B., M.Ch.Dub., Medical Officer to the Borough of Leigh, Lancashire, at a salary of £400 per annum.

## Vacancies.

Royal College of Surgeons, Ireland.—Professorship of Anatomy. Election October 7th. Applications to the Registrar. (See advt.)  
Oldham Union.—Resident Medical Officer. Salary £150 per annum, with rations, furnished house, washing, and attendance. Applications to Horace A. Quarby, Clerk to the Guardians, Union Clerk's Office, Rochdale Road, Oldham.  
Southwark Union, London.—Assistant Medical Officer at their Infirmary, East Dulwich Grove, S.E. Salary £100 per annum, with board, lodging, and washing. Applications to Sydney Wood, Clerk, Union Office, John Street West, Blackfriars, S.E.  
Leeds Public Dispensary.—Junior Resident Medical Officer. Salary £100 per annum, with board and lodging. Applications to the Secretary of the Faculty, Public Dispensary, North Street, Leeds.  
Dewsbury and District General Infirmary.—House Surgeon. Salary £100 per annum, with board, residence, and laundry. Applications to Edward Hemingway, Secretary.  
Great Yarmouth Hospital.—House Surgeon. Salary £100 per annum, with board, lodging, and washing. Applications to Richard F. E. Ferrier, Hon. Secretary, 35, Hall Plain, Great Yarmouth.  
Nottingham General Dispensary.—Two Assistant Resident Surgeons. Salary £160 each per annum, with apartments, attendance, light, and fuel. Applications to C. Cheesman, Secretary, 12, Low Pavement, Nottingham.  
Yorks Dispensary.—Resident Medical Officer. Salary £130 a year, with board, lodging, and attendance. Applications to Dr. Swanson, The Pleasaunce, Heworth, York.  
Parish of Bermondsey.—Second Assistant Medical Officer, Infirmary and Casual Wards, Lower Road, Rotherhithe, S.E. Salary £100 per annum, with rations, washing, furnished apartments, and attendance. Applications to E. Pitts Fenton, Clerk, 283, Tooley Street, S.E.  
Wolverhampton and Staffordshire General Hospital.—Resident Surgical Officer. Salary £125 per annum, with board, lodging, and laundry. Applications to J. Stephen Neil, House Governor and Secretary.  
Queen's Hospital for Children, Hackney Road, Bethnal Green, E.—Resident Medical Officer. Salary £100 per annum, with board, residence, and washing. Applications to the Secretary.  
Ashton-under-Lyne Union.—Assistant Medical Officer. Salary £100 per annum, together with rations, laundry, and residence. Applications to G. H. Partington, Clerk to the Guardians, Poor-Law Office, Ashton-under-Lyne.  
School Board of Glasgow (Medical Examination of School Children).—Chief Medical Officer. Salary £500 per annum. Applications to J. Clark, Clerk to the Board, School Board Office, 123, Bath Street, Glasgow.

## Births.

ALDRED.—On August 24th, at Lanbevor, Wroxham, the wife of Wilfrid A. Aldred, M.R.C.S., of a daughter.  
ELLIS.—On August 24th, at 208, London Road, Leicester, the wife of L. Erasmus Ellis, M.D., of a daughter.  
FOSTER.—On Aug. 26th, at Woodgate House, Wimbledon, the wife of Arthur L. Foster, Royal Army Medical Corps (nee Summerhays) of a son.  
PAIN.—On August 26th, at Montagu House, Leatherhead, the wife of Basil H. Pain, M.B., M.R.C.S., of a daughter.  
SMITH.—On August 24th, at 31, London Road, St. Albans, the wife of James Johnston Smith, M.B., Ch.B., of a daughter.  
STAMM.—On Aug. 27th at 43 High Road, Streatham, the wife of Louis Edward Stamm, M.D., of a son.

## Marriages.

BRENNER-CADBURY.—On August 25th, at St. Barnabas' Church, Bethnal Green, London, Frederick Perthes, Brenner, M.B., C.M., of 12, Lower Clapton Road, son of William Brenner, of Barrie, Ontario, Canada, to Agnes Elsie, daughter of the late Henry Cadbury, of Birmingham.  
ROWLANDS-BARNESLEY.—On Aug. 28th, at Sandon Road Wesleyan Church, David R. Rowlands, M.D., C.M., F.R.C.S.E., D.P.H.Lond., to Mabel Lillian, elder daughter of Edward W. Barnesley, Pimbury, Edgbaston.  
SHEARD-WYATT.—On August 16th, at St. Paul's Church, Cliftonville, Margate, Dr. W. F. Sheard, of Putney, son of the late Rev. W. D. Sheard, M.A., Cantab., to Jeanie Watt, adopted daughter of the late Joshua Taylor, of Putney.

## Deaths.

BOWES.—On August 27th, at East Hill House, Herne Bay, John Bowes, M.R.C.S.Eng., L.R.C.P.Lond., age 75.  
BOYD WALLIS.—On August 25, at 21, St. James's Road, Wandsworth Common, London, Charles James Boyd Wallis, L.D.S., R.C.S.Eng., in his 64th year.  
CROCKER.—On August 22nd, at Engelberg, Switzerland, Henry Radcliffe Crocker, M.D., F.R.C.P., of 112, Harley Street, London, and Bransridge, Bucks.  
FERGUSON.—On August 27th, at Loftus House, Broughty Ferry, James Maxwell Ferguson, M.D., sometime of Port Maria, Jamaica, in his 92nd year.  
GRANGER.—On August 22nd, suddenly, at a nursing home, Leeds (of appendicitis), Harry Maxwell Granger, M.B., Ch.B., aged 23, youngest son of the late Dr. John Ross Granger, of Glasgow.  
HOOPER.—On Aug. 25th at 19 Midvale Road, St. Helier, Jersey, Lucas George Hooper, A.M.D., aged 77. Deeply regretted.

No. 10.

## NOTES AND COMMENTS.

**A Scotch Diploma in English Practice.** FOR many years the qualifications of the Scotch Colleges have been popular amongst the English and Irish. At one time the standards of examination were somewhat less exacting than those of England and Ireland, but nowadays all that is changed. Then came the time when the triple qualification was created by the merging of the diploma of Edinburgh and that of Glasgow into the triple qualification of L.R.S.Edin., L.F.P.Glas. Within the past year or two, however, the popularity of the qualification has distinctly waned. The cause is not far to seek, and arises mainly from the short-sightedness of the Colleges concerned. The root of the matter is that the medical man who starts practice in England with a licentiate or triple qualification finds himself seriously handicapped in the struggle with competitors, the majority of whom hold the membership of the Royal College of Surgeons of England. The mischief is emphasised by the fact that in some mysterious way the public generally have come to the conclusion that the one diploma is inferior to the other. The question anyone purposing to practice in England will ask himself in future is whether it is worth his while to go to Scotland for his education, and for a qualification that will not furnish the most advantageous equipment for his life work? The attractions of the Edinburgh teaching will be probably outweighed in his mind by the lesser value of a licentiateship qualification when compared with a membership.

**The Scotch Colleges and their Diplomates.** THE point was pressed upon the Council of the Edinburgh Royal College of Surgeons some years ago by the Association of Medical Diplomates of Scotland, but an unfavourable answer was returned to their formal petition for the creation of a membership diploma. In this refusal we fear the College committed a great mistake in policy. There would probably have been little difficulty in effecting the desired change, for, as pointed out recently by a correspondent in THE MEDICAL PRESS AND CIRCULAR, the Medical Act of 1856 expressly refers to the members and Fellows of the Royal College of Surgeons of Edinburgh. The indifference to the interests of its diplomates thus shown by the Council can hardly fail to react adversely upon the future advent of students. The Council, adhering to the selfish and worm-eaten traditions that govern the sister English Colleges, keep their government in the grip of the higher diplomates, to the exclusion of licentiates. The rôle of the licentiate is simply to pay his fees to the Registrar, and thenceforth he is dead, so far as the

Council is concerned, unless, indeed, he commits some gross breach of social or professional law. It is not yet too late for the Edinburgh College of Surgeons to listen to the voice of reason, which has partially prevailed in the Glasgow College.

**Sir Henry Burdett and the Anti-vivisection Hospital.** LAST week philanthropic London was startled by the announcement that the Hospital Sunday grant of £95 had been rejected by the Anti-vivisection Hospital. As readers may remember, the grant was made only after public protest at the Mansion House and elsewhere by the excluded hospital. The reasons for the rejection of the grant are rendered apparent by a correspondence that has been going on between the secretary of the hospital and Sir Henry Burdett. We are bound to say that, considering the terms in which the grant was made and the attitude and language of Sir Henry Burdett, no self-respecting public body could have done otherwise than reject patronage bestowed in so offensive a manner. The principles involved in the whole proceeding are so important to the public and to the medical charities, that it is desirable to examine somewhat more closely the details of the present sorry squabble. First of all, we may disclaim all sympathy of any kind with the methods of the Anti-vivisection Hospital. The faith they profess is to us abhorrent, stupid, injurious, and logically indefensible. But, for all that, they have their rights as representing a section of medical opinion that is permitted by the State legally to put in practice its particular views—however grotesque and repulsive they may be to followers of orthodox medicine.

**The Terms of the Concession.** SIR HENRY BURDETT clearly shares our views as regards the utter foolishness and worthlessness of the anti-vivisection creed. But he has done much more than that, for he has not hesitated to plead justification for the extremely harsh words, "pretentious humbug," applied by himself to the hospital methods at a public meeting. Now, what Sir Henry thinks in his own mind is one thing, and what he says in public as a leading spirit in the Hospital Sunday Fund is another. As things stand, it must be inferred that Sir Henry Burdett is the official spokesman for the Metropolitan Sunday Fund. A more undignified, unworthy and scurrilous attack upon a charitable organisation from a responsible member of a great public body it would be difficult to conceive. The Fund, apparently acting under the pressure of criticism at the Mansion House and elsewhere, made a grant to the Anti-vivisection Hospital. The concession was actually supported

by Sir Henry Burdett, who seconded the vote at the Mansion House, but, nevertheless, at the same time accused the hospital of "pretentious humbug," and expressed a hope that they would "mend their ways" and "fall in line with the best-administered hospitals of the country."

THE situation thus disclosed is an extraordinary one. The Sunday Fund having made a grant to a particular hospital, one of its Council members makes an insulting public attack on the institution, and follows it up by discussing the medical views of the hospital, and raking up a series of undignified recriminations in the philanthropic journal which he edits (*Hospital*, August 28th, 1909). Why, it may be asked, if heterodoxy be so great a rock of offence to Sir Henry Burdett, does he not oppose tooth and nail the grant to the Homœopathic Hospital? To us, as orthodox medical men, the cult of homœopathy is no whit more rational or defensible than that of anti-vivisection. The real issue appears to be that the Anti-vivisection Hospital is one of the small hospitals which the Hospital Sunday Fund and Sir Henry Burdett have long ago banned with bell, book and candle. One has only to glance at the smaller institutions of long and honourable history—tainted by no heterodoxy, and by no shadow except that of prolonged penury—to recognise the bitterness of the spirit that has decreed the extinction, if possible, of the smaller London hospitals.

THE root of the mischief lies in the An Autocratic constitution of the Fund. In a small administrative and absolutely irresponsible Council it is inevitable that the policy of the Fund should sooner or later drift into the hands of one or two members. There is no effectual control of the Fund by the public whose money it administers, a principle that is absolutely out of touch with modern views of the just economic relations of a great public trust. In the present instance, when a policy is insisted upon at the annual general meeting of the Sunday Fund—the only opportunity of united criticism of the management that is available—we find the decision of the meeting contemptuously handled by a prominent member of the Council, whose views are tacitly endorsed by his fellow-members. The whole situation is a burlesque upon the formally recognised machinery of modern public life. Until the constitution of the Metropolitan King Edward and Sunday Funds is altered, so that it becomes representative of all classes, including the hospitals themselves, the subscribers, the general public, and the medical profession, we are likely to be faced from time to time with a spectacle such as the present sordid squabble, from which the Fund certainly is not likely to emerge with any added lustre.

THE *Times* last week published two letters on this subject, both in their own way admirable and suggestive, the first from Sir Oliver Lodge, the second, in reply, from "M. D." Sir Oliver Lodge points to the fact that physical science is progressing too fast for the uneducated or semi-educated to follow, and the result is a tendency manifested in the Press, and even in the *Times*, to stigmatise the latest results as mere speculation. He explains that scientific theories are not speculations at all, but rather deductions from definite data. Speculation he defines as "guessing beyond any substantial founda-

tion," and when physicists speculate, "they unmistakably say so." It takes a generation or two for conclusions to sink into the popular mind, and then they are accepted, not so much by comprehension as by habit. Sir Oliver Lodge points out that the fact that the man-in-the-street lags hopelessly behind is a serious matter. The public have a monopoly of the sinews of war—money—and unless they can be made to understand the importance of pure science, and made willing to provide funds for its pursuit, the tendency of England to lag behind will increase, and one will fall back in the applications also. Sir Oliver clearly indicates the discouragement which present conditions impose upon workers in pure science, and pleads for more respect for the utterances of leaders in science. "M. D." shows how helpful it would be to the man-in-the-street if he could have scientific work set out for him like a railway plan, marking (1) lines completed; (2) lines under construction; (3) lines projected.

HE suggests that the confusion in the popular mind might thus be mitigated, especially if scientific men would all agree to get on with lines under construction, and not present so many that are merely projected as if they were completed. We have over and over again insisted that the only way to increase respect for the appreciation of science, lies in including a due proportion of science in our system of education from top to bottom. Everyone is a man-in-the-street in regard to some branch of science, but when properly educated he knows what to accept and what to reject. He accepts conclusions when satisfied that if he himself were to work out the research he would arrive at the same result; and he believes in conclusions when aware that the theories have been tested by scores of independent workers, an event that always speedily follows publication of the details of a research and its results. We must all accept authority in many matters of scientific fact; what the man-in-the-street needs is the power to distinguish between the real authority and the false pretender. The ignorant public need guidance. This they will never get sufficiently, so long as a large proportion of otherwise educated and cultivated men, who ought to be their leaders, are totally devoid of knowledge of science and of scientific methods. That this is at present the case in these islands is a fact constantly being exemplified in these pages, especially in relation with real medical science and its fraudulent counterfeits.

FOR the sake of the public it is to be regretted that the newspaper reports of the Congress and from the International Medical Congress at Budapest seem to be furnished by non-medical correspondents. It is only by collating reports, and reading between the lines, that an approximately correct interpretation can as a rule be arrived at, and by this method it is possible perhaps to describe what took place at the discussion on appendicitis which occupied the Congress on Thursday and Friday last. A large number of well-known surgeons, physicians, and obstetricians took part, and they divided themselves into three groups—those favouring operation in all cases, those for operation in selected cases, and those for no operation at all. According to the *Times*, which as usual provides by far the best reports, Dr. Lenhartz, of Hamburg, and Dr. Bourget, of Lausanne, were champions of the last named view. They asserted that by internal treatment, good nursing, and starvation, they had been able to show a lower mortality than the surgeons could show. The consensus of opinion

Science and  
the  
Man-in-the-  
Street.

The Medical Congress and from the International Medical Congress at Budapest seem to be

was, we are told, "against radical measures," and the practice of making an exploratory incision to determine whether an abscess had formed or not was condemned by most speakers. Dr. Sonnenburg, of Berlin, supported by many surgeons, agreed in favour of operation; but viewing the discussion in its entirety, it appears that the general opinion was that surgeons had operated too much in the past, and had now received a check.

#### A Medical Explorer.

THE interest felt by the civilised world in the great achievement of reaching the Pole will be increased in the case of the medical profession by the reflection that it is a medical man who has succeeded where so many failed. Dr. Frederick Albert Cook is a man of 45 years of age, a native of Brooklyn, and a graduate in medicine of New York. According to the *Jewish World*, he is descended from a well-known Frankfort family of the name of Koch. He began his exploring work in 1891, when he acted as surgeon to Peary's Arctic expedition. Again, in 1897, he undertook similar work as surgeon to the Belgian Antarctic expedition. More recently he did valuable work on his own account in the exploration of Alaska, and his description of his travels there was published not long ago. He showed himself an intrepid and determined adventurer, and, simple as his plan of reaching the Pole seems when the feat has been accomplished, yet it required considerable wisdom and courage to decide on such an original scheme and to carry it out in the face of all obstacles. The endurance which Dr. Cook was called upon to show must have been extreme, when, as he says, for days life was a torture. We join in the universal felicitations of our illustrious *confrère*.

#### The Health of Paris and London.

IN the course of the discussion of the Housing and Town Planning Bill in the House of Commons last week, an interesting comparison between the sanitary conditions of Paris and London was presented by Mr. John Burns. He clearly proved by statistics the superiority of London. The test of good sanitary administration, and of the condition of the mass of the people, is, of course, the death-rate; and the absence of consumption is equally significant. The death-rate of Paris ranges between 18, 19 and 20; the death-rate of London, which is twice the size of Paris, is 13.8, from 20 to 30 per cent. lower than that of Paris. The deaths from consumption in Paris for a year were 9,500, whilst only 9,176 died in London, in spite of its vastly greater population, from that disease. No less than 8,000 of the total deaths from consumption in Paris occurred in one area of contaminated houses. Paris is the most magnificent city in Europe from the æsthetic point of view. Every Parisian is willing to make any sacrifice to preserve and enhance the artistic qualities of his beloved city; but up to late years the inhabitants and their representatives, the municipal authorities, have been singularly lax regarding all those things to which the practical (and Philistine) Londoner has given most thought. In the housing of the people, imperfect as this may still be in many respects, in drainage, in water supply, in hospital isolation accommodation for infectious diseases, and in measures for dealing with consumption, London is far in advance of *la ville lumière*. Beneath its outward show of beauty, Paris conceals a vast number of foul plague spots such as are not to be discovered in anything like such a quantity behind the ignoble architecture of the meanest and most ill-looking of London streets.

## PERSONAL.

HIS MAJESTY THE KING has honoured Dr. Ott, of Marienbad, with an invitation to a private visit at Sandringham during the coming winter.

It is officially announced that the King has approved the appointment of Dr. Thomas H. Bryce, Lecturer in Anatomy in the University of Glasgow, to be Regius Professor of Anatomy in the University, in succession to Professor John Cleland, resigned. Dr. Bryce, who is a cousin of the British Ambassador to the United States, has been Lecturer on Anatomy at Queen Margaret College, Glasgow, since 1892.

A HANDSOME motor-car was last week presented by his fellow-citizens to Dr. R. Arthur Pritchard, Chairman of the Carnarvon County Council, and many times Mayor of Carnarvon.

MR. JOHN MARNOCH, M.A., M.B., C.M., Surgeon to, and Lecturer on Clinical Surgery at, the Aberdeen Royal Infirmary, has been appointed Regius Professor of Surgery in the University, in succession to Professor Alexander Ogston, who has resigned.

It has been calculated that about 4,000 members of the profession assembled last week at the International Medical Congress at Budapest. Of these, there were only fifteen women, four of whom were English and six American. All other nationalities combined, therefore, produced but five representatives of female practitioners.

THE funeral of Dr. John Milne Dalrymple, who died as the result of a cycle accident, as reported in our last issue, took place on August 30th at Edinburgh. Simultaneously a memorial service was held in the chapel attached to the Birmingham Infirmary, where Dr. Dalrymple had been until recently on the resident medical staff.

DR. H. RADCLIFFE CROCKER, Physician to the Skin Department of University College Hospital, whose death in Switzerland was announced in our last issue, has left estate valued at £17,778 gross, with net personality £15,328. He bequeathed to the Medical School of University College Hospital his drawings, sketches, diagrams, atlases, and books relating to diseases of the skin.

THE Council of the University of Birmingham has decided to confer a number of honorary degrees upon distinguished persons in connection with the recent opening of the new University by the King and Queen. Among the medical men thus honoured are Mr. Henry T. Butlin, F.R.C.S.; Sir Richard Douglas Powell, M.D.; and Dr. Wardle, F.R.S., the respective Presidents of Royal Colleges, and Mr. Charles S. Tomes, F.R.S., F.R.C.S., the President of the British Dental Association.

JACQUES ANTOINE REGNIER, a young doctor, æt. 21, died last week in Paris from blood poisoning caused by pricking his finger while conducting a post-mortem examination at the Necker Hospital. A few hours before he breathed his last he told those around his bed not to give way to grief. "I die like a soldier on the battlefield," he said. "When you take up the medical career you are aware of these dangers, and must be ever ready to face them."

LAST week it was announced from Copenhagen that an American medical man, Dr. F. A. Cook, had reached the North Pole, unaccompanied by any white man, on April 21st, 1908, while on a Polar expedition. Dr. Cook, who was born in Sullivan County, State of New York, in 1865, served as surgeon and ethnologist to the Peary Expedition in 1891-2, and has served in various capacities in other expeditions, and is President of the Explorers' Club of New York. According to the *Jewish World*, he is descended from a well-known Frankfort family of the name of Koch.

## EDUCATIONAL SUMMARY FOR 1909-10.

### INTRODUCTORY REMARKS.

#### CHOICE OF A CAREER.

THE choice of a career is the turning-point of the life of those whose career has not been pre-ordained by fortune or by sheer stress of circumstances. Of all the professions, medicine may claim to be the most learned, as it is the most catholic and liberal. There are few branches of scientific work that may not sooner or later be pressed into the service of scientific medicine, or, at the very least, may be the cause of fresh pathological phenomena that demand the ministrations of curative skill. Instances abound. Who could have prophesied that the researches of Crookes upon the passage of electric currents through high vacua would have given to surgeon and physician a generation later the marvellous wonder of the Röntgen rays? With that discovery came the curious form of traumatism known as X-ray or focus-tube dermatitis, which played such havoc amongst the pioneers in Röntgen-ray work, and the precise nature of which is not yet fully known. Truly this fragment of modern medical discovery, this romance of the laboratory, this outstanding symbol of intellectual progress and achievement, may well serve to kindle the fire of enthusiasm in the breast of the youth who is entering upon the formal study of medicine. And what has been true in the past is true to-day, and ever will be true—that no man knoweth the reward that may come to him in the shape of some great discovery that may reduce the vast sum of human misery, if only he labour patiently and observe and reason with absolute candour and exactitude. Yet it is given to many of the best workers in medicine to spend their whole lives in laborious toil and to have no crown of honour, of wealth, or of renown. There is no more pathetic thing to be seen in the whole tragedy of human life than the patient, unrequited toil of the man who has given up his whole life to the earnest search after truth.

It will be well for the student, and still more so for the intending student, to grasp the fact that medicine as a profession does not bring fortune to its followers. A mere living is sooner or later within the reach of most medical men, but, compared with other professions, the road to competency is getting harder and harder, competition is great, and the State does not hesitate to avail itself of medical services gratuitously, as in the recent legislation which made the notification of births by medical attendants compulsory (failing certain other specified persons), but which made no provision for the payment of a fee for the certificate. In the past the State fastened a similar unpaid and responsible duty upon the practitioner by requiring him to sign death certificates without fee. One day it is to be hoped that the medical profession will organise sufficiently to become a power in the State. The medical student will do well to give some consideration to matters of this kind that are outside his curriculum, for he will find himself one day brought face to face with a number of unpleasant experiences in actual practice.

Of all the influences that direct prosperity from the door of the medical man, there are none at all comparable with those of quack practice and quack medicines. The law that insists on a full curriculum for the medical student, and upon his passing carefully

regulated standards of examination before he receives a qualification to practice, stops at that point. It is permitted to Dick, Tom, and Harry to set up at their own sweet will as skin, eye, and nerve specialists, as cancer curers, bone-setters, or any other branch of pseudo-medical practice they may choose, without having a single scrap of medical knowledge. Of late the General Medical Council has been making inquiries, and has induced the Government to take the matter up to some extent. Except for that action, no medical body had ever attempted to defend the medical profession, not to mention the public, against the terrible abuses that are inseparable from the wiles of the charlatan and the fraudulent lies of the quack medicine vendor. In no other path of modern life is fraud permitted to stalk brazenly through the streets, but in the case of these parasites of society, usage appears to have conferred a species of immunity.

But though there are rocks ahead in the career of medicine, the same thing is true of all walks of life. The earnest student who is content to look forward to a life spent in the service of his fellows, and is content with rewards that are those of the virtuous rather than of the acquisitive mind, may turn to his work with confidence for the future. Wherever his lot may be cast, it will be possible for him to make scientific observations that may prove of incalculable benefit to mankind. Medical men are never weary of the story of Jenner and vaccination. Nor, in truth, in the whole history of medicine can there be a more striking instance of brilliant inductive reasoning than that which established the practice of vaccination. Later discoveries have placed the work of Jenner on a more and more secure basis of ascertained fact. So far as absolute demonstration of the truth of his views as to the preventive value of vaccine are concerned, sufficient evidence is forthcoming to satisfy any but the stubborn incredulity of an anti-vaccinationist. The sole factors wanting to a scientific solution of the whole question are the identification of a specific small-pox organism, and a fuller understanding of the nature of immunity. Meanwhile, the scourge of small-pox has been practically driven out of the United Kingdom by the empirical observations of a country surgeon. That fact is encouraging to those who are content to carry on their profession with devout sincerity and belief in the nobility of their work. At the same time, it must not be forgotten that there is a material side to the question, and that medical men in common prudence should defend their interests with regard to fees, and to the many encroachments upon their legitimate field of practice, which, of late years, have reduced incomes in many cases well-nigh to vanishing point. What would have been the position of Jenner if poverty had driven him to give up his practice and take to another calling? Yet that is precisely what is taking place with the present-day Jenners, and with this remark we conclude our introductory section. The public is deluded into wasting its money upon quacks and charlatans, who work incalculable evil in return. The remedy for this state of affairs rests with the medical profession, who cannot hope for fair treatment at the hands of the outside world until they set their own house in order by the reform of the medical corporations, and of the General Medical Council.

## CHOICE OF A SCHOOL.

Many influences combine to make for the choice of a school. Tradition, family influence, proximity, means, and acquaintance with other students or members of the staff all come into play, and there are few who are not affected by them. The would-be student, however, who has the whole collegiate domain open to him and his selection unhampered by any consideration than that of merit, has the choice of nearly twenty centres at which to follow his bent. As practically all these establishments and schools are badly off for money, and not too rich in students, he may calculate on finding himself welcomed wherever he finally decides to go, which is indubitably an advantage at the outset of a career. There is, as a rule, a certain tendency for a man to look to his immediate vicinity for the maturing of his genius, and in these days, when Universities are cropping up with bewildering prolixity, most students will probably find one within fifty or sixty miles of their homes. As the medical curriculum is laid down carefully by the General Medical Council, there is not much variation in that of the individual schools, and a good all-round education can be relied on in practically every one. On the other hand, some have teachers of established ability and reputation, whilst others are seeking to obtain that enviable notoriety, and while some men may be attracted by the spirit of adventure to cast in their lot with the new and struggling, others will prefer the security of well-trodden paths. The object of this number of *THE MEDICAL PRESS AND CIRCULAR* is to present impartially the claims and attractions of all schools, and if parents and their wards study its pages carefully they will, we feel sure, be convinced that there are none that have not their own special charms. The outlay on actual necessary educational expenses does not differ very materially in different places, the higher cost of certain centres being chiefly due to the greater cost of living. It is obvious that in London, for instance, where rents are high, the cost of lodgings must be considerably more than in many smaller and less favourite towns, while, on the contrary, a student living in his parents' home in London will not be so much expense to them if he goes to a London Hospital as if he takes up his abode at a northern University. But, other things being equal, it is important for the average student to choose that school at which he is most likely in after years to obtain a resident post.

## CHOICE OF A QUALIFICATION.

One day, in the not very distant future, we hope, the choice of what qualification to study for will not present so great a difficulty as it does to-day. Owing to the haphazard way in which British institutions and customs grow up, there have come into being a number of rival interests, both pecuniary and scholastic, which it is very difficult to break down, with the result that students are offered all sorts of qualifying diplomas, conferring on them the right to append almost every conceivable alphabetical combination to their names. It may be laid down in general terms that the shortest and least picturesque of these designations will generally be found the most serviceable, both from the expenditure of time that it will save in signing certificates, and in the greatest ease by which it will be understood of the people. Happily, or unhappily, a qualification even of the highest order has, as a rule, but small relation to success in practice, and many practitioners of light and leading will be found to have laid the foundations of their success on a more solid basis than that of academical triumph.

## COURSE OF STUDY.

Although there are certain individual variations, the course of study pursued at all the medical schools is pretty much the same. One or two of the Universities are a little exacting in the number of special subjects they pile on to the crouching backs of their alumni, but in course of time it is generally found that the other centres of instruction follow their lead. Still, it is well to remember that from the moment the student pays his fee to the dean, the disposition of each moment of his time for the next five years is laid down with procrustean exactness, and that any diversion in the shape of amusement, illness, or failure in examination connotes a corresponding addition to the length of his pupilage.

## THE ULTIMATE FUTURE.

Once qualified, a medical man can therefore consult his predilections in some degree as to where he will practise his profession, though he will probably find the choice somewhat narrowed by the pecuniary resources at his disposal and the meagre opportunities offered for enterprise in the vicinity of popular, established practitioners. If he be averse from the struggle for existence in the troubled waters of private practice, he may turn to the comparative haven of competency afforded by the services. The Army, Navy, Indian, Colonial, and West African appointments may tempt him abroad, or the Poor-law infirmaries, lunatic asylums, public health officerships, or fever hospitals, may prevail on him to remain at home. In all the official Government services there is a career with graduated promotion and certain pension, whilst in the local services at home promotion is very uncertain, the pay, except in a few instances, very poor, and a pension either not provided or calculated on a studiously thrifty basis. One of the special advantages of medicine is that its votaries are nearly always sufficiently in request to be able to pick up a living as long as health lasts, and when old age comes on the practitioner will find that a parental Government is willing to pay him 5s. a week to the end of his days, provided he has not availed himself of Poor-law relief in the meantime.

## SUMMARY.

There are two types of men which find in medicine the most satisfying career. One is he who has a strong affinity for nature and natural phenomena. To such the profession of healing offers numberless opportunities for applying their peculiar powers, and gives much entertainment by the elusiveness of its secrets. The other class of man which finds satisfaction in the practice of medicine is he who regards the welfare of others before his own comfort and convenience. These rare beings, less rare probably in the medical profession than in any other, make devoted practitioners among the poor, and do not account their labour wasted if their patient gets well but cannot afford through stress of illness to pay the bill. The man who does not get on well at medicine is he who wishes to account for all his services on a cash basis, and to make his practice a purely business concern. As a matter of fact, it is not possible to translate personal services into an exact money equivalent, and much unpleasantness pursues the path of him who tries to do so. The best that many men hope for is that a reasonable number of honest and grateful people will be found so far to appreciate his services that he is relieved of financial strain for the next half-year.

Medicine, then, is the means to an end, and that end is the amelioration of man's lot on earth and not the aggregation of wealth. As the first it is a brilliant success; as the latter, it is a sorry business.

## THE ENGLISH UNIVERSITIES.

The English Universities are ten in number, *viz.*, Oxford, Cambridge, London, Manchester, Durham, Liverpool, Leeds, Sheffield, Birmingham and Bristol, beside the University of Wales. The choice of a University is usually determined by social, geographical, and financial considerations. Students whose parents are able and willing to incur the necessary expense will do well to select one of the ancient Universities, since their degrees confer upon their holders a status not accorded by the public to the degrees of more modern institutions. To those less favoured by fortune, but blessed with energy and a fair share of intelligence, the London University offers ample scope, and its degrees are recognised as the outward and visible sign of high professional attainments. A capable and industrious student, however, may equally well lay the foundations of success in one of the newer provincial Universities.

## OXFORD.

There are two degrees in medicine, B.M. and D.M., and two degrees in surgery, B.Ch. and M.Ch. The B.M. and B.Ch. degrees are granted to those members of the University who have passed the second (B.M.) examination. Graduates in Arts, B.A., are alone eligible for these degrees. In order to obtain the degrees of B.M. and B.Ch., the following examinations must be passed:—1. Preliminary. Subjects:—Mechanics and physics, chemistry, zoology and botany. 2. Professional. (a) First examination (held twice a year): Subjects:—Organic chemistry, unless the candidate has obtained a first or second class in chemistry in the Natural Science School; Human physiology, unless he has obtained a first or second class in animal physiology in the Natural Science School; Human anatomy. (b) Second examination: Subjects:—Medicine, surgery, midwifery, pathology, materia medica and pharmacology, forensic medicine with hygiene. The approximate dates of the examinations are as follow:—Preliminaries:—December, March and June; Professional (First and Second B.M.), June and December.

The degree of D.M. is granted to Bachelors of Medicine of the University who have entered their thirty-ninth term on presenting a dissertation approved by the appointed professors and examiners.

The degree of M.Ch. is granted to Bachelors of Surgery of the University who have entered their twenty-seventh term, who are members of the surgical staff of a recognised hospital, or have acted as dresser or house surgeon in such a hospital for six months, and who have passed an examination in surgery, surgical anatomy, and surgical operations. This examination is held annually, in June.

**Diploma in Public Health.**—The examination for the Diploma is held about the end of November in each year, and is open to any registered medical practitioner, whether he be a graduate of the University of Oxford or not. It is conducted according to the statutes and regulations of the University, and these have been framed so as to be consonant with the Resolutions and rules adopted by the General Medical Council for Diplomas in Public Health.

The examination consists of two parts. In the first of these candidates are required to exhibit a knowledge of chemistry and physics in the relations of these sciences to Public Health. In the second part of the Examination the candidate is examined in the subjects of general hygiene and of pathology in its bearings on Public Health. In all the subjects the Examination is partly practical. Candidates may offer themselves for the two parts of the examination on the same occasion or on different occasions; but their admission to the second part is contingent on their having already satisfied the examiners in the first part.

In July 1910 there will be an examination for the newly-established diploma in Ophthalmology.

There are many valuable prizes and scholarships, details of which may be obtained from the University Calendar.

Candidates who desire to prepare for the examina-

tion within the University will be afforded facilities for doing so in the laboratories of the scientific departments concerned with the subjects of examination; and arrangements can also be made for candidates to acquire a practical knowledge of the duties of Public Health administration under the supervision of the Medical Officer of Health for the City of Oxford. Information on these points may be obtained by application to the Regius Professor of Medicine, University Museum, Oxford.

## UNIVERSITY OF CAMBRIDGE.

At the University of Cambridge five years of medical study are required for the M.B. and B.C. degrees. The candidate must have resided nine terms (three years) in the University, and have passed the "previous" examination in classics and mathematics. There are three examinations: The first in (1) chemistry, physics, and (2) biology; the second in human anatomy and physiology; and the third in (1) pharmacology and general pathology, (2) in surgery, midwifery, and medicine. The first examination is divided into three parts, and the third examination into two parts, which can be taken separately. Subsequently to the third examination an Act has to be kept which consists in reading an original thesis, followed by an oral examination on the subject of the thesis. As the subjects for the examination for the degree in surgery are included in the third examination for the M.B. degree, candidates are admitted to the degree of Bachelor of Surgery on passing the third examination for Bachelor of Medicine.

The M.D. degree may be taken three years after the M.B. An Act has to be kept, including the presentation of an original thesis, with oral examinations and an essay to be written extempore. There is also the degree of Master of Surgery, for which the candidate, having already passed for B.C., or being M.A., has otherwise qualified in surgery, has to pursue extra study in surgery, and has a special examination or submits original contributions of merit to the science or art of surgery. The yearly expenditure of a student who keeps his term by a residence in a college is from £150 to £200 a year. This, however, may include all payments to the University and the College—all fees as well as clothes, pocket money, travelling expenses, &c. Non-collegiate students have only to pay the University fees, which are not large. They lodge and board as they like; their expenses, therefore, are entirely in their own hands.

The University grants a diploma in public health without the necessity of residence, the examination being in so much of State Medicine as is comprised in the functions of officers of health, and subject to the latest requirements of the General Medical Council. These examinations are held in Cambridge the first week in April and October. Candidates, whose names must be on the "Medical Register" of the United Kingdom, and need not be members of the University, should send in their applications to the Secretary of the State Medicine Syndicate a fortnight in advance. Every candidate who has passed both parts of the examination to the satisfaction of the examiners will receive a University Diploma testifying to his competent knowledge of the subjects comprised in the duties of a medical officer of health.

There is also a special examination in Tropical Medicine and Hygiene, held annually twice, in January and in August. It is open to qualified practitioners under certain conditions as to previous study and experience. Successful candidates receive a University Diploma.

At the October Examinations, Part I. will begin on October 7th, Part II. on October 12th.

An abstract of all Regulations may be obtained upon sending a stamped directed envelope to the Assistant Registry, Cambridge. Full information is contained in the University Calendar.

## UNIVERSITY OF LONDON.

The Medical Faculty grants the degrees of Bachelor of Medicine and Surgery, Doctor of Medicine and Master in Surgery. Under the new regulations the

students are divided into "Internal" and "External." Internal students are students who have matriculated at the University, and who are pursuing a course of study approved by the University, either (a) under the direct control of the University or a committee appointed thereby, or in one or more of the schools of the University; or (b) under one or more of the appointed or recognised teachers of the University. An external student is one who has adopted an alternative course of study. The regulations differ somewhat in their application to the two groups of students. We propose to deal with them only as they affect *internal* students, since the special information required by the others had best be obtained direct from the Registrar. Under no circumstances will a student be admitted to the final examination for a degree until at least five years have elapsed since matriculation or other examination entitling to registration as a medical student.\*

*The Matriculation Examination* takes place thrice yearly—in January, June (or July), and September. Application for admission to it must be made on a special form about six weeks beforehand, and the candidate must have completed his 16th year at the date of the examination. Candidates must show a competent knowledge of five subjects, among which must be English and elementary mathematics.

*The First Examination for Medical Degrees* takes place twice in each year, in December and July, and consists of papers on inorganic chemistry, biology, and physics, and there will be a practical examination in each subject. Examiners will also be at liberty to test candidates *viva voce*. A student may present himself for examination in each of the three subjects, separately or in all at the same time. Part I. of this examination includes papers in inorganic chemistry, physics, and biology, with practical examinations; second examination for medical degrees, Part I., is an examination in organic chemistry. Six months must elapse after passing the first examination for medical degrees.

*The Second Examination for Medical Degrees, Part II.*, takes place twice a year, March and July. Candidates must have passed the First Examination for Medical Degrees at least two years previously. The subjects of examination are Anatomy, Physiology and Histology, and Pharmacology, including *Materia Medica*. Candidates who have failed in one subject only at this examination may offer themselves for re-examination in that subject, if permitted to do so by the examiners. Three scholarships, one of the value of £40 in Anatomy, another of the same amount in Physiology, and one of £30 in Pharmacology, may be awarded by the examiners to any candidate who has passed the whole of the examination at one time.

*Provincial Examinations for Matriculation.*—These examinations are appointed by the Senate from time to time upon the application of any city, institution, or college desiring to be named as a local centre for one or more examinations in London under the supervision of sub-examiners also appointed by the Senate. Candidates wishing to be examined at any centre must give notice upon their forms of entry to the Principal of the University. Besides the University fee a fee usually varying from £1 to £3 is charged by the local authorities and must be paid at the local centre before the commencement of the examination.

*The Third Examination for Medical Degrees or M.B., B.S.*, takes place twice a year, in October and May. No candidate is admitted to this examination unless he has completed the course of study prescribed in the schedule or in less than two academic years from the

date of passing the Second Examination for Medical Degrees, Part II., in anatomy and physiology.

The subjects of the examination are Medicine (including Therapeutics and Mental Diseases), Pathology, Forensic Medicine and Hygiene, Surgery, and Midwifery and Diseases of Women. The subjects may be divided into two groups. Either of which may be taken first at the option of the candidate, or the groups may be taken together.

*Doctor of Medicine.*—The examination for this degree is held twice a year, in December and July. Candidates must have passed the examination for the M.B., B.S., and may present themselves for examination in one of the following branches: (1) Medicine, (2) Pathology, (3) Mental Diseases, (4) Midwifery and Diseases of Women, (5) State Medicine, (6) Tropical Medicine; and if they wish, may pass also in another branch at a subsequent examination. Candidates for Branches 1 to 4 who have taken honours at the M.B., B.S. examination in the subject in which they present themselves for the M.D. degree, or who, subsequently to taking the M.B., B.S., have conducted a piece of original work approved for the purpose by the University, or have had special experience approved by the University, may present themselves for the M.D. examination one year after taking their Bachelor's degree. Candidates in Branch 5 (State Medicine) must show that they have taken the degrees M.B., B.S., not less than two years previously, and that subsequently to taking those degrees they have had (1) six months' practical instruction in an approved laboratory; (2) six months' practical instruction from a medical officer of health, of which three must not coincide with the laboratory work, and three months' practice at a hospital for infectious diseases. Candidates in Branch 6 (State Medicine) must have either passed that subject with honour in the M.B.; or have done approved original work; or have approved special experience. The interval between passing the M.B., B.S. and proceeding to the M.D. State Medicine may be reduced to one year, subject to conditions corresponding to those affecting Branches 1, 2, 3, and 4.

*Master of Surgery.*—The examination for this degree takes place twice in each year, commencing on the same dates as the foregoing, and the general regulations with regard to the M.D. practically apply to it, surgery being substituted for medicine.

*Fees.*—For Matriculation, £2 for each entry. Preliminary Scientific Examination.—Part I: £5 for each entry to the whole examination, and £2 for each subject when less than the whole examination is taken at one time. Part II.: No fee for first entry, £2 for each subsequent one. Intermediate Examination.—£10 for each entry to the whole examination, and £5 for re-examination in one subject. M.B., B.S. Examination.—£10 for each entry to the whole examination, and £5 for examination or re-examination in either group. M.D. and M.S. Examinations.—£20 for each entry.

This University has established centres for preliminary and intermediate studies at University and King's Colleges, and students who purpose taking the London degree should make themselves acquainted with the details attached to external and internal students. Information on these points may be had of the Academic Registrar, University of London, South Kensington.

*N.B.*—The new regulations came in force on July 1st last. Students who commenced their course before that time are entitled to certain exemptions and should apply in any case to the Registrar for confirmation.

#### UNIVERSITY OF DURHAM.

Two diplomas and six degrees in Medicine and Hygiene are conferred, *viz.*, the degrees of Bachelor of Medicine, Bachelor of Surgery, Master of Surgery, Doctor in Medicine, Bachelor of Hygiene, and Doctor of Hygiene, and Diplomas in Public Health and Dental Surgery. These degrees are open to both men and women.

For the degree of Bachelor of Medicine (M.B.), there are four professional examinations. The subjects are:

\* May obtain registration as Internal or External students on presentation of documentary evidence as to their condition and a payment of £2; Graduates of such British, Colonial, and foreign Universities as are approved by the Senate for that purpose, and those who have passed all the examinations required for a degree in those Universities, also women who have obtained Tripos certificates granted by the University of Cambridge, and women who have obtained certificates showing that, under the conditions prescribed by the Delegacy for Local Examinations at Oxford, they have passed the Second Public Examination of that University or have obtained honours in the Oxford University Examination for Women in Modern Languages, and students who hold the Scotch School Leaving Certificate, having passed on one and the same occasion, in the Higher or Honours Grade in all the subjects required by the regulations for the Matriculation Examination.

Elementary anatomy, biology, chemistry, and physics. For the second: Anatomy, physiology, materia medica, therapeutics, and pharmacology. For the third: Pathology, medical jurisprudence, public health, and elementary bacteriology; and for the fourth: Medicine, clinical medicine and psychological medicine, surgery and clinical surgery, midwifery, and diseases of women and children.

It is required that one of the five years of professional education shall be spent in attendance at the University College of Medicine and the Royal Victoria Infirmary, Newcastle-upon-Tyne. First and second year students (dating from registration) are not required to comply with the regulation regarding attendance on hospital practice. Candidates who have passed the First and Second Examinations of the University will be exempt from the First and Second Examinations of the Conjoint Board.

For the degree of Bachelor of Surgery (B.S.) every candidate must have passed the examination for the degree of Bachelor of Medicine of the University of Durham, and must have attended one course of lectures on operative surgery, and one course on regional anatomy. Candidates will be required to perform operations on the dead body, and to give proof of practical knowledge of the use of surgical instruments and appliances.

For the degree of Master of Surgery (M.S.) candidates must not be less than twenty-four years of age, and must satisfy the University as to their knowledge of Greek or German. In case they shall not have passed in either of these subjects at the Matriculation Examination for the M.B. degree, they must present themselves at Durham for examination in it at one of the ordinary examinations held for this purpose before they can proceed to the higher degree of M.S. They must also have obtained the degree of Bachelor of Surgery of the University of Durham, and must have been engaged for at least two years subsequently to the date of acquirement of the degree of Bachelor of Surgery in attendance on the practice of a recognised hospital, or in the naval or military service, or in medical or surgical practice.

For the degree of Doctor of Medicine (M.D.) candidates must be of not less than twenty-four years of age, and must satisfy the University as to their knowledge of Greek or German. In case they shall not have passed in either of these subjects at the Matriculation Examination for the M.B. degree, they must present themselves at Durham for examination in it at one of the ordinary examinations held for this purpose before they proceed to the higher degree of M.D. They must also have obtained the degree of Bachelor of Medicine of the University of Durham, and must have been engaged for at least two years, subsequently to the date of acquirement of the degree of Bachelor of Medicine, in attendance on the practice of a recognised hospital or in the naval or military services, or in medical or surgical practice.

Each candidate must present an essay which has been prepared entirely by himself (and typewritten), based on original research or observation, on some medical subject selected by himself, and approved by the Professor of Medicine, and must pass an examination thereon, and must be prepared to answer questions on the other subjects of his curriculum, so far as they are related to the subjects of the essay.

Candidates for any of the above degrees must give at least twenty-eight days' notice to the Secretary of the College of Medicine, Newcastle-on-Tyne. In the case of the M.D. (Essay) Examination, candidates must send in their essays six weeks before the date of the examination.

A new wing has been added to the College of Medicine to accommodate the departments of physiology and bacteriology. It also contains students' union rooms and gymnasium.

The New Royal Victoria Infirmary, containing 400 beds, was opened by H.M. the King, in July, 1906. In the new infirmary adequate accommodation is provided for the study of the various special subjects, in addition to the ordinary clinical work.

Practical midwifery can be studied at the Newcastle Maternity Hospital. Opportunities for practical study are also afforded by the Dispensary, City Infectious Diseases Hospital, Eye Infirmary, and at the Northumberland County Lunatic Asylum.

There are various appointments open to students, whilst the scholarships available are numerous and of considerable value.

**Fees.**—(a) A composition ticket for lectures at the college may be obtained—1. By payment of 72 guineas on entrance. 2. By payment of 46 guineas at the commencement of the first sessional year and 36 guineas at the commencement of the second sessional year. 3. By three annual instalments of 36, 31, and 20 guineas, respectively, at the commencement of the sessional year. A Composition Ticket for the course of lectures and practical work of the first two years of the curriculum may be obtained by the payment of 40 guineas on entrance. (b) Single courses of lectures, five guineas. (c) Fees for attendance on hospital practice: For three months' medical and hospital practice, five guineas; for six months, eight guineas; one year, twelve guineas; composition fee in one payment, twenty-five guineas; or by three instalments at the commencement of the sessional year, viz., first year, 12 guineas; second year, ten guineas; third year, six guineas; or by two instalments, viz., first year, fourteen guineas; second year, twelve guineas. In addition, two guineas yearly up to three years must be paid to the Committee of the Royal Infirmary. (d) Composition fee for lectures, &c., at the College for the Diploma in Dental Surgery, 34 guineas. Composition fee for dental practical work at Newcastle Dental Hospital, 35 guineas.

A Diploma in Dental Surgery has been instituted. Before admission to the Final Examination, each candidate must furnish evidence, (1) of having attained the age of 21 years, (2) of having undergone a three-years' pupillage in mechanical dentistry with a registered dentist, and (3) of having been engaged in professional study for at least four years subsequent to registration as a dental student. He must also sign such declaration as the University may determine, binding himself not to advertise for professional purposes. Examinations are held concurrently with the medical examinations, and the fees payable by candidates amount to £15.

Further particulars will be given on application to Prof. Howden, Secretary, University of Durham College of Medicine, Newcastle-on-Tyne.

**N.B.**—The new regulations have recently come into force. Students who commenced their course under the old regulations are entitled to various exemptions. In all cases such students had better apply for confirmation to the Registrar.

#### MANCHESTER UNIVERSITY.

Candidates for degrees in medicine and surgery must attend classes in the University during at least two years.

The Degrees in the Faculty of Medicine are Bachelor of Medicine (M.B.), Bachelor of Surgery (Ch.B.), Doctor of Medicine (M.D.), and Master of Surgery (Ch.M.). All candidates for Degrees in medicine and surgery are required to pass the Matriculation Examination, or to have passed such other examination as may from time to time be recognised for this purpose by the University.

The subjects of the Matriculation Examination (Faculty of Medicine) are—1, English language or literature; 2, English history; 3, Mathematics; 4, Latin; 5, two of the following; one of which must be a language:—(a) Greek; (b) French; (c) German; (d) some other modern language, approved by the Joint Matriculation Board; (e) elementary mechanics; (f) chemistry; (g) geography (physical, political, and commercial); (h) Natural History (plants and animals). Notice of intention to present either Italian or Spanish must be given to the Secretary, Joint Matriculation Board, Manchester, before March 1st in each year.

Before admission to the Degrees of Bachelor of Medicine and Surgery candidates are required to send in the

usual certificates of age and study as at the other Universities. All candidates for these Degrees must pass four examinations, and must have attended courses of both lectures and laboratory work.

The final examination cannot be taken before the fifth year of medical study in accordance with the University regulations. The subjects of examination are as follows: 1, Medicine, systematic and clinical, including mental diseases and diseases of children; 2, Surgery, systematic, clinical, and practical; 3, Obstetrics and diseases of women; 4, Forensic medicine and toxicology.

The certificates required from candidates at the Third and Final examinations are practically the same as for the Final examination at the London University, and only those who have previously passed the Second Examination are admitted to it. The regulations relating to the M.D. and Ch.M. Degrees can be obtained on application to the Registrar.

*Fees.*—Matriculation examination, £2. First Examination, £5; for any subsequent examination, £2. The fees for the Second Examination, for the Third and Final Examinations, and for the examination for the degree of Ch.M., are the same as for the First Examination. A fee of £10 is payable on the conferring of the degree of M.D., a fee of £5 on the conferring of the degree of Ch.M.

The Matriculation Examination is held in July and in September. The first M.B. and Ch.B. is held in June; also about the end of September. The second examination is held in December, and in March, the third examination in March, July and December; the Final in July and March; the examination for Ch.M. in July only.

The medical school buildings, which include large laboratories, dissecting-rooms, library and reading-rooms, are on the most modern principles, and students wishing to engage in anatomical, physiological, or pathological research will find excellent opportunity for study in the complete and well-furnished laboratories. Hospital practice is taken out at the (a) Royal Infirmary, which contains 592 beds. The Cheadle Lunatic Asylum, St. Mary's Hospitals, the Southern Hospital, and other special hospitals also afford teaching facilities of great importance.

The appointments open to students are numerous and of considerable monetary value, and there are probably more here than are available at any other medical centre. The principal are:—Nine Entrance scholarships, the Leech fellowship of £100; Entrance scholarships in medicine, £100 (towards University and Infirmary fees); Manchester Grammar School scholarships, two or three of not less than £15 or more than £30 per annum for three years; Dreschfeld Memorial Scholarship £30, awarded annually; Turner scholarship of £20 to students who have completed a course of medical study in the University; Platt physiological scholarships, two of the value of £50 each; Platt zoological and botanical scholarship, £50; Professor Tom Jones' memorial surgical scholarship of £100, awarded triennially; two Dauntsey medical entrance scholarships, value £35; John Henry Agnew scholarship in diseases of children, value £30, awarded annually; Graduate scholarship in medicine, £25 to £50, awarded annually; and many others.

*Fees.*—For courses of instruction for the degrees of M.B., and Ch.B., of the University:—For the first M.B. examination the total cost amounts to about 28 guineas payable on entry. A composition fee of 70 guineas, payable in three instalments of 30, 20, and 20 guineas, at the commencement of the second, third, and fourth years of studentship respectively, admits to the courses of instruction required for the degrees of M.B. and Ch.B.

*Dental Fees.*—The composition fee for candidates for the University degree of Bachelor of Dental Surgery is 60 guineas, and for candidates for the University diploma in Dentistry is 55 guineas, payable in two equal instalments at the beginning of the first and third years of studentship.

## UNIVERSITY OF BIRMINGHAM.

The University of Birmingham grants Degrees of M.B., Ch.B., M.D., Ch.M., and also a B.Sc. in the subject of Public Health. As a rule, in order to obtain any of these Degrees it is necessary that a student shall have passed at least the first four years of his curriculum in attendance upon the classes of the University, but the Senate has power of recognising attendance at another University as part of the attendance qualifying for these degrees.

*Degrees of Bachelor of Medicine and Bachelor of Surgery.*—The student must have passed either the Matriculation Examination of the University or one of the following examinations, which will be accepted in lieu thereof for the present:—(a) The previous examination of the University of Cambridge; (b) Responsions of the University of Oxford; (c) The matriculation examination of any other University in the United Kingdom; (d) The leaving certificate (higher) of the Oxford and Cambridge Boards; (e) The Oxford or Cambridge senior local examination.

Matriculation Examinations are held in July and September each year.

*Degrees of Doctor of Medicine and Master of Surgery.*—At the end of one year from the date of having passed the Final M.B., Ch.B. Examination, the candidate will be eligible to present himself for the higher Degrees of either Doctor of Medicine or Master of Surgery or both, the regulations for which may be had upon application to the Dean. The University also grants a Degree and a Diploma in Public Health, and provides adequate instructions for the same.

*Dental Department.*—The University grants the Degrees of Bachelor and Master of Dental Surgery (B.D.S. and M.D.S.), and a Diploma in Dental Surgery (L.D.S.). The whole of the instruction for which may be taken out in the University, with which is associated the Birmingham Dental Hospital.

*THE GENERAL AND QUEEN'S HOSPITALS.*—The practices of these hospitals are amalgamated for the purpose of clinical instruction under the direction of the Birmingham Clinical Board, by whom all schedules will be signed and all examinations conducted. The hospitals have a total of upwards of 500 beds, 8,000 in-patients and 80,000 out-patients are treated annually, and many valuable posts are open to students at both.

Further information can be obtained from Professor Gilbert Barling, Dean of the Medical Faculty.

## THE UNIVERSITY OF LIVERPOOL.

The Degrees in the Faculty of Medicine are Bachelor of Medicine and Bachelor of Surgery (M.B. and Ch.B.), Doctor of Medicine (M.D.), and Master of Surgery (Ch.M.). The course of study for the Degrees of Bachelor of Medicine and Bachelor of Surgery is of five years' duration, and of this period two years must be spent at the University, the remaining three years can be taken in any medical school approved by the University.

For the Degree of M.D., a thesis is required which may be presented not earlier than one year after graduation, as M.B., Ch.B.

The degree of Ch.M. is given after a period of at least one year of further study after graduation as M.B., Ch.B., on the results of an examination.

*Diplomas.*—Diplomas have been instituted in Public Health (D.P.H.), Tropical Medicine (D.T.M.), and Veterinary Hygiene (D.V.H.). Special diplomas are also granted in Anatomy, Bacteriology, Bio-chemistry, and Parasitology after a course of study of three terms in the subject chosen and allied subjects.

Students may enter for the degrees of the University of Liverpool, or may study for the degrees, diplomas and qualifications of the other licensing bodies.

*Hospitals.*—The Clinical School of the University now consists of four general hospitals—the Royal Infirmary, the David Lewis Northern Hospital, the Royal Southern Hospital, and the Stanley Hospital; and of five special hospitals—the Eye and Ear Infirmary, the Hospital for Women, the Infirmary for Children, St. Paul's Eye and Ear Hospital, and St. George's Hospital for Skin Diseases. These hospitals

contain in all a total of 1,127 beds. The organisation of these hospitals to form one teaching institution provides the medical student and the medical practitioner with an unrivalled field for clinical education and study, and all are within easy access from the University. The period of hospital practice extends over the last three years of medical study. There are a large number of appointments to House Physicianships and Surgeonships both at the general and special hospitals, which are open to qualified students of the School. These appointments (20) in most cases carry salaries varying from £60 to £100 per annum.

**Fellowships and Scholarships.**—Fellowships, Scholarships, and Prizes of over £800 are awarded annually. A Holt Fellowship in Pathology and Surgery, of the value of £100 for one year, is awarded annually by the Medical Faculty to a senior student possessing a medical qualification. A Holt Fellowship in Physiology, awarded under similar conditions, also of the value of £100 for one year. A Robert Gee Fellowship in Anatomy, awarded under similar conditions, of the value of £100 for one year. An Alexander Fellowship for Research in Pathology of the annual value of £100, renewable. A Johnston Colonial Fellowship in Pathology and Bacteriology (£100 a year, renewable). A John W. Garrett International Fellowship in Physiology and Pathology (£100 a year, renewable). An Ethel Boyce Fellowship in Gynaecological Pathology (£100 a year, renewable). A Thelwall Thomas Fellowship (£100 a year, renewable) in Surgical Pathology. Two Lyon Jones scholarships, of the value of £21 each for two years, are awarded annually—a Junior Scholarship, open at the end of the first year of study to Liverpool University students in the subjects of the first M.B. Examinations, and a Senior Scholarship, open to all students in the school at the end of the second or third year of study, in the subjects of Anatomy, Physiology, and Therapeutics. A University Scholarship of £25 awarded on the results of the second examination for the degree. The Derby Exhibition of £15 for one year is awarded in Clinical Medicine and Surgery in alternate years. Students may compete in their fourth and fifth years. A Clinical School Exhibition of £15 awarded under similar conditions. The Torr Gold Medal in Anatomy, the George Holt Medal in Physiology, the Kanthack Medal in Pathology, and the Robert Gee Book Prize, of the value of £5, for Children's Diseases.

**Entrance Scholarships.**—Two Robert Gee Entrance Scholarships, of the annual value each of £25 for two years, are offered annually for competition. The holder is required to take out the First M.B. Course for the University Degree in Medicine.

The University also grants a Diploma in Dental Surgery (L.D.S.) and Degrees in Dental Surgery (B.D.S. and M.D.S.) The courses of systematic instruction are given in the University buildings, five minutes walk from the Dental Hospital.

Communications should be addressed to the Dean, Mr. K. W. Monsarrat, F.R.C.S., the University, Liverpool.

**LIVERPOOL SCHOOL OF TROPICAL MEDICINE, AND DIPLOMA OF TROPICAL MEDICINE, UNIVERSITY OF LIVERPOOL.**—The school is affiliated with the University of Liverpool and the Royal Southern Hospital of Liverpool. The instruction given occupies six hours a day for five days a week during the term, which at present is of ten weeks' duration. At the beginning of next year, however, there will be but two courses instead of three, and each extending to thirteen weeks. Each Course consists of (1) of a systematic series of lectures on tropical medicine and sanitation delivered by the Professor of Tropical Medicine at the University; (2) of additional lectures on special African diseases and special Indian diseases delivered at the University; (3) of systematic lectures and demonstrations on tropical pathology, parasitology and bacteriology by the Walter Myers lecturer, at the University; (4) of similar instruction on medical entomology by the Lecturer on economic Entomology at the University; and (5) of clinical

lectures and demonstrations delivered at the Royal Southern Hospital by the Physician in charge of the Tropical Ward, the Professor, and the Walter Myers Lecturer.

At the end of each term an examination is held by the University for its Diploma of Tropical Medicine (D.T.M.), which is open only to those who have been through the course of instruction of the school. The examination lasts three days, and consists (1) of three papers on tropical medicine, tropical pathology, and tropical sanitation and entomology respectively; (2) of a clinical examination; and (3) of an oral examination.

The fee for the full course of instruction is thirteen guineas, with an extra charge of ten shillings and sixpence for the use of a microscope, if required. The fee for the examination is five guineas. Applications should be made to the Dean of the Medical Faculty, University of Liverpool, from whom prospectuses may be obtained.

Two University Fellowships of £100 a year each are open to students of the school, amongst others. Accommodation for Research work is to be had, both at the University laboratory of the school, and at its Research Laboratories at Runcorn (sixteen miles distant from Liverpool).

Since it was instituted ten years ago the school has employed thirty different investigators paid out of its funds, and has despatched to the tropics twenty-one scientific expeditions, many of the workers having been taken from among its students. The work done by them has been published in twenty-one special memoirs with many plates and figures, besides text books and numerous articles in the scientific press. From the beginning of 1907, however, the Memoirs have been succeeded by the Annals of Tropical Medicine and Parasitology, published by the Committee, and open to outside contributors (apply to the Secretary, Bio. Exchange Buildings, Liverpool). The Mary Kingsley Medal is awarded by the School for distinguished work in connection with tropical medicine, and has been given to Colonel Bruce, Professor Koch, Dr. Laveran, Sir Patrick Manson, Lord Lister, Professor Looss, Professor Danielewsky, Dr. Charles Finlay, Mr. W. M. Haffkine, Professor Golzi, Colonel Gorgas, Professor Theobald Smith, and Rt. Hon. Joseph Chamberlain, M.P.

#### UNIVERSITY OF BRISTOL.

(The Winter Session commences Monday, Oct. 4th.)

The courses given at the University, and at the allied hospitals, provide full instruction for the degree and diploma examinations in medicine, dentistry, and state medicine. Well-equipped laboratories are now provided for anatomy, physiology, bacteriology, and pathology. Students of the college are admitted to the clinical practice of those very important and well-equipped institutions, the Bristol Royal Infirmary and the Bristol General Hospital. The infirmary and the hospital comprise between them a total of 470 beds, and both have very extensive out-patient departments, and special departments for the diseases of women and children, and of the eye, ear, and throat, besides large outdoor maternity departments and dental departments. Students of the college also have the privilege of attending the practice of the Bristol Royal Hospital for Sick Children and Women, containing 104 beds, and that of the Bristol Eye Hospital, with 40 beds. The total number of beds available for clinical instruction is therefore 614. Very exceptional facilities are thus offered to students for obtaining a wide and thorough acquaintance with all branches of medical and surgical work, and the whole curriculum is now open to women as well as men.

**Appointments.**—At the Royal Infirmary, and also at the General Hospital, clinical clerks and dressers reside in the house in weekly rotation. A pathological clerk is appointed every three months. Also obstetric clerks and ophthalmic dressers. Clinical lectures are given regularly at both institutions.

**Scholarships, Prizes, &c.**—Prizes and certificates of honour are given in University College in all the

subjects of the curriculum. There are one medical entrance scholarship, value £75, awarded annually, two Martyn memorial scholarships (pathology and morbid anatomy) of £10 each, the Tibbits memorial prize, value £9, for proficiency in practical surgery, Henry Marshal prize, £12; Clarke Scholarship, £15; Sanders Scholarship, £22 10s.; one gold and silver medal awarded by the committee, and various prizes for clinical work in surgery and medicine.

**Fees.**—School fees for attendance on all courses of lectures and hospital practice, and including all fees, except vaccination and small charge for board of midwifery student, 133 guineas. If in two instalments, 80 guineas at first session and 60 guineas in the beginning of the second year. Dental composition fee, 75 guineas, including all lectures, practical classes, and hospital practice. Dental mechanical laboratory fee, 75 guineas. Clinical fees (if the composition fee has not been paid)—Surgical practice, one year, 12 guineas; perpetual, 20 guineas. Medical practice, 20 guineas; perpetual, medicine and surgery, 40 guineas.

Prospectus and further information on application to the Dean, Professor Edward Fawcett, M.D.

#### UNIVERSITY OF LEEDS.

The school of medicine attached to this recently incorporated University, was originally founded nearly eighty years ago as the Leeds Medical School. The building, erected on a site contiguous to the infirmary, and opened fourteen years since, contains one of the finest dissecting-rooms in the United Kingdom, extensive laboratories for physiology and pathology with the most recent improvements in fittings and apparatus, ample lecture-room accommodation, a large library, and separate museums for pathology and anatomy. Professors and lecturers are attached, and the clinical teaching is given by the physicians and surgeons attached to the Leeds General Infirmary, one of the largest in the United Kingdom, having 524 beds, with a staff of physicians and surgeons of considerable eminence. Ophthalmic demonstrations and demonstrations of skin diseases are given in the infirmary by surgeons in each department, where also are obtainable various clinical clerkships, dresserships, and other appointments; and an extern maternity charity is attached, at which the necessary attendance at labours can be taken. Besides the infirmary there is a large dispensary, a large hospital for infectious diseases, a hospital for women and children, and a maternity home, all of which are open to students of the school.

**Scholarships, Prizes, &c.**—(1) An entrance scholarship of £73 2s. 6d. There is also a Hardwick prize in clinical medicine, a McGill prize in clinical surgery, each of the value of £10. Thorp prizes of £10 and £5 in forensic medicine and hygiene, and a Scattergood prize of £5 in midwifery, besides silver and gold medals and other class prizes. The composition fee for attendance upon all the required courses of school lectures is £73 2s. 6d. for University students who have attended the preliminary scientific courses, and the same for non-University students, exclusive of chemistry and biology.

At the General Infirmary, the composition fee for medical and surgical practice and clinical lectures is £42 in one sum, or two instalments of £22 each. These fees are not included in the composition fees for lectures and are payable separately.

A scholarship of £42 to cover the cost of medical and surgical practice is offered annually by the Infirmary.

Degrees and Diploma in Dental Surgery are obtainable at this University, being Bachelor of Dental Surgery (B.Ch.D.), and Master of Dental Surgery (M.Ch.D.). Candidates for the degree of Bachelor of Dental Surgery are required to have passed the Matriculation Examination, to have pursued thereafter approved courses of study for not less than five academic years, two of such years at least having been passed in the University subsequently to the date of passing Parts I. and II. of the first examination, and to have completed such period of pupilage or hospital

attendance, or both, as may be prescribed by the Regulations of the University. No candidate shall be admitted to the degree who has not attained the age of twenty-one years on the day of graduation.

Candidates for the diploma in Dental Surgery are required to present certificates showing that they have attained the age of twenty-one years, that they have attended courses of instruction, approved by the University, extending over not less than four years and that they have completed a pupilage of three years, two of such years at least, having been taken before the First Professional examination. Candidates are required to satisfy the Examiners in the several subjects of the following examinations: A preliminary examination in Arts; a Preliminary examination in Science; the First Professional examination; and the Final examination.

A Diploma in Public Health (D.P.H.) is granted after examination under the usual regulations.

#### UNIVERSITY OF SHEFFIELD.

By the Charter granted in 1905, this University is permitted to grant degrees in medicine. All its courses and all its degrees are open, without restriction, to both sexes. The new buildings of the University, opened by his Majesty King Edward in 1905, are situated at the west end of the city, overlooking on two sides the adjoining Weston Park. The medical department occupies the entire north wing of the University quadrangle, and is within easy reach of the various hospitals, with which it is connected for clinical purposes.

These are as follows:—The Royal Infirmary contains 255 beds, with an annual average number of over 3,800 in-patients, over 8,000 out-patients, and over 21,000 casualties; the Royal Hospital, with 172 beds, and an annual number of 2,500 in-patients, over 7,000 out-patients, and over 14,000 casualties; the Jessop Hospital for Diseases of Women, with 80 beds, nearly 500 in-patients, and over 2,000 out-patients; also a Maternity Department, with over 250 in-patients per annum, and over 700 out-patient cases attended. Special courses on fevers are held at the City Fever Hospitals (547 beds), and on Mental Diseases at the South Yorkshire Asylum (1,610 beds).

**Clinical Practice.**—The practices of the Royal Infirmary and Royal Hospital are amalgamated for the purpose of clinical instruction, giving a total of 427 beds for the treatment of medical, surgical and special cases.

**Appointments.**—The following are open to all students who have passed their examinations in anatomy and physiology:—Casualty Dresserships, Surgical Dresserships, Medical Clerkships, Pathological Clerkships, Ophthalmic Clerkships, Clerk to the Skin Department, etc.

**Fees.**—Composition fee of £80, payable in three instalments, viz.:—£24 at commencement of first year of study; £28 at commencement of second year of study; £28 at commencement of third year of study. This composition fee entitles the student to attendance on all the courses of lectures and practical classes, except pharmacy, vaccination, and instruction in anæsthetics required for a degree course in the University, or for the ordinary qualifications in medicine and surgery of the examining boards.

**Composition Fee for Medical and Surgical Hospital Practice.**—Fee for the full period of both medical and surgical hospital practice required by the examining boards:—If paid in one sum at commencement of hospital practice, £42; or if paid in two sums of 21 guineas and 20 guineas, one on beginning hospital practice, the other twelve months later, £43 1s.

**Dental Department.**—In connection with the University there is a complete dental department, which is fully recognised by the various examining bodies, and students are able to get their full curriculum here.

**Scholarships and Fellowships.**—Women's Medical Scholarship, value £100, open to women only; awarded in September, 1909. Entrance Medical Scholarship, value £116, open to both sexes, awarded in June each year. One Medical Scholarship, value 150 guineas, and one Medical Scholarship, value

50 guineas; open to both sexes. One Town Trustees' Scholarship, value £50, tenable for three years, for girls under the age of 19 years. Two Town Trustees' Scholarships, value £60 each, for boys or girls under 19 years of age. Town Trustees' Fellowship, value £75, open to graduates of the University, tenable for one year. Mechanics' Institute Scholarship, value £50, tenable for one year, and renewable for a second year. The Frederick Clifford Scholarship, value about £50 per annum, tenable for two years, open to graduates of the University; and the Kaye Scholarship, value about £22 10s. Gold Medal offered annually for the best student in clinical medicine and clinical surgery. Bronze medals are awarded annually to the students who have gained first place in the examinations for the full course in each year.

**Degrees.**—Candidates for a medical degree must have matriculated in the University or have passed such other examination as may be recognised for this purpose by the University and sanctioned by the Joint Matriculation Board. The subjects required by the General Medical Council must be included in the matriculation examination, or its recognised substitute. The degrees in medicine obtainable are Bachelor of Medicine and Bachelor of Surgery (M.B., Ch.B.), Doctor of Medicine (M.D.), and Master of Surgery (Ch.M.); conditions and particulars of which may be obtained on application to the Dean.

At the University of Sheffield post-graduate courses are held annually. The subjects vary from time to time, and include pathology, bacteriology, physiology, applied anatomy, surgery, operative surgery, ophthalmic surgery, diseases of ear and throat, dermatology, etc. A Diploma in Public Health is also granted by the University.

#### UNIVERSITY OF WALES.

The School of Medicine, in University College, Cardiff, which is one of the constituent colleges of the University of Wales, has since its foundation, in 1883, prepared students for the Preliminary Scientific Examination of the University of London, and for the corresponding examinations of other licensing bodies. In 1893 Chairs of Anatomy and Physiology and a Lectureship in *Materia Medica* and Pharmacy were established, making it possible for students of medicine to spend three out of the five years of prescribed study at Cardiff. Arrangements with the managing committee of the Cardiff Infirmary give students of the College the privilege of attending this large and well-ordered hospital, which is situated within five minutes' walk of University College. Many students, especially from Wales and Monmouthshire, avail themselves of the opportunities thus afforded to pursue the earlier part of the medical curriculum near home. All classes are open alike to both men and women students over sixteen years of age. The courses of instruction given at Cardiff are recognised as qualifying for the examinations of the Universities, Royal colleges, and other licensing bodies of Great Britain and Ireland. Having spent two or three years in study at Cardiff, and having passed the examinations in these years, a student may proceed to London or elsewhere and complete his qualifying course for a University degree or for a college diploma.

Students preparing for the first and second examinations of the Conjoint Board for England, or for the corresponding examinations of the Conjoint Board for Scotland, or for those of the Society of Apothecaries, may compound for their classes by paying a single composition fee of £41 10s., or by paying £20 and £24 10s. at the beginning of their first and second years respectively. Those preparing for the preliminary scientific and intermediate examination in medicine of the University of London may compound for their three years' instruction at Cardiff by paying a single composition fee of £57 10s., or by paying £13 13s., £28, and £21 at the beginning of their first, second and third years respectively.

In 1899 a department of Public Health was established, and lecturers in bacteriology and in public health and hygiene were appointed. Medical men preparing for the diploma in Public Health and Hygiene of the University of Wales can attend complete courses of

lectures and laboratory instruction in this department. These courses are also recognised by the University of Cambridge, by the Royal Colleges of Physicians and Surgeons, and by Victoria University.

In the case of medical students, attendance on the class of hygiene and public health is accepted by the Universities of London and Cambridge, and by the Conjoint Examining Board of England.

Courses of lectures to midwives, adapted to the requirements of the Central Midwives Board, under the Midwives Act, are commenced in October, January, and April. The lectures are suitable both for pupil midwives and practising midwives, as well as for nurses who desire to enter for the examination for certification under the Act.

**Scholarships, &c.**—The attention of students about to matriculate is drawn to the numerous entrance scholarships and exhibitions which are offered at the college for competition in September, most of which may be held by medical students. Full particulars of the examination for these may be obtained from the Registrar, or from the Dean of the Medical Faculty.

#### THE ENGLISH COLLEGES.

THE medical corporations in England are the Royal College of Physicians of London, the Royal College of Surgeons of England, and the Society of Apothecaries of London. The two Royal Colleges now co-operate to hold a series of examinations, on passing which the candidate receives the diploma of Licentiate of the Royal College of Physicians (L.R.C.P.), and Member of the Royal College of Surgeons (M.R.C.S.). The Society of Apothecaries grants a complete diploma (L.S.A.) in medicine, surgery, and midwifery.

#### CONJOINT EXAMINING BOARD IN ENGLAND.

Candidates for the above licences are required to complete five years of professional study at recognised medical schools and hospitals, after passing the preliminary examination, of which six months may be spent at an institution recognised by the Board, to comply with the following regulations and to pass the examinations hereinafter set forth.

**Professional Examinations.**—There are three examinations, each being partly written, partly oral, and partly practical. These examinations are held in the months of January, April, July, and October, unless otherwise appointed, fourteen clear days' notice before the day on which the examination commences being required, the candidate transmitting at the same time the required certificates. The subjects of the first professional examination are Part I., Chemistry; Part II., Physics; Part III., Elementary Biology; and Part IV., Practical Pharmacy. A candidate may present himself immediately after passing the preliminary examination in general education, provided he is able to produce the certificates required. He must present himself for examination in Parts I. and II. together, until he has reached the required standard to pass in both, or in one of these parts, but he will not be allowed to pass in one part unless he obtains at the same time at least half the number of marks required to pass in the other part. A candidate may take Parts III. and IV. separately, or he may present himself for the whole examination at one time. Practical Pharmacy may be taken with, or at any time before Part I. of the Final Examination. Any candidate who shall produce satisfactory evidence of having passed an examination for a degree in medicine in any of the subjects of this examination conducted at a University in the United Kingdom, India, or in a British Colony, will be exempt from examination in those subjects in which he has passed.

The fee for admission to the first examination is as follows:—For the whole examination, £10 10s.; for re-examination after rejection in Parts I. and II., £3 3s.; and for re-examination in each of the other parts, £2 2s.

The subjects of the second examination are anatomy and physiology. Candidates will be required to pass in both subjects at one and the same time. The study of anatomy and physiology will not be recognised

until the candidate has passed in two of the first three parts of the first examination. Candidates will be admissible to the second examination fifteen months from the date of passing the required subjects of the first examination.

A candidate referred at the second examination will be required, before being admitted to re-examination, to produce a certificate that he has pursued, to the satisfaction of his teachers, in a recognised place of study, his anatomical and physiological studies during a period of not less than three months subsequently to the date of his reference.

The fees for admission to the second examinations are: £10 10s. for the whole examination, and £6 6s. for re-examination after rejection.

The subjects of the third and final examinations are:—Part I. Medicine, including medical anatomy, pathology, practical pharmacy, therapeutics, forensic medicine and public health. Candidates who have passed in practical pharmacy at the first examination will not be re-examined in that subject at the third examination. Part II. Surgery, including pathology, surgical anatomy, and the use of surgical appliances. Part III. Midwifery and gynaecology. Candidates may take this examination in three parts separately, or they may present themselves for the whole examination at one time.

Fees for admission to the third or final examination are as follow:—For the whole examination, £21 0s. Part I.—For re-examination in medicine, including medical anatomy, pathology, therapeutics, forensic medicine, and public health, £5 5s.; for re-examination in practical pharmacy (if taken at this examination), £2 2s. Part II.—For re-examination in surgery, including pathology, surgical anatomy, and the use of surgical appliances, £5 5s. Part III.—For re-examination in midwifery and gynaecology, £3 3s.

A candidate referred on the third or final examination will not be admitted to re-examination until after the lapse of a period of not less than three months from the date of rejection, and will be required, before being admitted to re-examination, to produce a certificate, in regard to medicine and surgery, of having attended the medical and surgical practice, or the medical or surgical practice, as the case may be, during the period of his reference; and in regard to midwifery and diseases peculiar to women a certificate of having received, subsequently to the date of his reference, not less than three months' instruction in that subject by a recognised teacher. A candidate who possesses registrable qualifications is admissible to re-examination without producing additional certificates.

#### REGULATIONS FOR COLONIAL, INDIAN, AND FOREIGN CANDIDATES, AND UNIVERSITY CANDIDATES.

Persons holding a Colonial, Indian, or a foreign qualification entitling them to practise medicine in the country of origin, and conferred after a course of study and examinations equivalent to those required by the Royal Colleges, are admissible to the second and third (final) examinations forthwith.

Members of a University in the United Kingdom and Graduates of Medicine of certain recognised Colonial or Foreign Universities, are, under certain conditions, eligible for admission to the third (final) examination two years after passing at their University in the subjects included in the first and second examinations of the Board.

#### ROYAL COLLEGE OF PHYSICIANS OF LONDON.

**MEMBERS.**—The membership of the College is granted after examination to persons above the age of 25 years who do not engage in trade, do not dispense medicine, and do not practise in partnership. This diploma is only granted to persons already registered, or who have passed the final examination for the licence.

Medical graduates of a recognised University are admitted to a pass examination, but others must have passed the examinations required for the licence of the College. The examination, which is held in January, April, July, and October, is partly written and partly oral. It is directed to medicine, and is conducted by the president and censors. Candidates under 40, unless

they have obtained a degree in arts in a British University, are examined in Latin, and either Greek, French, or German. Candidates over 40 are not so examined, and the examination in medicine may in their case be modified under conditions to be ascertained by application to the Registrar. The fee for the membership is £42, but if the candidate is a licentiate £15 15s. is deducted. In either case £6 6s. has to be paid before examination.

#### ROYAL COLLEGE OF SURGEONS OF ENGLAND.

**MEMBERSHIP.**—The candidates are now subject to the regulations of the Conjoint Board.

**FELLOWSHIP.**—The Fellowship of the College of Surgeons is granted after examination to persons at least 25 years of age, who have been engaged in professional studies for six years. There are two examinations—the first in anatomy and physiology, which may be passed after the third winter session; the second chiefly directed to surgery, which may be passed after six years of professional study. The second examination may be passed before attaining the age of 25, but the diploma is not granted until that age is reached. Candidates for this part of the examination must have passed the final examination of the Conjoint Board in England, and have been admitted members of the College before they can be admitted thereto, except in the case of graduates in medicine and surgery of recognised Universities of not less than four years' standing.

**FEES.**—First examination, £5 5s.; second examination, £12 12s. The total fee payable on admission to the Fellowship is £31 10s., except for members, when the fee is £21. (The examination fees to the extent of £17 17s. count as part of the total fee.) Further information can be obtained on application to the Secretary of the Examining Board in England, Examination Hall, Victoria Embankment, London, W.C.

#### SOCIETY OF APOTHECARIES OF LONDON.

**PRIMARY EXAMINATION.**—This examination consists of two parts: Part I.—Elementary biology, Chemistry, Chemical physics, including the elementary mechanics of solids and fluids; Heat, Light, and Electricity. Practical chemistry, Materia medica, and Pharmacy. A synopsis indicating the range of the subjects may be obtained on application. Part II.—Anatomy and Physiology and Histology. The examination is held in January, April, July, and October.

The final examination is held monthly, except the month of September, and is divided into Sections 1 and 2.

Section 1 consists of three parts:

Part I. includes: Principles and Practice of Surgery, Surgical Pathology, and Surgical Anatomy, Operative Manipulations, Instruments and Appliances.

Part II. includes: (a) The Principles and Practice of Medicine, including Therapeutics, Pharmacology, Pathology, and Morbid Histology. (b) Forensic Medicine, Hygiene, Theory and Practice of Vaccination; and Mental Diseases.

Candidates passing either (a) or (b) will not be re-examined therein.

Part III. includes: Midwifery, Gynaecology, and Diseases of New-born Children, Obstetric Instruments and Appliances. Candidates may enter for Parts I., II., and III. together or separately.

Section 1 of the Final Examination, or any part thereof, cannot be passed before the expiration of 45 months from the date of registration as a medical student.

Section 2.—This section consists of two parts:

Part I.—Clinical Surgery.

Part II.—Clinical Medicine and Medical Anatomy. Section 2 cannot be passed before the expiration of the fifth year.

**FEES.**—Primary examination, £5 5s.; final examination, £15 15s.; total fee, £21.

Further information, with particulars as to the course of study and of the certificates required, can be obtained from the Secretary to the Court of Examiners, Apothecaries' Hall, E.C.

This licence is a registrable diploma in Medicine, Surgery, and Midwifery, and qualifies the holder to

compete for medical appointments in the Army, Navy, and Indian Services, also for Poor-law, Civil, and Colonial appointments.

The Gillson scholarship in Pathology of the annual value of £90, tenable for one year, is open to Licentiate of the Society and to candidates for the diploma who obtain it within six months of election to the scholarship. An examination in the art of prescribing is held annually, in January, at which the following prizes are awarded:—A gold medal of the value of £6; a silver medal, and a prize of books to the two best candidates.

### LONDON SCHOOLS.

The Schools of Medicine in the Metropolis are the following, the scholarships, prizes, students' appointments, fees, &c., being set forth in connection with each place named. The names of the hospital staff, lecturers, residential terms, and detailed information will be found, as a rule, in our advertisement columns.

**ST. BARTHOLOMEW'S HOSPITAL.**—This hospital has 750 beds, and for many years past the school attached has had a larger number of students than any other medical school in London. Laboratories have been specially equipped for the study of pathology, bacteriology, chemistry, biology, physics, and chemical pathology, and two additional operation theatres have just been built. A new block of buildings has just been completed at a cost of £120,000, and contains new casualty and out-patients' departments, eight special departments, quarters for the junior staff, a dining hall and a common-room for students, &c. A second new block, devoted to pathology, and containing extensive laboratories for Bacteriology, Clinical Pathology, Pathological Histology, Chemical Pathology, etc., was opened in May, 1909. Collegiate residence is permissible, subject to the ordinary rules.

**Appointments.**—Ten house physicians and ten house surgeons are appointed annually. During the first six months of office they act as "junior" house physicians and house surgeons, and receive a salary of £25 a year. During their second six months they become "senior" house physicians and house surgeons, and are provided with rooms by the hospital authorities, and receive a salary of £80 a year. A resident midwifery assistant, an ophthalmic house surgeon, and a house surgeon for diseases of the throat and nose are appointed every six months, and are provided with rooms and receive a salary of £80 a year. Two assistant anaesthetists are appointed annually, and receive salaries of £120 and £100 a year respectively. An extern midwifery assistant is appointed every three months, and receives a salary of £80 a year. Chief assistants and clinical assistants are appointed in each of the special departments. In-patient dressers, in-patient clinical clerks, clerks, and dressers to the assistant physicians, and assistant surgeons, and to the physicians and surgeons in charge of special departments, are appointed every three months without fee.

**Scholarships, &c.**—There are three open scholarships in science, £75, £75, £150, tenable for one year, and an Entrance Scholarship in Arts, value £100, and the Jeaffreson exhibition, value £50; at the end of first year four junior scholarships of £30, £20, £25, £15, respectively; Treasurer's prize for practical anatomy; Foster prize in practical anatomy; senior scholarship, value £50, for anatomy, physiology, and chemistry; Wix prize, Hichens prize, Lawrence scholarship and gold medal, value 40 guineas, for medicine, surgery, and midwifery; two Brackenbury scholarships, of £30, in medicine and surgery; Bentley prize, for reports of cases; the Kirkes gold medal for clinical medicine, with scholarship of £30. Shuter scholarship of £50; Skynner prize of £15; Sir G. Burrows' prize of £10; Matthews Duncan prize, medal and about £20; Willett medal and Walsham prize; Holden Research Scholarship in Surgery, value £105.

**Composition Fees.**—(1) For students commencing their medical studies, one sum on entrance, 165 guineas; or by four instalments of 45 guineas. (2) For students who have passed an examination in preliminary

science, in one sum on entrance, 145 guineas; or by instalments. (3) For students who have finished two years of medical study but have not passed an examination completing their anatomical and physiological studies; if paid in one sum on entrance, 110 guineas; or by annual instalments. (4) For students who have completed three years of medical study but have not passed an examination in anatomy and physiology, 90 guineas; or by annual instalments. (5) University students who have passed an examination completing their anatomical and physiological studies, in one sum, 80 guineas; or by instalments.

**Fees for preliminary scientific students:**—20 guineas; for laboratory instruction for D.P.H., 15 guineas. Fuller details will be supplied on application to the Dean.

**CHARING CROSS HOSPITAL.**—The school attached to this hospital is situated in Central London, and contains new physiological, pathological, and bacteriological laboratories, materia medica and anatomical museums, an anatomical theatre, enlarged dissecting-rooms, and chemical theatre. Clinical instruction is given in medicine, surgery, and obstetrics, and in the special departments, diseases of the skin, diseases of children, mental disorders, the throat, the eye, nose and ear, and in the orthopaedic, Röntgen and electrical departments.

The school is complete in all departments, with special teachers for all preliminary and intermediate subjects.

**Entrance Scholarships** are awarded annually to the value of £430.

**Appointments.**—The curator and pathologist are appointed annually at £100 a year each. Medical and surgical and obstetric registrars (annual) £40 a year each with luncheon in the hospital. Six house physicians, six house surgeons, and two resident obstetric officers are appointed each year, after competitive examinations. They are provided with board and residence in the hospital.

**Fees.**—The fees for the five years' curriculum may be paid either by composition fee, in one sum, on joining, 115 guineas, or by sessional payment system—Entrance fee, 10 guineas. In addition a sum of 15 guineas must be paid at the beginning of every winter session, and one of 10 guineas at the beginning of every summer session so long as the student remains in the school. Payment may also be made for individual classes and hospital practice when taken separately. Students of any university in the United Kingdom who have passed the examinations in anatomy, physiology, chemistry, and other preliminary subjects, may here complete their studies (except vaccination and attendance at a fever hospital) on payment of a fee of 74 guineas in one sum, or of 80 guineas in two sums, viz., one of 43 guineas on entry, and one of 37 guineas a year later.

The fees for dental students for the two years' curriculum may be paid:—(a) in one sum of 55 guineas on entry; (b) in two instalments—one of 31 guineas on entry; and the second of 30 guineas at the end of the first twelve months.

Prospectus and further information can be obtained on application to the Dean.

**ST. GEORGE'S HOSPITAL.**—This hospital is situated in the West End, facing Hyde Park, and is readily accessible from all parts of London or the suburbs. It has recently undergone extensive alterations and improvements, it has a service 436 beds, of which 100 are at the Atkinson-Morley Convalescent Hospital at Wimbledon, and contains special wards for ophthalmic cases and diseases of women.

**Appointments.**—Eight house physicians and eight house surgeons, entitled to reside and board in the hospital free of expense; twelve general assistants, six assistants in the special departments. Candidates for the above offices are selected quarterly by competition from among the perpetual pupils, sixteen pupils being in office at any one time. Obstetric assistant with a yearly salary at the rate of £50 and board and residence in the hospital; curator of the museum with a salary of £200; assistant curator with a salary of

£100; a medical registrar, with a salary of £200 per annum; a surgical registrar with a salary of £200 per annum; a resident anaesthetist with a salary of £100 per annum; an administrator of anaesthetics with a salary of £50 and two with salaries of £30 per annum. All offices are open to candidates without additional fee.

By arrangement with the University of London, all students for the first, second, and third years of the curriculum carry out the necessary courses of instruction at either King's College or University College. The entire teaching of the school is devoted to clinical subjects.

There are two entrance scholarships in arts and two in science, each of 50 guineas, and two scholarships open to University students, of 70 guineas and £50, particulars of which will be furnished by the Dean.

**Fees.**—For first year, £21 or £26 5s., according to the course. For second and third years, £57 15s. in one sum, or £63 in two instalments. Students entering their names on the books before commencing this preliminary or intermediate subjects pay no entrance fee. Fees for clinical students: Entrance fee, 10 guineas; annual composition fee, 30 guineas.

**GUY'S HOSPITAL.**—This hospital is situated on the Surrey side of London Bridge, and contains 608 beds in constant occupation. There are special wards for ophthalmic and obstetric cases, eight beds in the latter being appropriated for difficult cases of labour. Some beds have also been set apart for diseases of the ear and throat, and an "isolation" ward for cases of infectious diseases arising in the hospital has been constructed. An obstetric registrar and tutor and two clinical assistants and registrars in the ophthalmic department are appointed to augment the teaching in the special departments, in addition to those attached to the general surgical and medical wards. Attached to the hospital is a large residential college with rooms for about sixty men, whilst for students who prefer to live in the suburbs, no other hospital is so conveniently placed, the railway accommodation being good and close at hand. There is a complete School of Dental Surgery at this Institution, which is recognised by the Royal College of Surgeons of England; the facilities thus afforded of completing the whole course of dental study including the pupillage in mechanical dentistry within the walls of one hospital will be appreciated by those intending to practise dentistry. A new museum for pathological specimens and additional lecture and class rooms were opened in 1906.

**Appointments.**—Eight house surgeons, eight house physicians, sixteen out-patient officers, sixteen assistant house surgeons, eight obstetric residents, two ophthalmic house surgeons, twenty-four clinical assistants, and ninety-six dressers are selected annually from the students according to merit, and without payment. There are also a large number of junior appointments, every part of the hospital practice being systematically employed for instruction.

**Scholarships.**—Open scholarships of £100 and £50 in classics, mathematics, and modern languages. Open scholarships of £150 and £60 in chemistry, physics, and biology, and an open scholarship of £50 for University students in two of the following subjects:—Anatomy, physiology, organic chemistry, zoology, physics. The following are the scholarships, prizes, and medals open to students of the hospital:—Junior prizes for general proficiency, £20, £15, £10; Hilton prize for dissection, £5; Michael Harris prize for anatomy, £10; Sands Cox scholarship for physiology, £15; Wooldridge prize for physiology, £10; Beaney prize in pathology, £34; Golding-Bird prize in bacteriology, gold medal and £20; Treasurer's gold medal in clinical medicine; Treasurer's gold medal in clinical surgery; Beaney studentship in materia medica (tenable for 3 years), annually £31 10s.; Gull studentship in pathology (tenable for 3 or 5 years), annually £150. The Arthur Durham travelling scholarship of the value of £100, triennially; Greville Research Scholarship

£200 annually; Oldham Prize in Ophthalmology, £30 annually.

**Fees.**—A new system for payment of composition fees has been instituted at this school. Particulars may be obtained on application to the Dean, Guy's Hospital, London Bridge, S.E.

**KING'S COLLEGE HOSPITAL.**—The hospital is situated close to the Royal College of Surgeons, Lincoln's Inn. There are 220 beds. The student, who pays a composition fee for the whole medical curriculum, carries out his preliminary and intermediate medical studies at King's College, Strand, and enters the hospital when he has passed his examination in anatomy and physiology. The hospital contains special beds for diseases of women, children, eye, ear and throat cases. There are also dental, skin, X-ray, and photographic departments. There are well-equipped pathological laboratories, and the collection of pathological specimens has recently been moved from King's College to the hospital. The various athletic clubs, students' societies, and the Common Room are now under the management of the Clubs and Societies' Union.

**Scholarships.**—One of £50 for University students; four of £50, two in arts and two in science; a senior scholarship for fifth year students, and many special and class prizes are open for competition amongst students.

**Appointments.**—Senior medical, surgical and obstetric tutorships, Sambrooke medical and surgical registrarships, tenable for two years, each £50 per annum. Resident hospital appointments, *vis.*, senior and junior house physicians, physician accoucheur's assistant and assistant house accoucheur, and three house surgeons with free board and residence at the hospital; and senior and junior clinical assistants in special departments every six months.

**F.R.C.S. Examinations.**—Special classes are arranged for the final F.R.C.S. examinations. Further particulars can be obtained post free from the Dean.

**THE LONDON HOSPITAL.**—This hospital is the largest in Great Britain, containing, as it does, 922 beds. It has, moreover, wards and a teaching staff for almost every special department in the domain of medicine; the scholarships and prizes are many and valuable.

**Appointments.**—The salaried appointments open to students are those of medical registrars three, surgical registrars three, obstetric registrars one, medical, surgical, and obstetric tutors; senior dressers to out-patients; clinical assistants in the medical, surgical, ophthalmic, aural, light and skin, orthopaedic, and electrical departments. There are also five resident house-physicians and seven resident house-surgeons, two accoucheurs, seven receiving-room officers, two emergency officers, and three pathological assistants. Also unpaid clinical assistantships in the various special departments. In addition there are numerous assistantships and clerkships, and dresserships in the various departments.

**Scholarships and Prizes.**—At Entrance: Price scholarships in science, £120; in anatomy and physiology, £60; entrance scholarships in science, £60 and £35; Epsom scholarship, £126; Buxton scholarships in arts, £30 and £20. After Entrance: Anatomy and biology scholarships, £20; anatomy and physiology scholarship, £25; Letheby prizes, £30; scholarships in clinical medicine, surgery and obstetrics, £20 each; Duckworth Nelson prize, £10; Hutchinson prize, £40; Sutton prize, £20; Sir Andrew Clark prize, £26; Anderson prizes, £9; out-patient dressers' prizes, £60; practical anatomy prizes, £10; Douro-Hoare prize, £5; Wynne Baxter prize, £5 5s.

A special course for the D.P.H. will commence at the beginning of the winter session.

Special classes for the 1st, and 2nd, M.B.Lond., the primary and final Fellowship, and other examinations are held. Those for the final and primary F.R.C.S. commence on September 1st.

**Fees.**—The composition is 120 guineas. A reduction of 15 guineas is made to sons of medical men.

Special entries can be made either for single courses of lectures or for hospital practice. Residential accommodation is obtainable at a very reasonable

rate close by, or in the suburbs a few minutes' distant by train. Fuller particulars can be obtained of the Warden, Mr. Munro Scott.

**New Buildings.**—The new departments of bacteriology, public health, chemistry, and biology, the new pathological Institute at the hospital, and the new out-patients and special departments are now completed and in full use. New students' rooms have been added, and a garden and fives court opened for the use of the members of the London hospital clubs union. The new Laboratories for Physiology, Chemistry and Physics will be ready for use on Sept. 1st.

**ST. MARY'S HOSPITAL.**—This hospital is situated at Paddington, near the terminus of the Great Western Railway, and at present contains 301 beds, of which 31, recently opened in the Clarence Wing, are devoted to treatment by Therapeutic Inoculation. An additional Operating Theatre has recently been opened in this wing. The Inoculation Department, instituted in 1906, has greatly expanded, and occupies a series of rooms in the New Wing of the hospital.

The Department is under the personal supervision of Sir Almroth Wright, F.R.S.

The Athletic Ground (eight acres) is situated at North Kensington, and is easy of access from the Hospital.

**Appointments.**—All clinical appointments in the hospital are free to students of the Medical School, and the resident medical officers are chosen by competitive examination. Six house physicians, six house surgeons, four obstetric officers, and two resident anaesthetists are appointed in each year, and receive board and residence in the Hospital.

**Scholarships, &c.**—One scholarship in natural science, of the value of £145, open to any gentleman who has not completed a winter session of study at a medical school. Two scholarships each of the value of £50, and one of the value of £25, under the same conditions. Two scholarships, each of 50 guineas, open to students from any British University. The scholarships will be awarded by examination on September 20th, 21st, and 22nd.

**Fees.**—Fee for attendance on the full five years' curriculum of hospital practice and all lectures, demonstrations, and special tutorial classes, £140, paid in one sum on entering the school; or in instalments, £145.

Students who have completed their examinations in anatomy and physiology at the Universities of Oxford, Cambridge, or other University, are admitted as perpetual pupils on payment of a fee of 65 guineas in one sum, or 70 guineas in two annual instalments. University students, prior to completing the anatomy and physiology examinations, pay an annual fee of 25 guineas. After completing the anatomy and physiology examinations, the inclusive fee may be paid.

**Preliminary Scientific Course.**—A complete course of instruction in chemistry, physics, and biology, recognised by the University of London as an approved course for internal students, is held throughout the year. Students may join in October, January, or April.

**MIDDLESEX HOSPITAL.**—This hospital, which is conveniently situated in the centre both of business and residential London, contains 340 beds. There are special departments for cancer, and for ophthalmic, throat, aural, skin, dental, children's diseases, and electrical treatment (X-ray and Finsen light). Wards are also devoted to cases of uterine disease. Residence for students is obtainable in the residential college, which has its frontage on the hospital garden.

A Bacteriological and Public Health Laboratory has been added for the purpose of providing instruction for women medical practitioners preparing for the examinations for the Diploma in Public Health and for the M.D. in State Medicine of the University of London, and of affording facilities to them and other women students desirous of carrying out Research Work in Public Health, Bacteriology, and General Pathology.

**Appointments.**—Casualty surgical officer, casualty medical officer, six house surgeons, six house physicians, and two resident obstetric physicians. The above

officers have residence and board in the college free of expense. Clinical clerks and dressers in all the departments are also appointed in addition to the foregoing.

**Scholarships, &c.**—Three entrance scholarships of the value of £100, £50 and £25, respectively. One entrance scholarship of the value of £50, open to Oxford and Cambridge students only. (Subjects—Anatomy and physiology, including histology.) "Emden" Cancer Research Scholarship, £100. "Richard Hollins," Research Scholarship, £105. Two Broderip scholarships of £60 and £40 respectively, for medicine and surgery; John Murray medal and scholarship, awarded every third year; Hetley clinical prize, value £25, awarded annually for proficiency in practical clinical medicine, surgery, and obstetrics; the Lyell Gold Medal and scholarship, value £55, in surgery and surgical anatomy; the Leopold Hudson prize, value 11 guineas, in surgical pathology, including bacteriology; Freeman scholarship, £30, in obstetrics and gynaecology; an exhibition of 10 guineas for anatomy and physiology to second year's students as well as class prizes in all subjects.

**Fees.**—General fee for the entire course of hospital practice and lectures, 135 guineas, if paid in one sum on entrance, or by instalments of 60, 50, and 35 guineas, payable at the commencement of the first, second, and third years respectively. For those who have completed their anatomical and physiological studies the fee is 70 guineas on entrance, or in two instalments of 40 and 35 guineas. The composition fee for London University students is 145 guineas. For those who have passed the preliminary science examination 120 guineas. The fee for the curriculum for dental students is 54 guineas on entrance, or two instalments of 40 guineas and 20 guineas.

**ST. THOMAS'S HOSPITAL.**—This hospital, with medical school attached, is situated on the southern Embankment of the Thames, facing the Houses of Parliament and contains 602 beds, in constant use. The school buildings, which are separated from the hospital by a quadrangle, comprise numerous theatres, laboratories, and class rooms, which are well adapted for the modern teaching of large bodies of students in all subjects of the medical curriculum. There is a large library and reading-room, and a very complete museum and gymnasium.

**Appointments** are open to all students. A resident assistant physician and a resident assistant surgeon are appointed annually at a salary of £100 with board and lodging. Four hospital registrars, two at an annual salary of £100 each, and two at £50 each, are appointed yearly. The tenure of these offices may be renewed for a term not exceeding two years. Four resident house physicians, two resident obstetric house physicians, and one ophthalmic house surgeon are appointed each six months, also out-patient officers, and clinical assistants in the special departments.

**Scholarships, Prizes, &c.**—Five entrance scholarships are offered for competition in July, viz., one of £150 and one of £60 in chemistry, physics, and biology at the commencement of the second year; one of £50 open to University students who have passed in anatomy and physiology, for a medical degree in any of the Universities of the United Kingdom, and have not entered as students in any London Medical school, and two scholarships in arts giving free tuition for the first year of curriculum. Numerous scholarships, prizes, and medals are open to competition throughout the whole career of a student, including a Fellowship of £100 given by the Salters' Company for research in pharmacology, and the Louis Jenner research scholarship, £60, for pathological research.

Special courses of instruction for the First Professional Examination and Intermed., M.B.Lond., for the Oxford and Cambridge examinations, and for the Primary and Final F.R.C.S. are held throughout the year.

A register of approved lodgings is kept by the medical secretary, who has a list of local medical practitioners and others who receive students into their houses. The prospectus of the school may be obtained

on application to Mr. G. Q. Roberts, Secretary of the Medical School.

**Fees.**—A system for payment of composition fees is in operation. Full details may be obtained of the Secretary.

**UNIVERSITY COLLEGE HOSPITAL AND MEDICAL SCHOOL.**—The hospital with college opposite are situated in Gower Street, not far from Euston railway terminus, and the Medical school in University Street, connected with the hospital by a subway.

**Entrance.**—A student may enter the school as soon as he has passed the University of London Matriculation Examination, or one of the other preliminary examinations that qualify a medical student for entering a medical school. In this case he will pursue his preliminary and intermediate studies at University College, and when those are completed will carry on his final medical studies at University College Hospital Medical School. The student who, in addition to having passed a matriculation or other examination has completed his preliminary and intermediate medical studies at University College or elsewhere, may enter the University College Hospital Medical School for his final medical studies only. Qualified medical men and others who can produce evidence of sufficient qualifications may be admitted to special departments for the purposes of research, or to hospital practice for certain definite periods.

University College Hospital has, through the munificence of the late Sir John Blundell Maple, Bart., been rebuilt and extended in accordance with the requirements of modern medical science. The new hospital accommodates 300 patients, and possesses extensive out-patient and special departments.

Thirty-eight clinical appointments, eighteen of which are resident, are filled up by competition during the year, and these, as well as all clerkships and dresserships, are open to students at the hospital without extra fee.

The new medical school is now completed, and it provides accommodation for lectures and demonstrations and practical work in all the final subjects of the medical curriculum. There are three lecture demonstration theatres for the teaching of morbid anatomy, bacteriology, and chemical pathology; also rooms equipped for the teaching of operative surgery and surgical anatomy, and two large lecture theatres.

The library contains about 10,000 volumes.

The Medical Society, which was founded in 1828 for promoting the study of medical and surgical sciences amongst students, and for social intercourse, has four rooms set apart for reading and recreation, and there is a large gymnasium with baths attached in the school buildings, fully equipped and at the disposal of members of the Society.

**Scholarships, &c.**—Entrance scholarship of the value of 135 guineas, and two exhibitions of 55 guineas each, and the Epsom free medical scholarship for proficiency in science, the subjects being those of the Preliminary Scientific Examination of the University of London, and two of 80 guineas each, the subjects being anatomy and physiology; the Atkinson-Morley surgical scholarship of £45 a year, tenable for three years; the Atchison scholarship, value £55, tenable for two years; Sharpey physiological scholarship, value about £105 a year; Filliter exhibition for proficiency in pathological anatomy, value £30; Erichsen prize, operating case, value £10 10s., awarded for practical surgery; Dr. Fellowes' clinical medals, the Liston gold medal, Alexander Bruce gold medal, Cluff memorial prize, Tuke medals for pathology, and other prizes, as well as certificates of honour, are awarded after competitive examinations in particular branches of study.

**Composition Fees.**—The Preliminary Scientific Course at University College, 26 guineas; Intermediate Course at University College, 57 guineas; final M.B. Course at University College Hospital Medical School, 80 guineas if paid in one sum, or 82 guineas paid in two instalments of 50 and 32 guineas.

**C.—For Dental Students.** Composition fee for the Courses required for the L.D.S., 65 guineas; or exclusive of chemistry, practical chemistry, physics, and materia medica, 50 guineas.

Students may repeat attendance at the Courses in chemistry and physics for £3 3s. (inclusive) and in elementary biology for £2 2s.

It should be noted that under the arrangement with the University of London, that body controls the medical science section of the medical school now, while the advanced medical subjects, that is the subjects after the intermediate course, are controlled by the University College Hospital Medical School.

**WESTMINSTER HOSPITAL.**—This hospital is conveniently situated, facing the Abbey, and is readily accessible from all parts of the Metropolis. It contains 205 beds for general cases, and all the special departments. New school buildings have been erected close by which afford accommodation for 150 students. The class rooms, dissecting rooms, and lecture theatre are excellent samples of modern erections, affording ample scope for study.

**Appointments.**—Medical and surgical registrars, each £50 per annum; two house physicians, three house surgeons, one assistant house physician, one assistant house surgeon, and a resident obstetric assistant. These officers, except the two first named, are all boarded free of expense. Qualified students are appointed to be clinical assistants in the various departments.

**Scholarships, &c.**—(a) Winter Session.—The Guthrie scholarship £60, entrance scholarship £40, entrance scholarship £30, dental scholarship £20; subjects, Latin, mathematics, English, and either Greek, French, or German. University scholarships, 70 guineas, and £60; subjects, anatomy and physiology. Natural science scholarship, £60, subjects, same as for Prel. Sci. of University of London. Natural science scholarship, £40, subjects, chemistry and physics. Free presentation, open to pupils of Epsom Medical College. (b) Summer Session.—Natural science scholarship, £60, same as winter. Natural science scholarship, £40, same as above. Arts scholarship, £60, arts scholarship, £40. University scholarship, £60, subjects same as in winter session. (c) Prizes, to be competed for by unqualified men. Chadwick prize in Medicine and Surgery, 20 guineas, for students of any year not exceeding fifth. Bird medal and prize, in Obstetric Medicine, £14, for students who have completed fourth winter session. Sturges prize in clinical medicine, about £6, clinical surgery prize, £5. Abraham's prize in Clinical Pathology, 5 guineas. And class prizes in the various subjects.

**Fees.**—(a) For course required by Conjoint Board. In one payment of 120 guineas, or two payments of 65 guineas each, payable on entrance and at the commencement of second year respectively, or by six payments, distributed over six sessions, of 24 guineas each. These sums include the subscriptions for membership of the Clubs' Union. (b) For the entire course of the University of London the composition fee is 130 guineas. Fees for shorter periods or for single courses may be learned on application to the Dean. Fees for dental students, payable in one sum on entrance, 50 guineas, or in two instalments, of £27 10s. each.

**LONDON SCHOOL OF MEDICINE FOR WOMEN (ROYAL FREE HOSPITAL).**—The school is situated in Hunter Street, and the Royal Free Hospital is in Gray's Inn Road, close by. Students are prepared for the London University examinations and of the various other Universities. A course of study is also specially arranged for the work required by the Royal Colleges of England, the Conjoint Colleges of Scotland and the Society of Apothecaries of London. The Royal Free Hospital contains 165 beds available for clinical study; and there is a large out-patient and casualty department. In addition to the ordinary systematic lectures at the school, clinical lectures are given at the hospital in medicine, surgery, obstetrics,

ophthalmology, and dermatology. Students hold clerkships and dresserships in each department.

**Appointments.**—A house physician, house surgeon, and a senior and junior resident obstetric assistant are appointed yearly. There are also non-resident appointments, including the anaesthetist and assistant anaesthetists, assistant and clinical pathologists, medical and surgical registrars, curator of museum and clinical assistants.

**Fees.**—The fee for the University of London course and the course for the Royal Colleges of England is £160 in one sum, or £170 if paid in five instalments. The fee for the course for the Conjoint Colleges or Society of Apothecaries, including Elementary Science, is £140 in one sum, or £150 in four annual instalments. Particulars as to Scholarships, &c., can be obtained from the Secretary, Miss L. M. Brooks, 8 Hunter Street, W.C.

**LONDON SCHOOL OF TROPICAL MEDICINE.**—The next session of the school commences on the 1st of October next in the much enlarged laboratories, which had become necessary owing to the increasing number of students who desire to take out the course at the school. The past year has been one of the most successful on record, and for the session ending in July 51 students took out the course. The accommodation of the school treats for only 42 students in the general laboratory, and about five in each of the special departments, thus recently the school has been very much overcrowded. Thanks to the generosity of a friend of the school the laboratories are being enlarged during the long vacation, and it is hoped when the school re-opens there will be sufficient accommodation for all who desire to go through the curriculum. The school provides three sessions each year, and in the future it is hoped that there will be room for 60 students each session. Arrangements are made in the neighbourhood for providing rooms where students can reside, and there is ample accommodation for all who desire to mess in the school.

### EXTRA-ACADEMICAL INSTITUTIONS IN LONDON.

**THE ROYAL DENTAL HOSPITAL.**—The teaching and hospital practice at this institution (situated in Leicester Square) are recognised by the various examining bodies. The new hospital and school which was opened seven years ago, is complete in every detail with modern appliances. The clinic of the hospital is unrivalled, no fewer than 105,000 operations being performed in one year. The following scholarships and prizes are open to all full term students:—Entrance scholarships, of the value of £50 and £25, being awarded in October. Subjects: Chemistry and Physics, Saunders scholarship, of the value of £20, awarded to the student obtaining the highest aggregate number of marks in the various class examinations. A scholarship of £25, the subjects being mechanical dentistry and metallurgy. There is also an Entrance Scholarship of £25 open to those who have studied "mechanical dentistry" under the tuition of a private practitioner. Storer-Bennet research scholarship of the value of £50, awarded once in three years; the Alfred Woodhouse scholarship of £30, and the Robert Woodhouse prize of the value of £10, for practical dental surgery. Class prizes are awarded by the various lecturers. Provision is made for teaching mechanical dentistry, as required by the Royal College of Surgeons, the pupils being under the guidance of the staff of dental surgeons assisted by specially appointed demonstrators. The school contains an excellent library and a well-arranged museum.

**Fees.**—For the two years' hospital practice and lectures as required by the Royal College of Surgeons of England, the fee is £53 3s. in one instalment, or £55 13s. in two yearly instalments. The fee for the complete curriculum, namely, two years' instruction in mechanical dentistry and two years' hospital practice and lectures, is £150 if paid in one sum, or 150 guineas if paid in three instalments of 50 guineas each. For one year's instruction in mechanical dentistry the fee is 50 guineas. For one year's

hospital practice, £21. The necessary course of two years at a general hospital can be taken simultaneously with that at the Royal Dental Hospital. Further particulars can be obtained on application to the Dean.

**NATIONAL DENTAL HOSPITAL.**—This institution is centrally situated (Great Portland Street, W.), and excellent teaching facilities and hospital practice are here obtainable, special demonstrations being given by members of the staff. There are also a mechanical laboratory, bacteriological laboratory, museum, students' common room, a metallurgical laboratory, extraction and stopping rooms, lecture hall, regulations room, &c., all lighted by electricity, and warmed and ventilated after the most approved requirements; in fact, this institution may be pronounced a model dental hospital and school. The winter session commences at the same time as at the medical schools, on October 1st. The medical tutors hold special classes before each college examination. The prizes include two entrance exhibitions, value £40 and £20, and the Rymer prize of £5 5s., the examinations for which are held in May and October. The fee for two years' hospital practice required by the curriculum, including lectures, is £40. (See advt.)

The two years' training in dental mechanics, required by the R.C.S. Curriculum, can be taken in the Mechanical Laboratory, and there is a "Composition Fee" including all the dental subjects of the curriculum of £120.

**THE ROYAL INSTITUTE OF PUBLIC HEALTH.**—The Royal Institute of Public Health, was founded in the year 1886, with the object of obtaining the registration of public health diplomas and the further statutory requirement that all Medical Officers of Health should possess such a qualification, by which means it has succeeded in placing at the head of every public health administration in the Kingdom, a properly trained and specially qualified medical officer. The Council, with the object of providing a Central Institution in London, not only for instruction for the diploma and for scientific work in connection with public health, but also one to which those engaged or interested in preventive or tropical medicine may resort have acquired large and important premises in Russell Square, for the purposes of the Institute, providing a common room for the use of Fellows and Members, a lecture room, a reference library, laboratories for bacteriological and chemical and physical research, and laboratories in which the course of instruction for the diploma in public health can be taken, fitted up with all modern improvements. The Institute is recognised as a public educational institution by the University of London, and its courses of instruction by the Universities and the Royal Colleges of Physicians and Surgeons.

**Medical students are admitted to the practice of the following Metropolitan and Special Hospitals to which no medical school is attached. Detailed particulars will be supplied on application to the various secretaries.**

**GREAT NORTHERN CENTRAL HOSPITAL,** Holloway Road, N.—This institution has been greatly enlarged, contains 179 beds, cases in various special departments are treated, and the hospital is now recognised for study during the fifth year by the Conjoint Board. The practice of the hospital is open to practitioners and senior students, and clinical and pathological assistants are appointed in the wards and out-patient departments, as in the larger general hospitals.

**WEST LONDON HOSPITAL,** Hammersmith Road, W.—(Only qualified medical men are admitted to the practice of this Hospital). This hospital contains 160 beds, and has an extensive out-patient department. Three house surgeons and three house physicians are selected every six months. There are special departments for diseases of the throat, nose and ear, skin, women and children, and deformities. Electrical and X-ray departments have also been added. The practice of this hospital is reserved exclusively for medical men, junior students not being admitted.

**BETHLEM ROYAL HOSPITAL.**—In this Royal institution only cases of lunacy are received, and students intending to pursue this special branch have the best possible opportunities afforded here. The hospital contains 300 beds, and two resident house physicians who have recently obtained their diplomas to practise medicine and surgery are elected every six months, and are provided with apartments, complete board, attendance, washing, and an honorarium of 25 guineas per quarter. The students of certain specified London medical schools receive clinical instruction in the wards of the hospital, and qualified practitioners may attend for a period of three months on payment of a fee. Post-graduate lectures are also given.

**NATIONAL HOSPITAL FOR EPILEPSY AND OTHER DISEASES OF THE NERVOUS SYSTEM,** Queen Square, W.C., contains 200 beds. This institution is recognised by the Conjoint Board where part of the fifth year of study may be devoted to clinical work. Clinical clerks are appointed to the physicians for out-patients, and courses of lectures and clinical demonstrations are given each year.

**LONDON TEMPERANCE HOSPITAL.**—The hospital contains 110 beds, and is conducted as its name implies on non-alcoholic principles by an excellent staff. The medical and surgical practice is open to students and practitioners. Appointments (vacancies for which are advertised in the medical journals): Surgical and medical registrars, resident medical officer, and one assistant resident medical officer.

**METROPOLITAN HOSPITAL,** Kingsland.—This was until recently known as the Metropolitan Free Hospital, is situated in the north-eastern district of the Metropolis, and contains 160 beds. It is a general hospital, with various special departments for the treatment of diseases of the eye, throat, ear, &c.

**PRINCE OF WALES HOSPITAL TOTTENHAM.**—This hospital contains medical and surgical wards and a ward for children, having in all 73 beds. There are special departments for gynaecological cases, diseases of the eye, ear, throat and nose, and skin diseases. It has now been authorised by the University of London to give certificates of post-graduate study for the M.D. and M.S. degrees.

#### HOSPITALS FOR CONSUMPTION.

**HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST,** Brompton.—The largest institution for the treatment of affections of the chest in the United Kingdom, there being 318 beds in the two buildings. There are four house physicians who reside in the hospital, each for a period of six months. Lectures and demonstrations are given by members of the medical staff on Wednesdays and Fridays at four o'clock, save during the vacations. Terms, £2 2s. for three months; £5 5s. perpetual. This hospital is recognised by the Conjoint Board, the University of London, and the Apothecaries' Society.

**MOUNT VERNON HOSPITAL,** Hampstead and Northwood.—This institution, formerly called the North London Consumption Hospital, now carries on its work at Hampstead with 145 beds, and at Northwood with 100 additional beds, where treatment is carried out on the most modern lines, including the "open air" and other systems. Students are admitted to the practice of the hospital under certain conditions, and post-graduate courses are regularly delivered during the year.

**CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST,** Victoria Park.—This is a large and well-equipped hospital at the East End, containing 176 beds. Clinical lectures and demonstrations are given by the members of an exceptionally experienced staff. Fee for three months' attendance on hospital practice, 2 guineas; six months, 3 guineas.

**ROYAL HOSPITAL FOR DISEASES OF THE CHEST,** City Road.—(80 beds.)—This hospital has been enlarged by the addition of a very complete out-patients' department, and also by the erection of a new wing, which provides accommodation for 80 in-patients.

#### THROAT AND EAR HOSPITALS.

**METROPOLITAN EAR, NOSE, AND THROAT HOSPITAL.**—This hospital was founded so far back as 1838, and

is situated in Grafton Street, Tottenham Court Road. The out-patient department is open daily at 2.30 p.m. to practitioners and students for acquiring clinical instruction and technical knowledge. Operations are performed on in-patients on Tuesdays, Wednesdays, Thursdays and Fridays at 9.30 a.m. Fee for one month's attendance at the hospital one guinea, and for three months two guineas. During the forthcoming session demonstrations will be given by members of the staff on the pathology and treatment of diseases of the ear and respiratory passages. Weekly clinical lectures are given by the staff on the special disease treated at the hospital.

**HOSPITAL FOR DISEASES OF THE THROAT,** Golden Square, W.—This hospital has been recently rebuilt and contains 40 beds. Clinical instruction is given daily in the Out-patient Department on diseases of the nose, throat, and ear, and systematic courses of lectures are given during the winter session. There are nine clinics weekly, and an annual out-patient attendance of nearly 50,000. Major and minor operations daily (Mondays excepted) in different theatres. Four senior and thirty-six junior clinical assistants are appointed from among the students to assist the surgeons. Students are admitted to the practice of the hospital at the following fees:—Three months, £5 5s.; six months, £7 7s.; longer periods, £10 10s. Further details can be had by applying to the Hon. Med. Secretary.

**CENTRAL LONDON THROAT AND EAR HOSPITAL.**—This hospital contains accommodation for 26 in-patients. It has a very extensive out-patient department (over 50,000 attendances yearly), which is open daily to all medical practitioners and students, for the purpose of clinical demonstration and instruction. Courses of practical teaching are held twice weekly by members of the staff, which are open to qualified practitioners and advanced students. Each course is of about seven weeks' duration, and includes hospital attendance for that period.

Operations are performed daily (Saturday excepted) at 2 p.m. Special attention is devoted to scientific work in the newly-equipped laboratory. Full particulars will be supplied on application to the Dean.

#### WOMEN AND CHILDREN.

**HOSPITAL FOR SICK CHILDREN,** in Great Ormond Street, Bloomsbury, and Cromwell House, Highgate.—Fee for three months' attendance, £3 3s.; perpetual, £5 5s.; £1 1s. for students satisfactorily undertaking clinical clerkships for not less than three months. There are now 222 beds, besides 38 additional at the convalescent branch.

The practice of the Hospital is open to qualified medical men, and to students who have completed four years of medical study, the Hospital having been recognised by the Conjoint Board of England as a place where six months of the fifth year may be spent in clinical work. There are special ophthalmic, aural, dental, and electrical departments. There is also a Museum and Library in connection with the School. Lectures are given every Thursday afternoon during session by members of the staff, and certificates are granted.

For tickets and further information, apply to the Secretary, by letter, or by calling at the Hospital.

**QUEEN CHARLOTTE'S LYING-IN HOSPITAL,** Marylebone Road, N.W.—Qualified medical practitioners and medical students are admitted to the practice of this hospital. Certificates of attendance are recognised by all universities, colleges and licensing bodies. Fee for the course of four weeks, £8 8s. Students are accommodated at the new Residential College (5, Cosway Street) opposite the hospital.

Arrangements have also been made for the preliminary instruction in midwifery now required by the General Medical Council. This will include:—(1) Practical instruction in the methods of examination of pregnant women; (2) delivery of women in labour under the direct supervision of a medical officer of the hospital; (3) practical instruction in the treatment of the mother and child during the puerperium, in-

cluding clinics held four times weekly by the visiting medical staff. Fee for this special course for the month will be £5 5s.

**ROYAL WATERLOO HOSPITAL FOR CHILDREN AND WOMEN.**—This important institution, situated in South London has been rebuilt and appointed on completely modern lines, and now provides 90 beds.

**THE SAMARITAN FREE HOSPITAL FOR WOMEN** Marylebone Road, N.W., offers excellent opportunities to qualified medical men for clinical study and training in the details of operative gynaecology. Fee: Three months, £3 3s. The success of the staff in this department has gained for them a European reputation. There are 51 beds.

**THE HOSPITAL FOR WOMEN, Soho Square.**—The hospital contains 61 beds. In connection with this institution there is now an organised school of gynaecology open to qualified medical men and to students after their third year. Clinical assistants to the physicians and surgeons in the in-patient and out-patient departments are appointed every three months. Fee for the three months' course, and certificate, £8 8s.

**CHELSEA HOSPITAL FOR WOMEN, FULHAM.**—This institution contains 50 beds, and is served by a staff of considerable eminence. In connection with it there is a Convalescent Home at St. Leonards, in which 22 additional beds are at the disposal of the authorities.

#### EYE HOSPITALS.

**ROYAL LONDON OPHTHALMIC HOSPITAL,** formerly in Moorfields, and recently rebuilt in the City Road, is the largest hospital devoted to this specialty in Great Britain, and contains 138 beds. Students and practitioners are admitted to the practice daily at 9 o'clock. Operations, 10 o'clock and after. Fee for six months, £3 3s.; perpetual, £5 5s. Further particulars of the Secretary.

**ROYAL WESTMINSTER OPHTHALMIC HOSPITAL,** adjoins Charing Cross Hospital in King William Street. It has about 40 beds and a very large out-patient *clinique*. The lectures and demonstrations are arranged with special reference to the requirements of practitioners and senior students. Fee, six months, £3 3s.; perpetual, £5 5s.

**ROYAL EYE HOSPITAL, St. George's Circus, Southwark.**—There are 40 beds and two cots. Fees, £2 2s. for three months, £3 3s. for six months, and £5 5s. perpetual. Courses are held on ophthalmoscopy, refraction, and diseases of the eye; fee, £1 1s. for each course, but perpetual students may attend each course once without extra fee. Pathology class, £1 1s. extra to cover cost of materials.

**CENTRAL LONDON OPHTHALMIC HOSPITAL.**—This hospital is situate in the Gray's Inn Road, has 26 beds and a large out-patient *clinique*. The post of clinical assistant is open to both men and women, who must be duly qualified and registered practitioners. During the winter session commencing in October lectures and demonstrations will be given in all the branches of ophthalmology. For syllabus and further particulars apply to the Dean.

#### SKIN HOSPITALS.

**ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN.**—Out-patient department, Leicester Square; In-patient department, Uxbridge Road, W. This hospital has a well-equipped in-patient department, with 45 beds. It has a School of Dermatology at 49 Leicester Square, which is conducted by the medical staff of the hospital. During the past year the free course of Chesterfield Lectures have been well attended. The Out-patient Department has recently been rebuilt at a cost of £10,000, and contains a spacious laboratory and special electrical department which can be seen in operation every afternoon except Saturday. Clinical demonstrations are given every Monday at 2 p.m.; Tuesday at 2 p.m., Wednesday at 3 p.m.; Thursday

at 2 p.m., and Friday at 2 p.m., on Selected Cases. (See Advt.)

One of the oldest institutions of the kind is the Western Skin Hospital (Great Portland Street), which was started as long ago as 1851. The practice of the hospital is open to students and practitioners. Students of this specialty have also the London Skin Hospital, in Fitzroy Square, with seven beds and an out-patient department of over 1,400.

#### METROPOLITAN POST-GRADUATE INSTITUTIONS.

**MEDICAL GRADUATES' COLLEGE AND POLYCLINIC.**—This institution affords to medical men special facilities for acquiring technical skill, and advancing their medical and scientific knowledge. The building, which is large and commodious, is situated in Chenies Street, Gower Street, and contains lecture and consulting rooms, pathological and clinical laboratories, Röntgen ray room, an ophthalmoscope room, a library and museum, and reading and smoking rooms. *Cliniques*, at which patients are shown, are given every day of the week except Saturday, at 4 p.m. Lectures on Medicine, Surgery, and other allied subjects are delivered on Mondays, Tuesdays, Wednesdays, and Thursdays at 5.15 p.m. Four sessions of practical classes, each lasting six weeks, and a vacation session of three weeks' duration, are held during the year, the subjects taught comprising ophthalmology, otology, clinical microscopy, laryngology, urinary analysis, gynaecology, applied anatomy, nervous diseases, and practical X-ray work. There are, in addition, extra-mural classes in operative surgery and practical anatomy with dissecting. Special tutorial classes in medicine, surgery, midwifery, and pathology for gentlemen reading for the higher qualifications have recently been instituted, and are conducted regularly throughout the year.

The annual subscription for medical practitioners of either sex is One Guinea. Full information may be obtained from the medical superintendent, Major Vint, M.B., 22 Chenies Street, Gower Street, W.C.

**WEST LONDON POST-GRADUATE COLLEGE.**—The West London Hospital, Hammersmith Road, W., contains 160 beds; the post-graduate course was started in 1895, and this is the original post-graduate college in London attached to a general hospital. Instruction is given in the out-patient department daily at 2.15 p.m. by the assistant physicians and assistant surgeons. The physicians and surgeons attend daily at 2.30 p.m., when post-graduates can accompany them in their visits to the wards. Operations are performed daily at 2.30 p.m. There are lectures every evening at 5 p.m. (Saturdays excepted). Special classes are held in bacteriology, diseases of the eye, throat, X-rays, anaesthetics, intestinal surgery, tropical medicine, cystoscopy, operative surgery, &c.

**Fees.**—The fee for the hospital practice including all the ordinary lectures and demonstrations, is £1 1s. for one week; £3 3s. for one month; £6 6s. for three months; £9 9s. for six months; £15 15s. for one year, and £25 for a life ticket. A course of attendance on either the medical or surgical practice alone may be taken out for the fee of £4 4s. for three months. The fee for three months' attendance in any one special department, other than medicine or surgery is £3 3s. A prospectus containing full particulars will be forwarded on application to Mr. L. A. Bidwell, Dean.

**NORTH-EAST LONDON POST-GRADUATE COLLEGE.**—This post-graduate school is established in connection with the Prince of Wales's General Hospital, Tottenham, N., which is recognised by the University of London as a place of post-graduate study for the M.D. and M.S. degrees, and by the Admiralty and the India Office for purposes of study leave. Facilities are here afforded to qualified medical practitioners for taking part in the work of an active general hospital, and for attending demonstrations in various branches of medicine, surgery, and gynaecology, with opportunities for clinical instruction in diseases of the eye, ear, throat, nose, skin, in fevers,

psychological medicine, the administration of anæsthetics, radiography and dentistry. Cliniques, lectures and demonstrations are given by members of the teaching staff in the lecture room, in the wards, in the various out-patient departments, and in certain affiliated institutions. Operations are performed every afternoon of the week, except Saturday. Special classes, the attendance at which will be limited, are arranged in gynaecology, the surgical diseases of children, including orthopaedic surgery, diseases of the throat, nose and ear, diagnosis of diseases of the nervous system, ophthalmoscopy and refraction, analysis of gastric contents, clinical examination of the blood, diseases of the skin, abdominal surgery, radiography, bacteriology (which is accepted by the University of Cambridge for the D.P.H. diploma) and medical electricity. The fee for a three months' course of study, which may be begun at any time, in any single department, is one guinea. A fee of three guineas admits to the whole practice of the hospital for a similar term (one month, 2 guineas), and a perpetual ticket for the practice of the hospital may, for the present, be obtained on payment of a fee of 5 guineas. The opening lecture of the Winter Session will be given by Mr. J. Bland-Sutton at 4 p.m., on Thursday, October 7th. Additional information with a syllabus of lectures, demonstrations, and special classes, may be obtained from the Dean of the Post-Graduate College, Dr. A. J. Whiting, at the Hospital, or at 142 Harley Street, W.

**LONDON POST-GRADUATE ASSOCIATION.**—This Association offers facilities for Clinical Study to qualified medical men. Joint cards of admission are issued to the Clinical Instruction of the following General Hospitals and Schools of Medicine:—Charing Cross, Guy's, Westminster, St. Thomas's, University College, St. Mary's, King's College, besides several special hospitals. *Fees.*—For three months, 10 guineas; for six months, 15 guineas; and for any longer period at the further rate of 9 guineas for each additional six months. Further particulars may be obtained of the Secretary, London Post-Graduate Association, Examination Hall, London, W.C.

**THE LONDON SCHOOL OF CLINICAL MEDICINE** is entirely reserved for qualified practitioners, no unqualified students being allowed to attend its clinics and classes. The school is held at the Seamen's Hospital, Greenwich, with which are affiliated for teaching purposes the Royal Waterloo Hospital for Children and Women, the Bethlem Hospital, and the General Lying-In Hospital, all within the South-Eastern district. The Dreadnought Hospital is situated at Greenwich, and contains 250 beds, which are continually occupied by patients suffering from every variety of disease. It provides annually for 2,000 in-patients and 19,000 out-patients. The out-patient department at the Dreadnought Hospital is supplemented by the Society's dispensaries in the East India Dock Road, and at Gravesend, at which the present annual attendance is approximately 4,000 patients. The hospital is easily reached from London:—(a) By train from Charing Cross or Cannon Street to Greenwich Station, which is within five minutes' of the hospital. (b) By train from Charing Cross or Cannon Street, or from District and Metropolitan Stations to New Cross, and thence by electric tram (seven minutes). Out-patient clinics are held in surgery, medicine, and the special departments every morning; whilst in the afternoons ward clinics are given in medicine, in surgery, and in one of the special departments. Operations are performed daily. The fee for attendance on the ordinary practice of the hospital provides for admission to the wards, operating-theatres, post-mortem rooms, out-patient rooms, and clinics; and practical classes are arranged each session in all the usual subjects of medicine and surgery.

**The following are some of the principal provincial hospitals having the greatest number of beds, to which students are admitted where clinical in-**

**struction can be obtained, but to which there is no medical school attached:—**

**ROYAL BERKSHIRE HOSPITAL.**—The town of Reading, in which this hospital is situated, has a very large working-class population, and excellent opportunities for clinical instruction in the wards and extensive out-patient department are afforded here. It contains 160 beds, a splendid library, in which the Reading Pathological Society holds its meetings.

**BRADFORD INFIRMARY.**—The hospital contains 220 beds. Non-resident pupils are received and abundance of clinical material is obtainable. One year's attendance is recognised by the Examining Boards. Fee, perpetual, £10 10s.

**ROYAL DEVON AND EXETER HOSPITAL, Exeter.**—This hospital contains 200 beds (including special children's wards), and numbers on its staff several well-known names; has a good library. Attendance on the practice of this hospital qualifies for all the examining boards, and students can attend Midwifery on application to the House Surgeon. Arrangements may also be made by which practitioners may have the use of the museum and library, and other facilities.

**LEICESTER INFIRMARY** is duly recognised by the various examining bodies, and contains 198 beds (to be shortly increased to 230), and at the Children's Hospital in connection 42; total, 240. A new wing containing 100 beds has recently been added, and a new Nurses' Home is in course of erection.

**LIVERPOOL NORTHERN HOSPITAL**, which has recently been rebuilt, now contains 240 beds, and is completely equipped with the most modern appliances. Clinical instruction is given by the staff during the summer and winter sessions. Clinical clerkships and dresserships are open to all students without additional fees. Fees for hospital attendance: Perpetual, £26 5s.; one year, £10 10s.; six months, £6 6s.; three months, £4 4s.; practical pharmacy, £2 2s.

**THE LIVERPOOL SKIN HOSPITAL AND EXTRA-MURAL SCHOOL OF DERMATOLOGY**, in Pembroke Place, has eight beds and an Out-patient Department where over two thousand different patients are registered annually, and is open to Senior Students and Practitioners of Medicine. There is an excellently equipped "Light" Department where instruction is given in X-Ray and Finsen Light Therapy, and attached to the Hospital is a Museum of Dermatology. Terms for private instruction, 10 guineas per month.

**NORFOLK AND NORWICH HOSPITAL.**—This hospital is recognised by the Colleges, and contains 210 beds. Fees, £10 10s. for six months, £15 15s. for twelve months' medical and surgical practice. Pupils, resident and non-resident, are admitted.

**NORTH STAFFORDSHIRE INFIRMARY, Hartshill, Stoke-on-Trent.**—This institution is built on the pavilion plan, and has accommodation for over 200 patients, including children's wards, women's wards, and a special department for the treatment of diseases of the eye, so that there are excellent facilities here for acquiring a practical knowledge of the profession.

**NOTTINGHAM GENERAL HOSPITAL.**—As a large commercial and industrial centre, Nottingham boasts of a large general hospital and several special institutions. The General Hospital contains 241 beds, and is staffed by several well-known physicians and surgeons. The practice is open to qualified members of the profession, and house appointments obtained hereat yield valuable material for study, especially in the direction of accidental injuries.

**SUSSEX COUNTY HOSPITAL, BRIGHTON.**—This hospital possesses about 200 beds, as well as a large out-patient department, and a well-appointed clinical research and bacteriological department. Hospital practice may be gained here for a period not exceeding two years on payment in advance of a fee of 20 guineas. There is also an excellent library attached.

**WOLVERHAMPTON GENERAL HOSPITAL.**—The hospital contains 210 beds, attendance at this hospital being recognised by all the Examining Boards. Pupils are trained in clinical work by the medical and surgical staff. *Fees:* Six months, £6 6s.; twelve months, £10 10s.; perpetual, £21.

## Ireland.

### THE IRISH MEDICAL SYSTEM.

THE system of medical teaching in Ireland differs from that in England in important particulars. In London each clinical hospital has its attached medical school, which is fully equipped, and which educates the students of that hospital and very seldom those of any other. In Dublin, on the contrary, the hospitals and schools are entirely separate (except that Sir Patrick Dun's Hospital is officially connected with Trinity College), and a student of any school is free to enter for the whole or any part of his course at any school or hospital he pleases.

#### COST OF MEDICAL EDUCATION IN IRELAND.

The cost of obtaining a medical qualification depends to some extent on the qualification sought. In this connection the following tables may be of use to the prospective student:—

#### COST OF MEDICAL EDUCATION.

School of Physic, Dub. Univ. ...	£122 17s.
Royal College of Surgeons School ...	£124 19s.
Catholic University School ...	£124 19s.
University Colleges ...	About £110
Queen's University, Belfast ...	£104

#### COST OF DIPLOMAS OR DEGREES.

Dublin University	—	£27 (to this must be added £83 4s., the cost of obtaining an Arts degree).
Royal University	—	£15.
Conjoint Royal Colleges	—	£42.
Apothecaries' Hall	—	£22 1s.

Thus, the absolute payment will amount to somewhere between £125 and £233 1s. according as the teaching of the University Colleges and the degrees of the Royal University, or the teaching and degrees of Dublin University, are taken. For the Conjoint Colleges the entire cost is £166 19s., taking the minimum mode of payment. So that, assuming that extras or voluntary costs are incurred, the total will vary, say, from £170 to £200. "Grinding," although not officially recognised, occupies a position almost identical with that of the extra-mural instruction of other schools. Its cost must be reckoned among the expenses of the course, for, while not essential, it has become customary for almost all students to obtain aid in their studies in this way. As a rule, this private instruction costs about £5 5s. for each of the four examinations.

The above sum, or something like it, may be expended by the student or his parent in paying for lectures, &c., and examination fees as they fall due, and there is no difficulty in obtaining the needful information for his guidance if he likes to pay for his course in this fashion.

All the Dublin schools require fees for each course to be paid in advance.

Women are admitted to all the courses, degrees, and licences on the same terms as men.

#### DATE OF ENTRY.

The entry of names and commencement of study in Ireland is supposed to date from the 1st of October in each year, but entries are accepted up to the end of that month, or in some schools even later. It should be remembered that no credit is given for studies or attendance until the entry is regularly made. The student must attend three-fourths of the lectures delivered, and if he loses any time at the beginning he must make up for it afterwards by constant attendance.

The student begins work by attending a recognised medical school each morning at ten o'clock, and occupying his day, to five p.m., between lectures and dissections. His vacations are a fortnight at Christmas and a fortnight at Easter, and the academic year ends at the end of June.

#### PRELIMINARY EXAMINATIONS.

The first act of the student is to pass a preliminary examination, without which he cannot get credit for any medical studies pursued. The next is to commence medical study. This he does by entering for lectures

at a medical school. From the school registrar he gets a form of certificate, and his third act is to take it or send it to the Branch Medical Council, 35 Dawson Street, Dublin, unless, as is usually the case, this duty is undertaken for him by the school registrar. He is thereupon placed upon the Register of Medical Students (without fee), and his period of study counts from that date. He must register at the earliest possible moment, or he may lose credit for his work.

The only preliminary examination held specially for medical students is that held conjointly by the Royal Colleges of Physicians and Surgeons, but other examinations, e.g., the public entrance at Trinity College, the matriculation of the Royal University, the Intermediate Examination passes in the required subjects, and certain other examinations recognised by the General Medical Council, are accepted as equivalent.

The subjects of examination as prescribed by the General Medical Council are as follows:—1. English language, including a specified author, dictation, grammar, and composition; also parsing and analysis from a book specified. 2. Latin, including grammar, translation from specified authors, and translation of easy passages not taken from such authors. 3. Elements of mathematics, comprising (a) arithmetic, including vulgar and decimal fractions; (b) algebra, including simple equations; (c) geometry, Euclid, Books I., II., and III., with easy deductions. 4. One of the following optional subjects:—(a) Greek, (b) French, (c) German.

#### THE IRISH LICENSING BODIES.

The Medical Licensing Bodies of Ireland are five in number, and, as a rule, students will gravitate into one or other of five classes:—a. Those who enter Trinity College, and take a full graduation in Arts in addition to their professional degrees. b. Those who take the licence of the conjoint Royal Colleges of Physicians and Surgeons. c. Those who take their qualifications at the Royal University of Ireland, where graduation in Arts is not necessary. d. Those who enter Queen's University, Belfast, and take their course and degrees there. e. Those who take the licence of the Apothecaries' Hall. f. Those who pursue their studies in Ireland, but who migrate to London, Edinburgh, or Glasgow for their licences. Almost all these last-named emigrants come from the Queen's Colleges, and the greater number of them from Belfast, while the Dublin students qualify, as a rule, in Dublin.

We do not attempt to give details as to the requisite courses of instruction for degrees or diplomas, as our epitome must necessarily be insufficient for the information of the student, and we can occupy our available space with information more useful to him. The official information upon which students may depend can be obtained by sending a note to the Registrars of the Licensing Bodies or Schools.

Note.—It is necessary to note that, consequent on the passing of the recent Universities Act, the Royal University will soon cease to exist. Its place will be taken by the new National University, having constituent University Colleges in Dublin, Cork, and Galway, and the Queen's University situated in Belfast.

#### THE UNIVERSITY OF DUBLIN.

The University of Dublin grants the degrees of M.B., B.Ch., and B.A.O. to students who have obtained their Arts degree, and who have been for at least five academic years on the books of the Medical School, and the higher degrees of M.D., M.Ch., and M.A.O. to graduates of certain standing who hold the degrees of M.B., and B.Ch. It does not grant degrees to any but graduates in Arts, and consequently its degrees hold the highest rank of social and educational qualifications, and are sought for by those who look forward to occupying the best positions in the profession.

The expense of obtaining the degrees of M.B., B.Ch., and B.A.O. is approximately as follows:—Lectures, £67 4s. 6d.; Hospitals, £55 13s.; Degree Fees, £27.—Total, £149 17s. 6d.

The expense of the B.A. degree, amounting altogether to £83 4s., should be added, making the total cost £233 1s. 6d.

In addition to its ordinary qualifications the University grants the following higher degrees:—

**Doctor of Medicine.**—To obtain this the candidate must have passed the final examinations, and be of M.A. standing. He must then read a thesis before the Regius Professor of Medicine. Fee for this degree, £13.

**Master of Surgery.**—The candidate must be a Bachelor in Surgery of three years' standing, and must then pass an examination in clinical surgery, operative surgery, surgical pathology, surgery, and surgical anatomy (on the dead subject). Fee for this degree, £11.

**Master in Obstetric Science.**—The candidate must have passed the M.B. and B.Ch. examinations, and have completed, in addition to the courses for M.B., B.Ch., a course of obstetric medicine and surgery. He is then required to pass an examination in the following subjects:—Practice of midwifery, gynaecology, anatomy of female pelvis and elementary embryology, and clinical gynaecology. Fee for this degree, £5.

**Diplomate in Medicine, Surgery, and Midwifery.**—Candidates for the diplomas in Medicine, Surgery, or Obstetric Science must be matriculated in Medicine, and must have completed two years in Arts and five years in medical studies. The medical course and examinations are the same as for the degrees. Fees for the diplomas in medicine, surgery, and midwifery, £21. A diplomate, on completing his course in Arts and proceeding to the degree of B.A., may become a Bachelor of Medicine on paying the degree fees.

**Diploma in Public Health.**—The candidate must be an M.D. or a Graduate in Medicine and Surgery of Dublin, Oxford, or Cambridge, or an M.D. of London University; must have completed, subsequent to obtaining a registrable qualification, six months' practical instruction in a laboratory in practical work in chemistry and bacteriology applied to public health; he must have studied practically outdoor sanitary work for six months under an approved Officer of Health; and have attended, after qualification, for three months, the practice of a hospital for infectious diseases.

**Degree and Licence in Dental Science.**—Candidates for the degree in dental science must have taken a degree in Arts, and must have had their names in the books of the Medical School for five years. Two examinations must be passed—namely, the Previous Dental at the end of the second year, and the Final Dental at the end of the fifth year. Candidates for the Licence are required to matriculate in Arts, and pass one Term Examination. The course of study is the same as for the degree with the exception that no lectures in pathology or bacteriology are required. The total fees for the licence, including the premium for Dental Mechanics (£100), are £200 17s., while those for the degree are about £210, to which must be added the cost of the B.A. degree.

**Post-Graduate Classes.**—A short post-graduate course is now given annually in June and July in connection with Trinity College Medical School. It includes special work on Diseases of the Eye, Nose, and Throat, Gynaecology, Diseases of the Skin, X-ray work, Medicine, Surgery (clinical and operative), and Clinical Pathology.

**Royal Services School.**—The object of this school is to prepare candidates for the Indian Medical Service, and Royal Army Medical Corps. It is conducted on a comprehensive scale, and affords special opportunities for operating on the cadaver, and for the study of commentaries. Two sessions are held yearly, each lasting for about ten weeks.

#### THE ROYAL UNIVERSITY OF IRELAND.

The Royal University of Ireland is purely an examining body. The cost of the M.B. and B.Ch. of the University, with all the necessary curriculum, is about £125. Some of the Arts examinations are conducted, not only in Dublin, but at certain local centres.

The University confers the following medical degrees:—

M.B., B.Ch., B.A.O., and the higher degrees of

M.D., M.Ch., and M.A.O. It also confers a Diploma in Public Health and a Diploma in Mental Diseases.

All courses are open to persons of either sex who shall have passed either the Matriculation Examination of the University or the Senior Grade Examination of the Intermediate Education Board for Ireland in the subjects prescribed for the Matriculation Examination of the University, and who shall apply for exemption from the Matriculation Examination in the year in which they shall have passed such examination.

The University examinations are held in the spring, beginning about the middle of April, and in the autumn, beginning towards the close of September.

All candidates for any degree must pass the Matriculation examination, or the Senior Grade Examination or the Intermediate Education Board (as above mentioned) and the First University examination.

The course for the degree of M.B., B.Ch., B.A.O., extends over five years.

Students will be admitted to the First University examination after one year from matriculation. Fee, £1.

The medical course consists of three previous examinations, one at the end of each year, and one degree examination at the end of the fifth year. Fee for each previous examination, £1; for the degree examination, £2; for the diploma, £10.

In addition, the following degrees are granted:—

**Diploma in Public Health.**—Conferred only on graduates in medicine of the University of at least twelve months' standing. Fee, £2. Subjects.—Meteorology, bacteriology, chemistry, physics, vital statistics, hygiene, sanitary engineering, architecture and law.

**The M.D. Degree.**—Conferred only on graduates in medicine of the University of three years' standing. They must at the same time produce a certificate of having been, for at least two academical years, engaged in hospital or private, medical, surgical, or obstetrical practice, or in the military or naval medical service. The examination comprises medical diseases and the theory and practice of medicine, including pathology. Every candidate will be examined at the bedside, and be required to diagnose at least three medical cases, and prescribe treatment, and to write detailed reports on at least two cases to be selected by the examiners and to discuss the questions arising therefrom. Fee, £5.

**The M.Ch. Degree.**—Conferred only on graduates in medicine of the University of three years' standing, and who can produce a similar certificate of practice to that required for the M.D. degree. The examination comprises surgery, both theoretical and operative; surgical anatomy; ophthalmology and otology. Fee, £5.

**The M. A. O. Degree.**—Conferred only on graduates in medicine of the University of three years' standing, and who can produce a similar certificate of practice to that required for the M.D. and M.Ch. degrees. The examination comprises midwifery and diseases of women and children. Fee, £5.

**Note.**—As stated above, this University will soon cease to exist. It is unlikely that any examination will be held after January 1, 1910.

#### NATIONAL UNIVERSITY OF IRELAND.

The regulations of this new body are not yet published. Its constituent Colleges are to be situated at Dublin, Cork, and Galway, and each College will have the right of conducting examinations which will carry with them the degree of the University. It is probable that the lines of the Royal University will to some extent be followed.

#### ROYAL COLLEGES OF PHYSICIANS AND SURGEONS.

These examinations are held conjointly by the two Colleges. The course, as in other bodies, extends over five years, with examinations at the end of the first, second, third, and final years. These examinations are conducted by examiners chosen by each of the Colleges for the subjects appropriate to them. The curriculum has recently been revised, and made of a more practical nature. In

common with the English Colleges, the subjects of the First Professional examination may be studied either at a medical school or at an institution other than a medical school recognised by the Colleges, after due inspection, for instruction in these subjects. We recommend students to apply for the official programme to the Secretary of the Committee of Management, Royal College of Physicians, or to the Registrar of either College. In the case of the Preliminary Examination seven clear days' notice must be given to the Secretary; fourteen days' notice is required from candidates for the Professional examinations.

The total of the examination fees, spread over the four examinations, is £42, while the school and hospital fees, if taken in Dublin, amount to £124 19s., making altogether £166 19s., exclusive of re-examination fees, which have to be paid in case the candidate fails to pass his examination.

The Conjoint Colleges also confer a diploma in Public Health, of which information will be found on page 259.

#### ROYAL COLLEGE OF PHYSICIANS, IRELAND.

This College issues a Licence in Medicine and a Licence in Midwifery to Registered Medical Practitioners.

*Licence in Medicine.*—The subjects of examination are:—Practice of Medicine, Clinical Medicine, Pathology, Medical Jurisprudence, Midwifery, Hygiene and Therapeutics.

*Licence in Midwifery.*—The subjects of examination are:—Gynaecology and Midwifery. A Registered Medical Practitioner of five years' standing is exempted from the examination by printed questions.

*Fees.*—Fee for the Licence to Practise Medicine £15 15s. Fee for the Licence to Practise Midwifery £5 5s.
